signal at 2,000 m is much greater than the noise level, we see that the signal is not due to eddy noise. The only other error potentially of concern is in the depth inference; the IGY data depths are based upon reversing thermometers and those for the 1981 data upon a pressure sensor. The expected discrepancies can be shown to be less than about 10 m, well below the observed displacements.

The hydrographic station data can also be used to calculate geostrophic velocities and volume transports. Figure 3 shows horizontally-integrated transport per unit depth across 24° N (1981 data). Geostrophic shear together with mass conservation

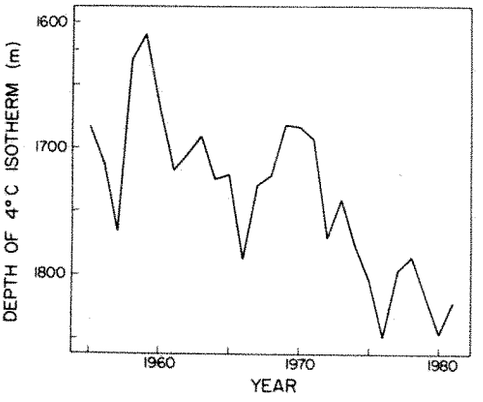

Fig. 4 Annual mean depth of 4 °C isotherm at the RV *Panuliris* station (32°10′ N, 64°30′ W).

constraints were used to estimate geostrophic velocity using an inverse method[9]. On the whole, surface and intermediate waters flow northward. Deep water flows southward in two lobes from its source regions in the Labrador and Greenland Seas and there is a small northward flow at the bottom. An interesting question is whether the observed water-mass shifts can be seen as the divergence of mass and/or heat transports. If the observed loss of mass in the 2–4 °C range was spread out evenly over the 23 yr between surveys, then a mass flux divergence of about 2×10^9 kg s^{-1} would be required. Relative to the transports of Fig. 3, which are of the order of 10^{10} kg s^{-1}, this value is too small to be detected reliably in geostrophic calculations. Similarly, the heat flux convergence required to add 0.1 °C to a layer 2,000 m thick is about 1×10^{13} W, which is only about 1% of the total northward heat flux across 24° N.

What is the proper time scale of the hydrographic changes we have described? Some deep water masses are thought to form only sporadically[3], with new formation being absent for years or longer. Are the differences we observe due to a 'sloshing' in the North Atlantic, measured in years, or are they part of a long term trend of expansion and contraction of water masses?

A simple north–south displacement of isotherms can be ruled out as the cause of the observed changes. The 4 °C isotherm depth is near its maximum value at 24° N. One can see this from meridional sections of temperature along 50° W and 66° W[1]. No north–south displacement could increase the 4 °C depth by 100 m, as was observed in 1981.

Unfortunately, there are very few long time-series of measurements with which to address the time scale problem. The Panuliris station has been occupied regularly to depths of about 2,000 m since 1955. We analysed these data by interpolating each station to locate the depth of the 4 °C isotherm and then averaging all stations in a year. The 4 °C isotherm was chosen because of its large observed displacement in our study. The annual means of 4 °C isotherm depth (Fig. 4) show a clear trend, increasing by the order of 100 m over 25 yr. This evidence supports the hypothesis of a long time scale in our observations. At temperatures warmer than 4 °C, up to the waters where a long-term cooling has been previously described[7], any possible

trends were obscured by eddy noise, which is large in this part of the Atlantic.

The present study is limited to the subtropical North Atlantic Ocean. Nevertheless, the questions that it raises are global. (1) Is the average temperature of the oceans increasing? Climate models which couple an atmosphere with a stratified ocean[10] show ocean warming in response to the global increase of atmospheric carbon dioxide, but warming of the model oceans is concentrated near the surface, in contrast to our results. (2) Can the global rise in sea level, reported to be 10 cm per century[11], be attributed to thermal expansion of the deep ocean? The thermal expansion coefficient of seawater is about 1.6×10^{-4} per °C at 5 °C, 35‰ in salinity, and 200 bar[12]. Thus, a column of water 1,000 m thick, heated by 0.1 °C gains nearly 2 cm. In the 1981 investigation, the water from 70 to 300 bar was thicker than in the IGY data by an average of 3 cm at 24° N and 2 cm at 36° N. Whether such changes occurred elsewhere in the world oceans is unknown.

CTD data were collected by the Woods Hole CTD group under the supervision of Dr M. McCartney. Captain Jorgensen and the crew of the RV *Atlantis* were most helpful. The work was supported by the NSF under grant OCE-80-185140 to the MIT and grant OCE-81-21262 to the University of California, San Diego.

Suspended particulate organic material from hydrothermal vent waters at 21° N

Paul B. Comita & Robert B. Gagosian*

Department of Chemistry, Woods Hole Oceanographic Institution, Woods Hole, Massachusetts 02543, USA

Peter M. Williams

Ocean floor spreading centres described recently consist of several sites with chemical and biological features unlike any oceanic sites previously known[1–4]. The high-pressure and warm-temperature regimes at these sites, coupled with dynamic hydrothermal water circulation, support biological communities that utilize a source of primary production which appears to be non-photosynthetic[5]. A detailed biochemical analysis of the suspended matter at a biologically-active site has been undertaken, with the goal of describing the relationship between microorganisms, benthic organisms and suspended particulate material within these hydrothermal systems. Suspended particulate matter from warm hydrothermal vent waters (5–38 °C) of the East Pacific Rise[1–4] (21° N, 106° W) was sampled on the OASIS expedition with an *in situ* pumping system in April 1982. Particulate organic carbon (POC) and nitrogen (PON) as well as individual organic compound classes from the lipid fraction were analysed to ascertain the sources and composition of the organic matter in this highly productive area. We show here that the particulate organic material (POM) of the vent water was both quantitatively and qualitatively different from the non-vent bottom water. The POC and PON measured within the vent and non-vent waters vary by a factor of 2–5, the higher values being in warm water. The organic matter in the non-vent water was found to be more resistant towards degradation or remineralization than in the vent water, as shown by the C:N ratio and the total lipid:POC ratio. Contributions to the lipid class compounds were assessed using well-known organic compound source biomarkers such as hydrocarbons, fatty alcohols, sterols, triacylglycerols and steryl and wax esters.

The hydrothermal vent sampling site was ~50 m^2, located adjacent to a collapsed lava lake. Twin peaks of 'black smoker' vents ($T \sim 270$ °C), a large 'white smoker' vent ($T \sim 10$–44 °C), and several other features were located in this area. Suspended particulate material from this site was sampled with an *in situ* pumping system. Four of the six filters were direct samples of warm (15–40 °C) hydrothermal vent water, and were from the following sites: (1) two from a hole located in the pillow basalt (dives 1212 and 1214) and (2) two from the base of a dense growth of vestimentiferan worms (*Riftia*) located adjacent to the white smoker (dives 1223 and 1220). One sample was of water intermediate in location and temperature between the warm vent water and non-vent bottom water (5 °C, above a bed of *Calyptogena magnifica*, dive 1212). The final sample was of non-vent bottom water at the vent site (2 °C, dive 1228). This sample will be referred to as the non-vent water sample. The *in situ* pumping system used to sample the particulate material consisted of a peristaltic pump, three solenoid valves, a polyethylene water bag, a five-in-one filter holder, a stainless steel single filter holder, and a computerized controller with associated electronics and power supplies. The pumping system was deployed from DSRV *Alvin* and sampled the hydrothermal vent water by directing the nozzle into a warm water source. Temperature readings of the water were made using a thermistor probe on *Alvin*. The vent water was pumped through Gelman type A/E glass fibre filters (GFF) at a rate of 1.6 l min^{-1}. The average sample size was ~150 l. The filters were previously combusted at 450 °C and Soxhlet extracted with 1:1 v/v toluene/methanol (MeOH) for 12 h. These filters retain >95% of particles of >1.0 μm diameter[6]. As previous studies indicate

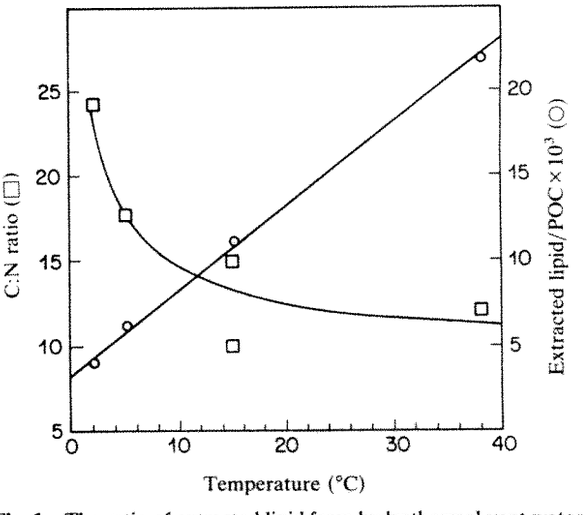

Fig. 1 The ratio of extracted lipid from hydrothermal vent water particulate material (μg l^{-1}) to the particulate organic carbon (μg l^{-1}) from the same sample, plotted as a function of water temperature, and the ratio of particulate organic carbon (μg l^{-1}) to particulate organic nitrogen (μg l^{-1}) plotted as a function of water temperature.

nature is keeping ahead.

Are you being left behind?

New research results, the very latest international science news, key papers by the world's leading scientists and speed of publication ensure *Nature* remains one of the foremost weekly scientific journals in the world.

But if you're tied in to a circulation list at work, all this vital weekly information will undoubtedly reach you late, often incomplete and sometimes not at all.

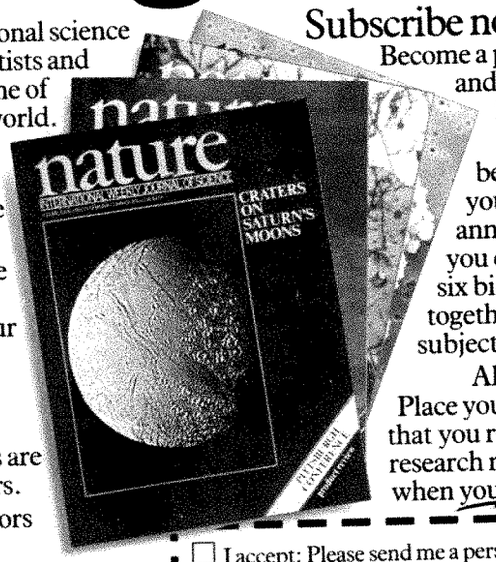
With your own personal copy, you solve the problem. Every week you'll have all the latest research results and science news in your hands within days of publication:

News reports from throughout the world of science and technology.

A **News and Views** section, where new ideas are analysed and discussed by leading researchers.

Articles and Letters in which key investigators disclose their work for the first time.

Book Reviews – Eminent figures offer expert judgments on a wide variety of recent publications.



Special Issues providing an in-depth treatment of topics of importance.

Product Reviews – Detailed descriptions of laboratory equipment newly available.

Classified Advertisements for a wide variety of positions all over the world.

You will no longer be dependent upon other people passing down the 'list' copy, and because you will automatically receive every issue, you won't risk missing a single copy through absence from work. Moreover, you keep all this key information for permanent reference.

Through your door every week

Subscribe now – at Half Price

Become a personal subscriber now and you will receive a discount of 50% off the full rate.

All 51 weekly issues will be delivered to the address of your choice. You can start your annual subscription with any issue you choose. And you will receive six bi-monthly author indexes, together with the annual index of subject and author.

All this for just 94p a week.

Place your order now and make certain that you receive the scientific news and research results crucial to your work when you want them.

☐ I accept: Please send me a personal subscription to *Nature* for one year (51 issues) at the special half-price rate of £49.00.

☐ I enclose my personal cheque for £49.00 made payable to *Nature*. (Note: Institutional cheques cannot be accepted at this special rate).

☐ Please charge to my credit card account.

Circle No.90 on Reader Service Card

MICRO '84

a meeting for scientists and technologists interested in a wide range of microscopical instrumentation and applications, will be held at the Bloomsbury Crest Hotel and the London School of Pharmacy from 9th-13th July, 1984.

ORGANISATION OF MICRO

Every two years, the Royal Microscopical Society holds its main scientific conference associated with a large trade exhibition. When drawing up the programme, the organisers have to bear in mind the multi-disciplinary needs of the fellowship, all of whom use microscopy as an essential tool. In order to achieve this, a lot of time is spent deciding on these areas where development is taking place most rapidly such as the introduction of new equipment or expansion of existing areas by development of new methodology. Parallel with this is the need to provide strong themes passing through the week to provide continuity for those scientists who wish to attend for the whole week.

INPUT FROM THE FELLOWSHIP

The Society's activities can be sub-divided into five main sections. These comprise electron microscopy, light microscopy, materials science, histochemistry and subjects of common interest such as the use of computers. The interests of the biologists as well as the material scientists are catered for in several of the areas mentioned above. Each section has a committee which runs the meetings and courses during the year and which also has a distinct input into the Micro programme. In this way, it is ensured that the whole spectrum of microscopical instrumentation and applications is considered.

CHOICE OF THE VENUE

The choice of the venue is inevitably a compromise between the needs of the participants to have a number of lecture theatres on the same site, easy to reach from most parts of the country and allowing free interchange between symposia. In addition, the choice of the Exhibition area has to be based on size, cost and again proximity to the lecture theatres to allow ready access. The timing of the programmes includes a long luinch break for visits to the Exhibition between the sessions. The Bloomsbury Crest Hotel has been used by the Society several times and is now well known to most of the delegates.

Circle No.17 on Reader Service Card.

INSTRUMENTATION

So what does Micro '84 have to offer to the participant? First and foremost, there is a good coverage of instrumentation including established and novel designs. For the electron microscopist there are several sessions including both SEM and TEM where the state of the art will be covered either as lectures or in the form of tutorials which are being introduced for the first time. This should encourage discussion on design, usage, testing performance and obtaining the best results. Data capture in the microscope and analysis are discussed by a number of experts, as are associated techniques such as X-ray analysis and EELS.

Other microscopical systems of interest are X-ray microscopy, laser doppler microscopy, acoustic microscopy, scanning optical microscopy and cryo-microscopy. X-ray microscopy is a rapidly developing field as is acoustic microscopy, both benefitting from the introduction of new and improved manufacturing methods and sources of X-rays such as the synchrotron. The Society has been fortunate to obtain speakers in these fields who have been foremost in pioneering the introduction of these novel systems.

COMPUTER-ASSISTED DATA HANDLING

The use of computers to assist the microscopist has grown rapidly as in other scientific fields and they are used either in association with collection of data within the microscope itself, as a data-storage component such as with X-ray microanalysis or as a means of analysing such data either collected directly or after taking data from micrographs to give quantitated results. All of these systems have been used both to speed up data collection and analysis and to obtain more meaningful results from the data so analysed.

PRACTICAL APPLICATION

Whereas a proportion of the people attending Micro '84 will be interested in developments in instrumentation, another significant population will be scientists wishing to refresh their ideas as to the many applications of microscopy. As this covers a wide range of knowledge and background, some broadly based lectures and complete sessions have been included such as methods for handling specimens, or the two days devoted to immunocytochemistry, a vital tool for the immunologist. Industrial users have been considered whether they are interested in semiconductors, crystallography or pharmaceutical applications. The academic scientist, on the other hand, will find many lectures pertinent to a wide range of subjects.

THE IMPORTANCE OF THE EXHIBITION . . . HELD IN ASSOCIATION WITH NATURE

All in all, this Micro promises to be of a high scientific standard and wide interest. To a large extent this is due not only to the enthusiasm and interest of the scientists responsible for putting together the programme and 'persuading' the experts to come and share their knowledge, but also the very loyal support and help of the Trade Committee which helps to co-ordinate what is the world's most comprehensive exhibition of microscopes and accessory equipment. As a result, the Society can direct any would-be user or buyer to the appropriate group of manufacturers; in return the income from the exhibitors' fees (there is no entrance fee) assists speakers to travel from all over the world to produce the best programme possible for the Society and its supporters.

* C/N (weight) 1.167 = C/N (atom).

that >60% of the ATP biomass resides on particles >12 μm in hydrothermal vent waters[5], the filters should sample a large fraction of the particulate organic material from this source.

Particulate organic carbon and nitrogen were analysed by filtering several litres of the vent water (collected in polyethylene bags) through a stainless steel filter holder containing two 25-mm Gelman type A/E GFFs which had been previously combusted at 500 °C. The POC and PON determinations were accomplished using a CHN analyser.

The particulate material was also analysed for lipid class compounds using methods previously described[7]. The filters were weighed and ~25% of each was sonicated and extracted with methylene chloride (CH_2Cl_2)/MeOH/H_2O. The lipid extract was then partitioned between CH_2Cl_2 and H_2O. The CH_2Cl_2 extract was evaporated to dryness under vacuum at <25 °C. Hexane was then added and elemental sulphur was removed on a short column of activated copper particles (105–250 μm diameter)[8]. The sulphur-free extracts were separated into individual compound classes by adsorption chromatography. Elution with a series of solvents of increasing polarity separated the lipids into alkane and alkene, polyunsaturated alkene, steryl and wax ester, triacylglycerol, fatty alcohol, and steroid alcohol fractions. The alcohols were converted to their respective acetates with acetic anhydride in pyridine. The individual fractions were spiked with appropriate external standards for quantitative determinations and analysed by high resolution glass capillary gas chromatography (GC) using a deactivated, cross-linked SE-52 coated (25.5 m × 0.32 mm i.d.) column. Compound structures were identified by comparison of GC retention times (alkanes, wax esters, and triacylglycerols) and mass spectra with authentic standards (fatty alcohols and steroid alcohols)[9]. Procedural blanks performed concurrently with these analyses indicated <1% contamination in each fraction.

The bulk chemical properties from the *in situ* pump samples are listed in Table 1. Water temperature roughly increased from the pillow basalt sample (dive 1228) of 2 °C non-vent water at the vent site, to 5 °C for the sample collected above the clam bed (dive 1221), to 15–38 °C for the directly sampled warm vent waters. The concentration of both POC and PON increased with increasing water temperature, but not in the same proportion. The total lipid extract (TLE) also increased with increasing temperature (Table 1). Similarly, the ratio of (TLE:POC) × 10^3 ranged from a value of 4 in the non-vent bottom water to values of 11–50 in the hydrothermal vent waters (Fig. 1). A comparison of these POC and PON values with other values found in the world's ocean is informative. Western North Atlantic surface coastal POC values are ~100 $\mu g\,l^{-1}$, whereas open ocean POC values are ~50 $\mu g\,l^{-1}$ (ref. 9). Wangersky found POC values for surface waters (0–100 m) of 54 $\mu g\,l^{-1}$ for the South Atlantic and 30 $\mu g\,l^{-1}$ for the Pacific Ocean[10]. At depths >3,000 m the POC value was ~5 $\mu g\,l^{-1}$ (refs 10, 11) for both the South Atlantic and Pacific Oceans. In the central North Pacific gyre, POC values range from 2 to 4 $\mu g\,l^{-1}$ (ref. 11). Off the coast of Peru, a productive upwelling site, POC values range from 100 to 700 $\mu g\,l^{-1}$ in surface waters[12]. The values for warm vent water POC are in the region of 200 $\mu g\,l^{-1}$ indicative of a relatively productive site.

The C:N ratio ranged from a value of 24.3 for non-vent bottom water to values of 10–15 in the warm vent water samples (Fig. 1). The values for the vent water C:N ratio are higher than expected for normal marine bacteria or phytoplankton (~5–6)[13], but similar to deep sea suspended POM. The C:N ratio for hydrothermal vent organisms, however, is not known. Values for dissolved organic carbon (DOC) for the warm vent water samples range from 0.64 to 0.85 $mg\,C\,l^{-1}$, somewhat lower than non-vent water (1.01 $mg\,C\,l^{-1}$).

Each filter analysed for lipids was qualitatively different. In general, the samples collected from lower temperature water contained less macroscopic particular material than samples from higher temperature water. The three warm vent water filters were each qualitatively different from one another. Two had numerous large zooplankton, copepods (Spinocalanidae new genus and species[14]) on filter 1214, and amphipods (genus *Onesimus* sp. (C. Ingram and R. Hessler, personal communication) on filter 1223. These large zooplankton were removed before analysis, as their lipids would dominate those present in the particulate material, masking any potential information in the particulate matter lipid fingerprint. Microscopic zooplankton and parts of zooplankton may still have been present on the filter when analysed, however, and may have contributed to the organic material on the filters. The filter with the highest amount of lipid had no large zooplankton or microscopic organisms when viewed with a ×50 magnification dissecting microscope. This filter had a relatively small amount of water pumped through it apparently because it became plugged due to a large amount of inorganic particulate material.

Five individual compound classes are listed in Table 2 for the five filters analysed for lipids. In general, the lipid fraction of vent samples was dominated by sterols, triacylglycerols, and wax esters (>90% average). The concentrations of all lipid classes increased as the temperature of the water sampled increased. The ratio of an individual compound class to POC was lower in the non-vent water than in the warm vent water (see dive 1228, Table 2), as was noted previously for the ratios of total lipids to POC.

The aliphatic hydrocarbons make up, on average, <3% of the total lipid classes analysed. The major components typically centred around C_{19} or C_{20} (Table 2). The *n*-alkanes dominate this compound class without any marked odd/even carbon predominance. A large unresolved complex mixture indicative of weathered organic material was present in every sample[15]. There

* CPI, carbon preference index. Odd/even for aliphatic hydrocarbons.

† The numbers indicate carbon number in order of decreasing abundance. Where the numbers are in the form $x:y$, x = number of carbons and y = number of double bonds.

‡ 1 is cholest-5-en-3β-ol, 2 is cholesta-5,24-dien-3β-ol, and 3 is 24-methylcholesta-5,24(28)-dien-3β-ol.

appears to be no clear distinction between the *n*-alkane distribution in the non-vent and vent water samples that would allow a distinction to be made about the source of the alkanes. The large amounts of aromatic hydrocarbons found in sediments at Guaymas Basin (23–32% of lipid extract)[16] were not present in the particulate material from warm vent waters at 21 °N. This observation, and the large amounts of what appear to be locally biosynthesized lipid compounds (see below), indicate little rapid thermal alteration of organic matter on the suspended particulate material at this vent site. We do not mean to imply that thermal alteration of organic matter does not occur at the 21 °N hydrothermal vents. However, the contribution of thermally altered organic compounds (in the form of aliphatic and polycyclic aromatic hydrocarbons) to the suspended particulate material is in fact very small. Markers for microbial activity in this compound class, such as hopanes[17], isoprenoid hydrocarbons[18], or sterenes[19], were also not present within our limits of detectability.

Free fatty alcohols also make a relatively small contribution to the total lipid (5% average), and were dominated by typical marine biomarker C_{16}, C_{18}, and $C_{18:1}$ alcohols (>74% average)[20]. The minor components were typically C_{14}, $C_{16:1}$, $C_{20:1}$ and C_{24} and on average comprised 12% of the total fatty alcohols. The free fatty alcohols exhibited a high even-to-odd carbon preference (>50).

Both the wax ester and triacylglycerol compound classes make up a large portion of the lipid fraction of organic material (average 56%). The major contribution to the wax ester fraction, $C_{34:1}$ and C_{32}, are typical marine zooplankton wax esters[21]. The high level of these compounds is not surprising considering the large number of macroscopic zooplankton collected from the warm vent water samples. These high values may reflect zooplankton input to the POM or may simply be parts of macroscopic zooplankton or microscopic zooplankton present on the filters that were not picked off. We are unable to distinguish between these two possibilities with our methodology. The concentration of wax esters in open ocean particulate matter, determined with the Woods Hole *In Situ* Pump (WHISP), is 14 ng l^{-1} (S. G. Wakeham, personal communication) for surface waters from 18° N, 108° W, a moderately productive environment. By comparison, the average of the three vent water values was 240 ng l^{-1}; the non-vent water sample was ~3 ng l^{-1}. Clearly, the vent particulate matter samples contain over an order of magnitude higher concentration of wax esters than moderately productive surface waters. The warm vent water samples contained both wax and steryl esters, whereas the non-vent and intermediate water filters 1228 and 1221 contained only wax esters, suggesting a warm water source for the steryl esters. This source may be a different species of organism contributing to POM sampled in the warm vent waters.

The steroid alcohols also comprised a major fraction of the total lipid (average 35%). The vent waters were dominated by three sterols (96% total sterols), cholest-5-en-3β-ol (cholesterol), cholesta-5,24-dien-3β-ol (desmosterol), and 24-methylcholesta-5,24(28)-dien-3β-ol (24-methylenecholesterol). Non-vent water samples contained mainly cholesterol, typical of other oceanic bottom waters[22]. The simple distribution of sterols in the vent water samples is not typical of seawater samples previously studied[9,22]. Pure cultures or single species of organisms usually biosynthesize several major sterols[23]. The simple pattern found for the vent samples most probably indicates a select number of single sterol sources. The higher concentration of sterols in warm water relative to non-vent water samples may indicate either an organism source solely living in the warm water or a gradation of productivity between vent and non-vent water. The distribution of the vent water sterols is very similar to that found for molluscs[24], suggesting that the clam *Calyptogena magnifica* may be the source. The sterols of *Calyptogena magnifica* are cholesterol, cholestanol and three minor sterols (not identified). This distribution clearly does not match that of the POM, but the sterol composition of the vestimentiferan worm matches extremely well. The major three sterols of the vestimentiferan worm are cholesterol, desmosterol, and 24-methylenecholesterol. 24-methylcholesta-5,22E-dien-3β-ol and 24-ethylcholesta-5,24(28)Z-dien-3β-ol, sterols known to have a phytoplankton source, were detected in extremely small amounts relative to other sterols.

The initial results from our studies have uncovered several interesting features. All of the vent water samples that we have analysed showed an enrichment of POM relative to non-vent bottom waters. This organic material was both quantitatively and qualitatively different between the non-vent water and vent water, that is the C:N ratio decreased from non-vent to vent

water indicating that the organic material in the non-vent water is more resistant, and represents the less-labile, carbon-rich fraction of the vent POM. The ratio of total lipid/POC also confirmed this conclusion. The lipid class compounds, one of the more labile forms of organic matter, make a larger contribution to the vent water organic carbon than to the non-vent water organic carbon.

The change in concentration of particulate organic matter at this site appears to be a very localized event. In this investigation all samples, including the non-vent sample of bottom water, were taken within an area that was actively emitting warm water and sustaining a large population of benthic organisms. The POC and PON levels measured within the warm waters and in the non-vent water at the vent site vary, in general, by at least a factor of 2–5, the higher values being in warm water. Observations from *Alvin* indicate that the vent organism at 21 °N live in or extremely near to a source of warm vent water, a feature common to other vent sites as well. Our analyses reflect this phenomenon and indicate that primary sources for organic carbon are localized in or near the warm vent water site[25].

The relative contribution to the POM by microbial versus animal carbon sources may be partially assessed by using our data on the organic compound source biomarkers. The wax esters, triacylglycerols, and sterols dominate the lipid fraction. The wax ester, triacyglycerol, and fatty alcohol compound classes that were present in the suspended particulate material are typical of marine zooplankton. Indeed, many amphipods and copepods were found in vent waters and collected in our *in situ* pump filters. The sterol distribution on the particulate material matches that of the *Riftia*. The microbial component of the lipid fraction cannot be completely resolved with our data set. Microbially produced lipids, such as hopanols and isoprenoid hydrocarbons, were not found on the filters. Fatty acids, and the more polar phospho- and glycolipids are in the process of being analysed, and these compound classes may contain a large fraction of microbial source markers. Another interesting feature of these analyses is that the typical markers for microbial transformation of sterols such as sterenes, stanones, or stanols, were not present within the limits of our detectability. Thus, we would conclude on the basis of this data set that the zooplankton and larger benthic organisms appear to be making the major contribution to the suspended particulate organic matter in the warm vent waters at 21 °N.

Further verification of both microbial and larger benthic organism contributions and analyses of other source markers will be needed to confirm these initial conclusions from the filtered vent water. Analyses of sediments, bacterial isolates[26], and larger organisms from 21° N are underway to ascertain more specifically the quantitative contributions of sources to the vent water organic matter.

We thank the NSF for support (OCE 80-24256) as part of the OASIS project. General support for the OASIS expedition was through NSF grant OCE 80-24895 to K. L. Smith. We gratefully acknowledge the assistance of expedition leader K. L. Smith, and R. Baldwin, G. Niles, and chief scientist of RV *New Horizon*, G. Somero. We also thank K. Doherty and H. Jannasch for design and construction of the *in situ* pumps; G. Nigrelli, K. Doherty, D. Nelson, and C. Wirsen for assistance with collecting samples; S. Wakeham, E. Peltzer, N. Frew and K. Robertson for analytical assistance; R. Hessler for communicating results before publication; and the captains and crews of the RV *New Horizon*, RV *Lulu*, DSRV *Alvin*, and RV *Melville*. J. Farrington, C. Lee, S. Wakeham, E. Peltzer, and C. Taylor made constructive comments to the manuscript. Experimental manipulation of a contact guidance system in amphibian gastrulation by mechanical tension

Norio Nakatsuji* & Kurt E. Johnson

Department of Anatomy, The George Washington University Medical Center, Washington DC, 20037, USA

Contact guidance[1,2] has been implied in various morphogenetic movements including neural crest cell migration[3], primordial germ cell migration[4] and guidance of axonal growth cone[5]. In urodele gastrulae, we reported[6] the presence of an aligned network of extracellular fibrils on the inside of the ectodermal layer and suggested that it guides the migration of the presumptive mesodermal cells from the blastopore towards the animal pole. We also reported[7] *in vitro* experiments in which the fibril network of the ectodermal layer was transferred onto the surface of a coverslip. Dissociated mesodermal cells attach to and locomote actively on such conditioned surfaces in an oriented fashion along the blastopore–animal pole axis (bp–ap axis) of the ectodermal layer that conditioned the surface. Recent reports[8,18] suggest that these fibrils contain fibronectin. We now report that the fibril network on the conditioned surface can be artificially aligned in any orientation by exerting mechanical tension on the ectodermal layer during the conditioning. Such prepared surfaces cause cell movements aligned along the tension axis, even when the tension axis is perpendicular to the natural axis of alignment along the bp–ap axis. These results suggest that the extracellular matrix fibrils aligned by the mechanical stress that arises in embryos during development can orient cell migration by the contact guidance, in a similar manner to that reported in the collagen gel and fibroblasts system[9,10].

We used *Ambystoma maculatum* eggs collected in North Carolina and Virginia. Developmental stages were determined according to Harrison stages[11]. Stage 10– represents very early gastrulae in which the mesodermal cells have not yet started their migration away from the blastopore. In more advanced early gastrulae (stage 10), cell migration is under way. Our previous study[7] showed that conditioning by stage 10 ectodermal layer causes substantial alignment of mesodermal cell movement, while the conditioning by a stage 10– ectodermal layer

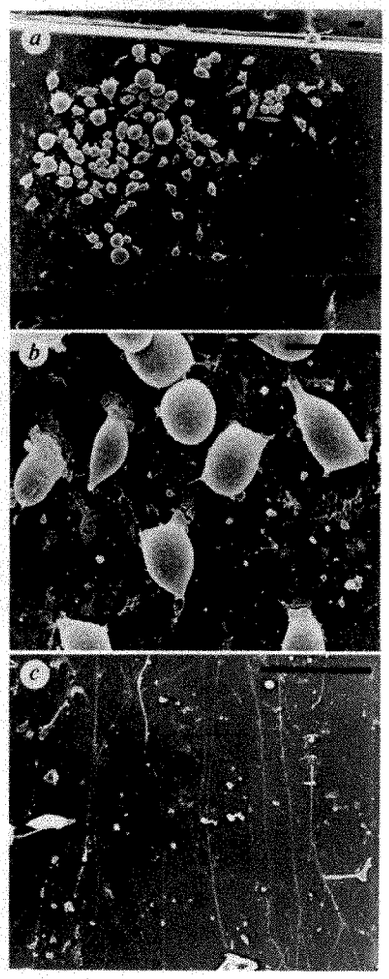

Fig. 1 Scanning electron micrographs of mesodermal cells attached to the conditioned coverslip strip. *a*, A low magnification view. Scale bar, 0.1 mm. *b*, Central part of *a* at higher magnification. Scale bar, 100 μm. *c*, Extracellular fibrils deposited on the coverslip surface. They are apparently aligned along the axis of tension (vertical axis). Scale bar, 10 μm. Strips were cut out from plastic coverslips for tissue culture (Thermanox coverslips, Miles) with a sharp steel blade. The composition of media used in this study is the same as used in the previous conditioning experiments[7]. The basic salt solution is a modified Stearns' solution (MSS)[15,16] buffered with 5 mM HEPES (Sigma). Mesodermal cells were dissociated in 0.02 M sodium citrate[17] in MSS lacking Ca^{2+} and Mg^{2+}. For conditioning of substrata with explants of the ectodermal layer, we used MSS with a *p*H of 8.0, a Ca^{2+} concentration of 110 μM, and containing 0.5% bovine serum albumin (BSA) (Sigma). This Ca^{2+} concentration is just high enough to prevent tissue dissociation and yet low enough to prevent curling of the ectodermal fragments, thus it allows the ectodermal fragments to adhere to the substratum and remain flat. The dissociated mesodermal cells were cultured in MSS *p*H 8.0, a Ca^{2+} concentration of 100 μM, and containing 0.5% BSA, which we have found to be optimal for cell locomotion.

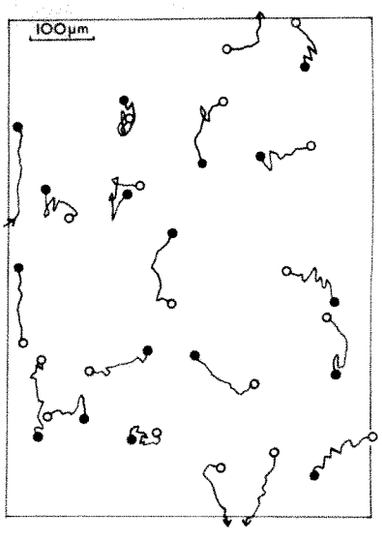

Fig. 2 Cell trails drawn from a time-lapse film of the tilted conditioning. ○, Starting points; ●, finishing points after 1 h. They are apparently aligned along the axis of tension (vertical axis). The overall *R* value calculated for all the cell trails here is +0.47. Time-lapse 16-mm films were taken with ×10 phase contrast lens at 8-s intervals. At the end of filming, the coverslip was fixed and processed for scanning electron microscopy[7]. We drew cell trails by projecting the time-lapse films and marking the centre of cell body at 4-min intervals[15].

gives only very weak alignment. This difference may be caused by the alignment of the fibril network by the expansion and stretching of the ectodermal layer along the bp–ap axis during gastrulation[12].

Rectangular pieces of the ectodermal cell layer were cut out from the whole blastocoelic roof of early gastrulae (stage 10−, or 10) using fine forceps and hair loops. The pieces were explanted on the coverslip strips (2 mm × 10 mm), which were set on top of two small fragments of glass capillary (outer diameter, 2 mm) like a bridge, so that the explant could be hung with both ends drooping free from the edges of the strip, thus producing constant mechanical tension perpendicular to the longer axis of the strip of coverslip. The inner surface of the ectodermal layer adhered to the coverslip surface. The strip of coverslip had been set horizontally or tilted by approximately 30° by applying a small amount of Vaseline between the glass capillary and the strip. The tilting allowed the mechanical tension to be maintained throughout the explant during the conditioning. In the horizontal setting, both edges of the coverslip held the ectodermal layer tightly and prevented the tension from transmitting to the central part of the explant. On the other hand, with tilting, there was one free edge so that the tension and stretching generated by the weight of the explant could be transmitted across the entire sheet. Explants from stage 10 embryos were placed on the coverslip with their bp–ap axis parallel to the longer axis of the strip. Explants from stage 10− embryos were oriented randomly, because they have not yet developed their natural alignment along the bp–ap axis[7].

After 5 h of culture at room temperature (22–24 °C), explants were removed from the coverslip by flushing them away with a Pasteur pipette. The coverslip strips were rinsed with culture medium, and placed horizontally in a plastic Petri dish. They were seeded with dissociated mesodermal cells from middle gastrulae (stage 10+) using a Pasteur pipette. The cells attach to the conditioned surface and start to migrate actively within 30 min. The mesodermal cells show no attachment outside the conditioned area. Figure 1*a* shows a low magnification view of a coverslip strip and attached cells. The cells frequently have a leading end with a large lamellipodium and associated filopodia and a slender or rounded trailing end (Fig. 1*b*). The conditioned surface is covered with fragments of cell-surface structures such as filopodia and a network of extracellular fibrils that can be observed only at higher magnifications (Fig. 1*c*). The network was apparently aligned along the axis of tension (Fig. 1*c*). In fact, when scanning electron micrographs of 10 randomly selected areas from the tilted conditioning were analysed by the microcomputer system (see below), they gave positive *R* values; mean and standard deviation were $+0.74 \pm 0.52$.

Cell trails from the tilted conditioning showed an apparent alignment along the axis of tension (Fig. 2). No alignment was noticeable when we used the horizontal conditioning. We further analysed the cell trails by using an image-analysing system with a microcomputer (Apple II Plus Computer and Graphics Tablet)[7]. The computer programs[7] we used enable us to determine

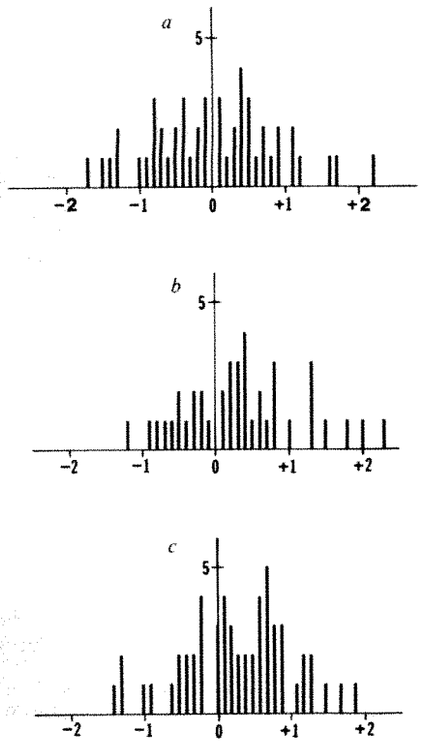

Fig. 3 Histograms showing distribution of cell trails according to their R values. Horizontal axis, R value; vertical axis, number of cell trails. *a*, Data from the horizontal conditioning, showing nearly normal distribution centred at zero (mean −0.01 and s.d. ±0.90, 52 cells). *b*, Tilted conditioning using the stage 10− ectodermal layer. The distribution is clearly shifted to the right (mean +0.36, s.d. ±0.78, 40 cells). The shift of mean is significant ($P < 0.005$). *c*, Tilted conditioning using the stage 10 ectodermal layer. The shift to the right (mean +0.29, s.d. ±0.73, 55 cells) is significant ($P < 0.005$).

whether the cell trails are aligned along the axis of the mechanical tension during the conditioning. Also, they were used to analyse alignment of the fibril network deposited on the conditioned surface. The programs calculate displacement (Δy and Δx) along the y-axis (axis of tension) and along the perpendicular x-axis in each short segment of the cell trail, and give sums of $|\Delta y|$ and $|\Delta x|$ separately for the whole cell trail. Then, it gives R values, $R = \log_2(\Sigma|\Delta y|/\Sigma|\Delta x|)$, as a parameter of the alignment; a zero value for non-aligned random movement, positive values of R for movement aligned along the axis of tension, and negative values for movement aligned perpendicular to the axis of tension. Figure 3 shows histograms of the distribution of cell trails according to their R values. When horizontal conditioning was used (Fig. 3*a*) we observed nearly normal distribution centred at zero, showing that the cell trails are not aligned. On the other hand, when we used tilted conditioning (Fig. 3*b*, *c*) we observed a distribution that was shifted to the right (positive values). The shift of the mean (+0.36 and +0.29) is larger than that of the natural alignment along the bp–ap axis in the stage 10 ectoderm conditioning (+0.22)[7]. Substratum conditioning using stage 10− ectodermal layers (Fig. 3*b*) gives stronger alignment than that using stage 10 ectoderm (Fig. 3*c*). The most likely explanation for this is that the stage 10 explant was oriented on the coverslip strip in such a way that its natural alignment along the bp–ap axis must be cancelled before any appearance of the alignment along the axis of tension.

Contact inhibition of cell movement is another mechanism that can direct cell migration from the blastopore with a high population of migratory cells towards the animal pole where the fibril network on the inner surface of the ectodermal layer offers an adequate substratum for cell attachment and locomotion. This possibility has been suggested[6,7,13,14], and the gastrula mesodermal cells indeed show contact paralysis against each other when cultured *in vitro*[13,15].

Forskolin activation of adenylate cyclase *in vivo* stimulates nerve regeneration

Suzanne L. Kilmer & Richard C. Carlsen

Department of Human Physiology, School of Medicine, University of California, Davis, California 95616, USA

The previous demonstration of an increase and redistribution of adenylate cyclase activity in injured peripheral nerve[1] suggests that an increase in neuronal cyclic AMP concentration could play a role in peripheral nerve regeneration. We report our finding that accumulating adenylate cyclase activity was translated into a twofold increase in cyclic AMP concentration in the regenerating nerve stump, coincident with the initiation and elongation of regenerative nerve sprouts. We sought to magnify the role of cyclic AMP in regeneration by using forskolin, a robust activator of adenylate cyclase[2], to produce an additional increase in neuronal cyclic AMP *in situ*. Forskolin *in vitro* produced an approximately 40-fold greater elevation in neuronal cyclic AMP than an equimolar (10^{-5}) concentration of isoprenaline. Moreover, the elevated cyclic AMP concentration persisted for at least 60 min in the continued presence of forskolin. Daily injection of forskolin into the dorsal lymph sac of *Rana pipiens*, or delivery of forskolin through an implanted osmotic pump produced a sustained 40% increase in the rate of sensory nerve regeneration in freeze-lesioned sciatic nerves. We conclude that an increase in cyclic AMP concentration and, presumably, the activation of appropriate protein kinases stimulates regenerative nerve growth following trauma.

Adenylate cyclase, the enzyme responsible for catalysing the formation of cyclic AMP from ATP, undergoes anterograde, but not retrograde axonal transport in normal frog sciatic nerve. If the nerve is subjected to crush or transection, however, adenylate cyclase activity accumulates proximal to the site of injury and is incorporated in the retrograde transport system for return toward the cell body[1]. While these observations provide the basis for a stimulated production of cyclic AMP in regenerating nerve, increased production does not necessarily lead to increased concentration. A parallel elevation of phosphodiesterase activity, an enzyme which also undergoes axonal transport[3], could prevent accumulation of the cyclic nucleotide. We measured cyclic AMP concentration in specific regions of axotomized frog sciatic nerve at 2, 4 and 7 days after a freeze-

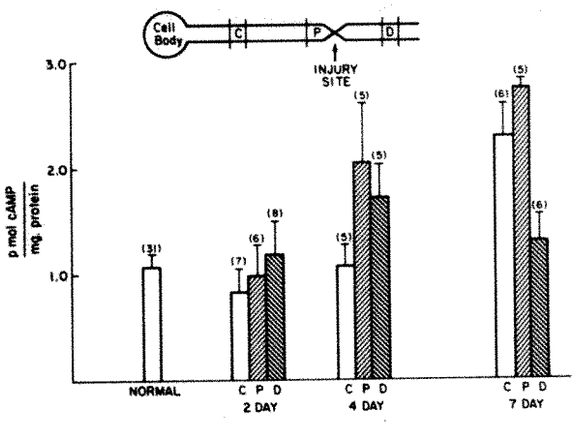

Fig. 1 The concentration of cyclic AMP in 3–4 mm desheathed nerve segments removed from indicated regions of normal and freeze-lesioned sciatic nerves at specified times following the injury. Numbers in parentheses represent the sample size for each measurement. Sample P was obtained just proximal to the injury and includes regenerative growth at 4 and 7 days. Samples C and D were removed from regions 1 cm proximal and 1 cm distal to the injury respectively.

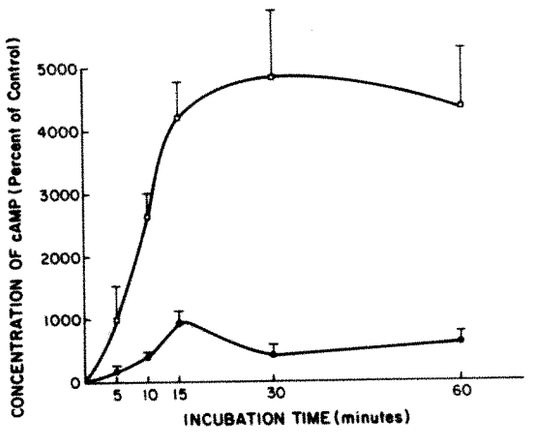

Fig. 2 Comparison of the relative stimulatory capabilities of equimolar concentrations (10^{-5} M) of forskolin (Calbiochem) (□) and isoprenaline (●) applied to desheathed 3–4 mm segments of normal sciatic nerve *in vitro*. Each time point represents the mean ± s.e.m. of four measurements. Nerve segments were preincubated for 1 h at room temperature in normal frog Ringer's solution through which a mixture 95% O_2:5% CO_2 was continuously bubbled. The preincubation solution was removed and fresh solution added for a second 15 min preincubation. The drug was then added for the specified period of time, at the end of which the nerve segment was frozen and cyclic AMP extracted for radioimmunoassay. Each stimulated segment was paired with an unstimulated control.

lesion of the nerve. These post-injury intervals were chosen to reflect the period prior to regenerative sprouting (2 days), the period of sprout initiation (4 days) and the early period of axon elongation (7 days). The results of these experiments are presented in Fig. 1. Freeze-lesioned or intact sciatic nerves were removed from northern *Rana pipiens* (30–50 g body weight, mixed sex, obtained from J. Hazen, Alburg, Vermont, USA, during Winter and Spring). The isolated nerve was placed in Ringer's solution and desheathed. Desheathed nerve segments, 3–4 mm in length, were obtained from the injury site (including regenerative sprouts) and from regions 1 cm proximal and 1 cm distal to the injury. Each segment was incubated in a separate flask containing Ringer's solution without a phosphodiesterase inhibitor for 1 h at room temperature (21–22 °C). The solution was continuously supplied with a mixture of 95% O_2 and 5% CO_2. At the end of the incubation period the segment was rapidly frozen in a mixture of ethanol:hydrochloric acid (60:1, wt/wt) cooled on dry ice (−70 °C). The frozen tissue was homogenized and prepared for analysis of cyclic AMP concentration by radioimmunoassay[4]. Protein concentration was determined using the Lowry assay. The mean concentration of cyclic AMP in segments from the selected locations were compared statistically to segments from similar regions of intact nerves using analysis of variance and Dunnett's *t*-test.

Cyclic AMP concentration was not significantly different from normal nerve in any of the three sample regions of axotomized nerve 2 days after injury. Thus, the early accumulation of adenylate cyclase activity at the injury site[1] was not translated into an equivalent increase in cyclic AMP concentration prior to the development of regenerative sprouting. After 4 days, however, cyclic AMP concentration was significantly ($P < 0.05$) increased in the region of regenerative growth, when regenerative sprouts are first appearing[3]. Concentration also increased in segments distal to the injury at 4 days, although the increase was not statistically significant. At 7 days, cyclic AMP concentration was significantly increased in nerve segments encompassing regenerative growth, and in segments 1 cm proximal to the injury ($P < 0.01$). Concentration in segments distal to the injury had returned to control values.

This pattern of change in cyclic AMP concentration supports our hypothesis that an increase in cyclic AMP concentration may play an integral role in nerve regeneration. Previous studies, however, in which dibutyryl cyclic AMP was injected into rats during the course of peripheral nerve regeneration offer mixed results[6–9]. The treatment-enhanced regeneration in two cases[6,7], but had no effect in two others[8,9]. None of these studies assessed the actual cyclic AMP concentration in the regenerating nerve, or the magnitude of the presumed increase resulting from the injection of dibutyryl cyclic AMP. We chose to explore the possible role of cyclic AMP in regeneration by using an extremely potent activator of adenylate cyclase, forskolin (Calbiochem), to increase endogenous levels of cyclic AMP in the injured nerve. Forskolin stimulates adenylate cyclase via the catalytic subunit of the enzyme[2], and produced an increase in activity two to three times that produced by sodium fluoride in frog nerve (unpublished observation). Incubation of desheathed nerve segments from normal frog nerve in media containing either 10^{-5} M forskolin or 10^{-5} M isoprenaline demonstrated that forskolin could produce an increase in cyclic AMP concentration 40-fold greater than that produced by isoprenaline (Fig. 2). Moreover, the increase in concentration was sustained for at least 60 min in the continued presence of forskolin.

The effect of forskolin on nerve regeneration was tested in frogs subjected to a unilateral freeze-lesion of the sciatic nerve at mid-thigh. Forskolin was provided either by daily injection of 0.5 ml of a 5×10^{-4} M solution into the dorsal lymph sac, or by implanting an osmotic pump (Alza) which delivered 0.55 μl per h (21 °C) of a 10^{-4} M solution in the vicinity of the injury. Animals with an implanted pump also received a single 'priming' injection of the 5×10^{-4} M forskolin solution (0.5 ml). Control animals received daily saline injections or had implanted osmotic pumps containing a 0.64% saline solution. Regeneration distance in both forskolin-treated and control animals was determined using axonal transport of H^3-leucine-labelled protein from lumbar dorsal root ganglia to determine the maximum extent of sensory nerve outgrowth[5,10]. Ganglia and attached spinal and sciatic nerves were removed and placed in a compartmented chamber[11]. The ganglia were contained in a centre compartment and the nerves passed through a silicone grease barrier into an outer compartment. The tissue was bathed in aerated Ringer's solution and 50 μCi ml^{-1} of ^{3}H-leucine added to the ganglia compartment. Following a 3–4 h incubation period the isotope was removed, the tissue washed and placed in a second chamber; axonal transport was then allowed to continue for an additional 16–18 h. At the end of the transport period the nerve was frozen and divided into 1- or 2-mm segments. Each segment was placed in 5% trichloroacetic acid (TCA)

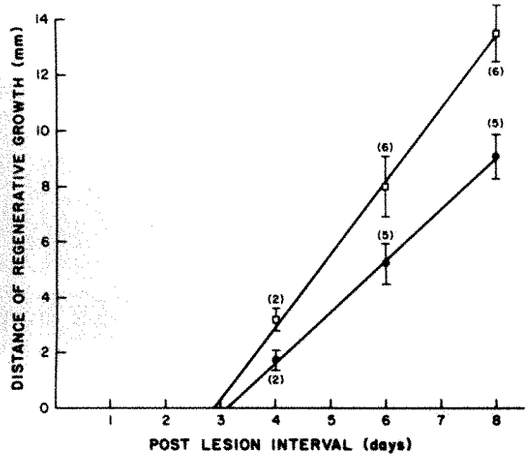

Fig. 3 Measurement of regeneration distance in axotomized sensory nerves from animals receiving forskolin and from saline-treated controls. Regeneration distance was determined at the indicated time points by assaying the distribution of axonally-transported radioactively labelled protein in the regenerating nerves. Distances at each time point represent the mean ± s.d. of the indicated number of measurements. Distance points were connected by linear regression lines using the method of least squares. The slope of each line indicates the regeneration rate in forskolin-treated and control, saline-treated sensory nerves. For treated nerves the slope is 2.6 mm per day, and for controls, 1.86 mm per day.

overnight to separate TCA-soluble and insoluble material. The soluble material was discarded and the amount of TCA-insoluble radioactivity determined by liquid scintillation spectroscopy. Regeneration distance was taken as the point at which sample counts declined to within two standard deviations of mean background activity[10]. Forskolin-treated frogs showed a 40% increase in the rate of sensory nerve regeneration without a statistically significant change in latency to the initiation of regenerative growth. Enhancement of regenerative growth was the same using either of the two modes of drug application (results are pooled in Fig. 3). Regeneration rate in forskolin-treated nerves was significantly greater ($P < 0.001$) than the rate in saline-treated animals, as determined by linear regression analysis[12]. Forskolin-stimulated enhancement of regeneration also exceeded the 12–17 percent enhancement obtained using the condition/test paradigm[9] in frogs at 25 °C[12].

Functional recovery following nerve injury requires both axonal regrowth and reconnection with appropriate target organs. The processes responsible for recovery are complex and require interaction between the injured axon, its cell body, periaxonal cells in the axon and, eventually, cells in the target organ[13]. In the present experiments we attempted to link an increase in cyclic AMP concentration in regenerating axons to the development of regenerative growth. We determined that forskolin, an agent which stimulates cyclic AMP production also enhances the rate of axon regeneration. The site of action of forskolin is currently unknown, but could involve processes in either or both the axonal injury site or the nerve cell body. Forskolin does not cross the blood–brain barrier[2], but dorsal root ganglia neurones are not contained within the barrier[14] and injected forskolin should be able to interact with injured sensory cell bodies. The role of cyclic AMP in regeneration is also unknown, although an increase in cyclic AMP might stimulate microtubule aggregation to enhance sprout formation[15] or provide a modulating influence on RNA and protein synthesis in the cell body[16]. While the rate of nerve regeneration is but one aspect of the recovery process, stimulation of rate, particularly in human nerve injuries located far proximal in a limb, might improve recovery by allowing re-innervation of target tissue before target organ degeneration has become extensive[17]. We are currently investigating the specific molecular role of cyclic AMP in injured nerve, but it appears clear that the nucleotide can play an important role in axonal growth.

Acceptors for botulinum neurotoxin reside on motor nerve terminals and mediate its internalization

J. Oliver Dolly*, Jennifer Black*, Richard S. Williams* & Jack Melling†

* Department of Biochemistry, Imperial College, London SW7 2AZ, UK

Botulinum neurotoxin (BoNY) type A, a causative agent of botulism, is a di-chain protein (molecular weight 140,000) from *Clostridium botulinum*, and the most neurotoxic substance known[1]. Some cases of sudden infant cot deaths have been attributed to such a neuroparalytic condition[2]. BoNT inhibits irreversibly the release of acetylcholine from peripheral nerves in a highly selective manner[3–6]. Hence, it is potentially an invaluable probe for studying the mechanism of transmitter release[7,8]. Here we demonstrate specific labelling of murine motor nerve terminals with neurotoxic, ^{125}I-labelled BoNT (type A) by autoradiography. We observed saturable, temperature-sensitive binding of BoNT to sites which reside solely on the nerve terminal membrane; these were distributed on all unmyelinated areas, at an average density of 150–500 per μm^2 of membrane. The binding was mediated by the larger subunit of the toxin and was inhibited partially by tetanus toxin, another microbial protein[9]. No specific binding was detectable on any other cell types examined, including noradrenergic terminals. Following binding, internalization of radioactivity was observed; this process was energy-dependent as it could be prevented totally by azide or dinitrophenol (DNP). This direct demonstration of separable steps, including highly selective binding and acceptor-mediated internalization, is reconcilable with the unique potency and the multiphasic inhibitory action of BoNT on transmitter release, as shown electrophysiologically[8].

To facilitate characterization of BoNT-binding sites on neuronal membranes, with the long-term goal of elucidating the molecular basis of its action, BoNT type A was purified to homogeneity and ^{125}I-iodinated to high specific radioactivity (700–3,000 Ci mmol^{-1}). The resultant BoNT (^{125}I-BoNT) retained appreciable levels of neurotoxicity (60–85% of the original, equivalent to 2×10^8 mouse lethal doses per mg protein)[7,10] and was shown to bind saturably and with high affinity to a sialic acid-containing moiety on brain synaptic membranes[10]. Additional evidence of its biological activity was provided by the demonstration, using light microscope autoradiography, that it binds at low concentrations to a discrete

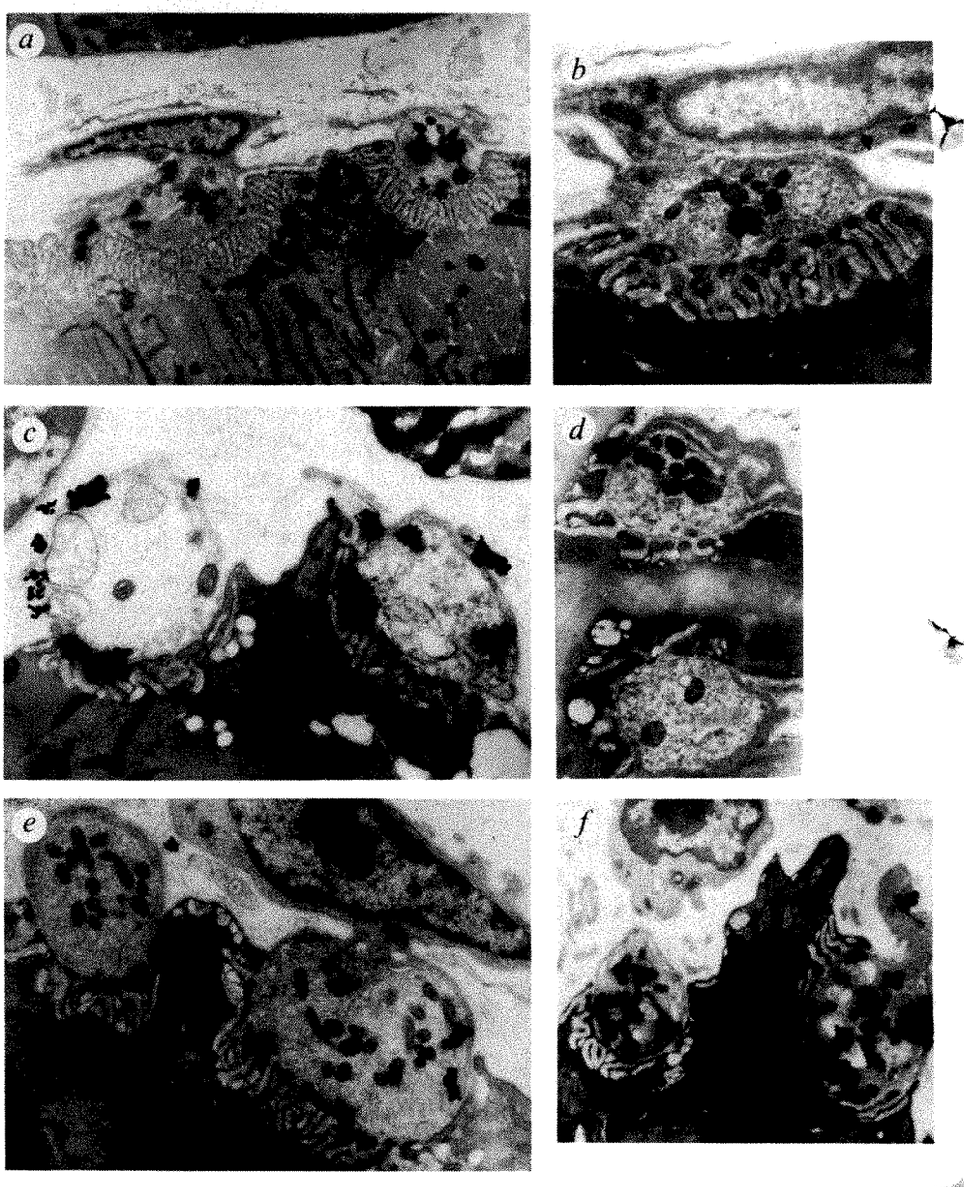

Fig. 1 Electron microscope autoradiograms of phrenic nerve muscle preparations labelled with ^{125}I-BoNT. *a*, *c*, *e*, With tetanus toxin; *b*, *d*, *f*, without. *a*, Sample treated with ^{125}I-BoNT alone. *b*, Control sample labelled with ^{125}I-BoNT and excess unlabelled toxin. *c*, Muscle preincubated at 22 °C for 20 min in Krebs–Ringer's containing 15 mM sodium azide and then labelled in the latter medium with ^{125}I-BoNT as in *a*. *d*, A control sample of tissue treated with sodium azide as in *c* then incubated with labelled and unlabelled BoNT as in *b*. *f*, Specimen labelled with ^{125}I-BoNT as in *a* except that the incubation period with toxin was 2 h. *e*, The preparation was preincubated with 0.9 μM tetanus toxin; ^{125}I-BoNT was then added and the incubation continued for a further 2 h.

Methods: Each dissected mouse hemidiaphragm was incubated with 11 nM ^{125}I-BoNT in 0.5 ml Krebs–Ringer's *p*H 7.4 at 22 °C for 1.5 h unless otherwise specified; use of a 3 ml incubation volume yielded similar results. Control samples were treated similarly except that 1.1 μM BoNT was added together with the radiolabelled toxin. Labelled tissues were washed repeatedly in Krebs–Ringer's for 30 min at 22 °C before fixation for 1 h with 2% glutaraldehyde in the latter solution. Endplate-containing regions of each sample were cut into 1-mm^3 pieces, treated with 1% OsO_4 for 1 h, dehydrated in ethanol and embedded in Spurr's resin. Pale gold or silver sections were cut using an LKB ultramicrotome and processed for autoradiography[13]; a monolayer of L4 emulsion was applied to the sample by dipping. Sections were exposed for 3 weeks, developed in Kodak D-19 developer, stained with 12% uranyl acetate, examined in a Hitachi electron microscope and photographed.

Table 1 Autoradiographic analysis of nerve terminals labelled with ^{125}I-BoNT

Incubations	Distribution of grains with respect to the plasma membrane (% of total)		Relative number of grains/unit area of plasma membrane (%)
	On*	Within	
Series I (28 nM ^{125}I-BoNT)			
No additives	62 (±16; $n = 15$)	38 (±16; $n = 15$)	100†
1.4 μM BoNT	—	—	4
$-Ca^{2+}/+2$ mM EGTA	61 (±24; $n = 21$)	39 (±24; $n = 21$)	74
Series II (11 nM ^{125}I-BoNT)			
No additives	61 (±17; $n = 22$)	39 (±17; $n = 22$)	100†
1.1 μM BoNT	—	—	5
0.5 μM BoNT large subunit	—	—	0
15 mM sodium azide	100 ($n = 50$)	—	85
0.9 μM tetanus toxin	61 (±25; $n = 23$)	39 (±25; $n = 23$)	31
Series III (1 nM ^{125}I-BoNT)			
No additives	54 (±24; $n = 6$)	46 (±24; $n = 6$)	100†
50 nM BoNT	—	—	0

Mouse hemidiaphragms were labelled with ^{125}I-BoNT for 1.5 h at 22 °C in 0.5 ml of Krebs–Ringer's solution in the conditions specified. Tissues were subsequently washed, fixed, embedded and pale gold sections were cut; autoradiograms of these were prepared and developed after 3 weeks' exposure, as detailed in Fig. 1. After examination in a Hitachi electron microscope, large numbers of nerve endings in several sections were photographed; the silver grains in each were counted and the mean values (±s.d., n = number of terminals counted) are expressed. The samples in each series of experiments were treated identically.

* 90% of these grains were found on the membrane itself; 10% were within 150 nm of the latter and can be attributed to expected scatter.

† The area of the terminal membrane in each section was calculated by digitization and the total number of grains observed on the membrane and enclosed within it were expressed per unit area of the membrane; these were taken to represent 100% in each case.

number of sites at murine motor endplates[7,11], following *in vivo* or *in vitro* labelling; a similar observation has been made for another preparation of ^{125}I-BoNT[12].

To locate the site of this binding, mouse hemidiaphragms were incubated with ^{125}I-BoNT, washed and processed for autoradiography[13] before examination by electron microscopy. To measure nonspecific binding of ^{125}I-BoNT, samples were treated similarly except that an excess of BoNT was included. After labelling of nerve–muscle preparations with ^{125}I-BoNT *in vitro*, in conditions which block neurotransmission[5], autoradiography showed a distinct deposition of silver grains at the motor nerve endings (Fig. 1*a*). This labelling was saturable as control samples treated with excess BoNT contained few, if any, silver grains (Fig. 1*b*; Table 1). All the sites were occupied when 50 nM ^{125}I-BoNT was used, in labelling conditions (1.5 h; 22 °C) that minimize structural damage to the tissue. Greatly reduced numbers of grains were seen when the incubation was done at 4 °C; we have been unable to ascertain how much changes in rate of diffusion contribute to this.

A similar qualitative deposition of grains was observed when low amounts (0.5 nM) of ^{125}I-BoNT were used, although fewer grains were apparent. This does not preclude the possibility that the acceptors have a high affinity for BoNT, as even higher concentrations (~1 μM) of α-bungarotoxin ($K_D \sim 10^{-11}$ M) are similarly required to overcome diffusion barriers in this tissue[14], within a similar incubation period. In all cases, the labelling with ^{125}I-BoNT was associated selectively with nerve terminals. Muscle, blood vessels, connective tissue, Schwann cells and myelin were virtually devoid of grains (Fig. 1); the number of grains observed was insignificant and these were distributed randomly, their presence being unaffected by excess unlabelled BoNT. Furthermore, it proved impossible to demonstrate any deposition of silver grains on noradrenergic terminals (Fig. 2) of mouse vas deferens[15], despite use of high ^{125}I-BoNT concentrations.

The saturable labelling of nerve terminals demonstrated with ^{125}I-BoNT was restricted to the presynaptic membrane (Fig. 1, Table 1); using the standard incubation conditions, most grains (62 ± 16% of the total) were located on the nerve membrane, the remainder being inside the terminal. Transfer of radioactivity across the plasma membrane was detectable after incubation with 11 nM toxin for 20 min, but the extent of internalization reached a maximum after 90 min; at present, we do not know whether the grains seen represent the intact toxin molecule or one of its subunits. However, when a homogeneous preparation of the non-toxic larger subunit of BoNT was included in the incubation medium, after separation[10] and renaturation (neurotoxic material can be reconstituted by the addition of the smaller subunit [55,000 molecular weight] to this preparation[16]), there was no ^{125}I-BoNT labelling (Table 1). This showed that the heavier subunit (97,000 molecular weight) is responsible for the observed binding, as is the case for binding to brain synaptosomal membranes[10]. The kinetics of the toxin's neuroparalytic action are consistent with the involvement of a target site within the terminal[17] and the findings presented here provide the first direct evidence for such internalization of BoNT. Lowering the temperature to 4 °C abolished internalization of radioactivity, as did inhibitors of energy production such as azide (Fig. 1*c*, Table 1) or DNP. This indicates that the overall process is energy requiring; we do not know which of the many possible mechanisms[18] is involved. In these conditions the labelling was saturable (Fig. 1*c* and *d*); although the total number of grains observed was reduced somewhat, they were now all deposited on the neuronal membrane (Table 1) or, at least, very close to it. Tetanus toxin was tested as a possible antagonist for the BoNT acceptor since its structure[8] is comparable and it has a related pharmacological action[9,19]. The labelling of nerve terminals was reduced significantly in the presence of tetanus toxin (Fig. 1*e* and *f*); however, the fraction of radioactivity internalized was unaffected (Table 1). Thus, the inhibitory action of tetanus toxin, together with that of the large BoNT subunit, on the labelling observed further supports the saturability of the BoNT acceptor. Collectively, the findings demonstrate the existence of at least two distinguishable and sequential steps—toxin binding and internalization.

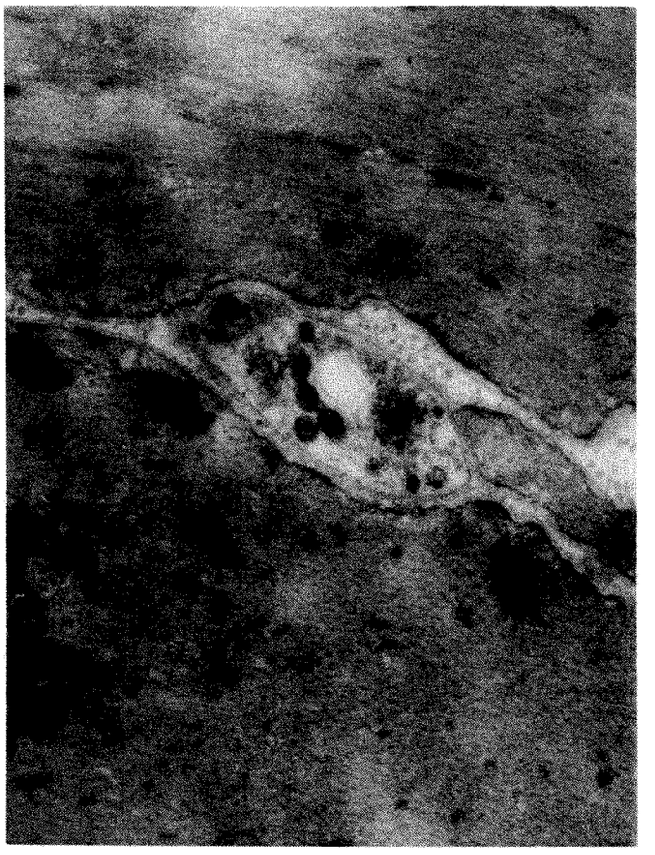

Fig. 2 Autoradiography of noradrenergic terminals from mouse vas deferens treated with ^{125}I-BoNT. The serosal coat of the dissected vas deferens was removed by gentle pulling and the remaining tissue incubated with 22 nM ^{125}I-BoNT in 0.5 ml Krebs–Ringer's for 90 min at 22 °C. The tissue was washed with Krebs–Ringer's for 30 min, then it was stretched and held in place with pins before being fixed for 90 min at 22 °C with 3% glutaraldehyde/2% paraformaldehyde/0.1 M sodium cacodylate buffer, *p*H 7.4. The sample was cut transversely into small segments and these were washed twice for 20 min in 5% sucrose/0.1 M sodium cacodylate buffer, *p*H 7.4 before treatment for 1 h at 22 °C with 2% OsO_4 in the latter buffer. This fixation method yields maximum preservation of dense core vesicles which facilitate identification of the noradrenergic terminals. After washing, the sample was dehydrated, embedded and prepared for autoradiography as described in Fig. 1 legend. The sections were developed after 3 weeks' exposure, viewed in the electron microscope and photographed. Dense core vesicles, which are characteristic of noradrenergic nerve terminals, were observed but no silver grains were seen in any area of the sections.

With toxin uptake inhibited, the content of binding sites could be quantified readily; using an established procedure[13], the average density was calculated to be 150–500 sites per μm^2 of membrane. Also, with azide present it was apparent that the binding sites are distributed uniformly over all the unmyelinated areas of the terminal membrane (Fig. 1*c*). Hence, in contrast to previous suggestions[20], it appears unlikely that the binding sites are involved directly in the process of transmitter release because their location is not restricted to the areas of membrane (active zones) opposing the postsynaptic folds, where release is thought to occur. It should be emphasized that with a low concentration of ^{125}I-BoNT (1 nM), in the presence of azide, the grain distribution obtained was similar; in fact, examination of autoradiograms of 21 endplates labelled in this manner showed that in 16, grains were not restricted to the active zone regions (as was seen also with higher toxin concentrations). Nevertheless, the apparent selective location (Figs 1 and 2) of

the binding site on cholinergic nerve membranes (at least in the periphery) indicates some, as yet unidentified, role. At least it seems clear from the de-energization experiments (Fig. 1*c*, Table 1) that the binding step is essential for translocation of the toxin into the nerve terminal. Furthermore, in the case of noradrenergic synapses[6] where BoNT is unable to inhibit neurotransmission at concentrations known to inhibit acetylcholine release at motor nerve terminals[21], the demonstrable absence of any binding sites for BoNT could render the transport of toxin across the plasma membrane to its site of action impossible. The minimal inhibitory effects on noradrenergic transmission in the anococcygeus muscle, seen after application of BoNT for long periods[6], may result from its inefficient uptake by another route. Similarly, absence of the toxin acceptor could explain why non-adrenergic, non-cholinergic transmission in guinea pig taenia coli is unaffected by BoNT[6]. It is likely that the intraterminal target may be common to several synapse types. Finally, the ability of tetanus toxin to antagonize BoNT binding emphasizes the importance of the toxin-binding step, as there are many similarities in the actions of these toxins at motor endplates[19].

Although all available pharmacological data[8] and the findings reported here support the contention that toxin translocation is essential for its neurotoxicity, additional evidence was sought using conditions known to interfere with the neuroparalytic action of BoNT, without perturbing its binding. In contrast to deductions from electrophysiological investigations[17], absence of Ca^{2+} from the incubation medium did not appreciably inhibit the internalization (or binding) of BoNT (Table 1). Similarly, lysosomotrophic agents (for example, chloroquine) which are effective antagonists of botulism[21] failed to prevent BoNT translocation (data not shown). Chloroquine is known to retard the expression of the activity of other microbial toxins[22], following their internalization by energy-dependent process(es) of the type described here. Thus, it is likely that this ability (which involves increasing the *p*H of lysosomes[22] or possibly of other compartments[23]), rather than its proposed effectiveness in inhibiting uptake[21], is implicated in delaying the onset of neuroparalysis by BoNT. With regard to the individual steps of botulinization, the resolution of autoradiographic techniques cannot exclude membrane sequestration of toxin following its binding to external sites. However, it is not likely that this could allow direct access of toxin to its pharmacological target because of the demonstrated internalization of toxin and its sensitivity to chloroquine. Thus, intoxication seems to depend on toxin uptake; the associated intraterminal events could facilitate a detrimental interaction of BoNT, or a fragment of it, with a component essential for transmitter release. This final target might reside within the active zones; in fact, it could be responsible for the presence of some silver grains in autoradiograms of terminals labelled with ^{125}I-BoNT in the absence of azide (Fig. 1*a* and *f*).

L-Glutamate has higher affinity than other amino acids for [^{3}H]-D-AP5 binding sites in rat brain membranes

H. J. Olverman, A. W. Jones & J. C. Watkins

Department of Pharmacology, The Medical School, University Walk, Bristol BS8 1TD, UK

Electrophysiological studies indicate the existence of several types of receptors for excitatory amino acids[1]. Thus, responses induced by *N*-methyl-D-aspartate (NMDA) are potently and selectively blocked by D(−)-2-amino-5-phosphonopentanoic acid (D-AP5), while responses induced by such agonists as kainate and quisqualate are relatively resistant to this antagonist[2,3]. Evidence is mounting that excitatory amino acid receptors are involved in synaptic excitation in many regions of the central nervous system (see refs 1 and 4 for reviews). Although the identity of the transmitter(s) acting at these receptors remains uncertain[5], L-aspartate has been considered the most likely transmitter at NMDA receptors and L-glutamate at kainate/quisqualate receptors[1,4]. Other endogenous acidic amino acids proposed as possible transmitters include a range of sulphur-containing amino acids[6] and the tryptophan metabolite, quinolinic acid[7]. Ligand-binding studies offer a means not only of assessing receptor densities in different brain regions but also of comparing affinities of transmitter candidates for these receptors. However, to avoid difficulties of interpretation arising from the use of ligands which bind to more than one type of receptor, such as [^{3}H]-L-glutamate and [^{3}H]-L-aspartate (for example, refs 8–12), ligands with high receptor selectivity are required. Here, we report that [^{3}H]-D-AP5 binds specifically to rat brain membranes, that the hippocampus and cerebral cortex are enriched in these sites relative to other brain areas and that L-glutamate has higher affinity for these receptors than have all other transmitter candidates tested.

[^{3}H]-D-AP5 binding to rat cerebral cortical membranes reached equilibrium following 20 min incubation at 25 °C. Specific binding contributed about 40% to the total binding at 30 nM [^{3}H]-D-AP5. This binding was reversible, the bound ligand being completely displaced by 1 mM unlabelled ligand added at 25 min with a $t_{1/2}$ of 5 min. The kinetics of D-AP5 binding were investigated by incubating membranes with 17 nM [^{3}H]-D-AP5 in the presence of increasing concentrations of unlabelled D-AP5 (0.05–100 μM); computer fitting of the data revealed a single population of receptors (Fig. 1). Analysis of results from four such experiments gave K_D and B_{max} values of 0.47 ± 0.09 μM and 4.1 ± 0.7 pmol per mg protein respectively (mean values ± s.e.). D-AP5 binding sites were present in all areas of the CNS tested. There was, however, a marked enrichment especially in the hippocampus, but also in the cerebral cortex (Fig. 2). Specific binding was lowest in the cerebellum and in the medulla/pons, where the density of sites was one quarter that observed in the hippocampus.

To determine if the binding sites for [^{3}H]-D-AP5 were identical with NMDA receptors characterized in electrophysiological studies, a number of excitatory amino acid antagonists of known pharmacological profile were tested as inhibitors of binding. Within an homologous series of ω-phosphono-α-aminocarboxylates[2], both (±)-AP3 and (±)-AP4, which are the ω-phosphono analogues of aspartate and glutamate respectively, were relatively ineffective as inhibitors of binding, whereas the longer chain analogue, (±)-AP7, was almost equipotent with (±)-AP5.

Table 1 Inhibition of [^{3}H]-D-AP5 binding to cortical membranes by excitatory amino acid agonists and antagonists

Antagonists	K_i (μM)
(±)-2-Amino-3-phosphonopropanoate (AP3)	560
(±)-2-Amino-4-phosphonobutanoate (AP4)	260
(±)-2-Amino-5-phosphonopentanoate (AP5)	1.7
(±)-2-Amino-6-phosphonohexanoate (AP6)	42
(±)-2-Amino-7-phosphonoheptanoate (AP7)	2.4
(±)-2-Amino-8-phosphono-octanoate (AP8)	640
D(−)-AP5	0.62
L(+)-AP5	55
γ-D-Glutamylglycine (γ-D-GG)	40
(±)-*cis*-2,3-Piperidine dicarboxylate (*cis*-2,3-PDA)	78
γ-D-Glutamylaminomethyl sulphonate (γ-D-GAMS)	770
Agonists	
NMDA	11
Quisqualate	250
Kainate	870
L-Aspartate	11
L-Cysteate	120
L-Cysteine sulphinate	13
L-Glutamate	0.9
L-Homocysteate	3.9
L-Homocysteine sulphinate	10
L-*S*-Sulphocysteine	2.1
Quinolinate	350
L-*O*-Sulphoserine	25
L-*O*-Phosphoserine	1,000

Membranes were incubated with [^{3}H]-D-AP5 (20 nM) as described in Fig. 1 in the presence of a range of concentrations of inhibitor (10 nM–1 mM). IC_{50} values were determined from log concentration/inhibition curves and K_i values calculated[16]. Results are mean values from two or three experiments.

The homologues (±)-AP6 and (±)-AP8 were of intermediate potency (Table 1). There was a close quantitative correlation between the potency of these compounds as inhibitors of [^{3}H]-D-AP5 binding and their potencies as antagonists of NMDA-induced depolarizations and of electrically evoked depolarizations in spinal cord preparations (Fig. 3). The effects of other amino acid antagonists on [^{3}H]-D-AP5 binding also paralleled their known potencies as NMDA antagonists[1–3]. Thus binding was stereoselective for the D-isomer[2,3], L(+)-AP5 being 80-fold weaker than D(−)-AP5. The slight activity of the L form may be due to incomplete resolution, consistent with the small difference in magnitude of the optical rotations of the two isomers. In addition, γ-D-GG and *cis*-2,3-PDA, which are less potent (and less selective) antagonists for NMDA receptors than are AP5 and AP7, were of intermediate potency. By contrast, γ-D-GAMS, which antagonizes neuronal depolarizations induced by kainate and quisqualate with little or no effect on NMDA-induced responses[13,14], was ineffective as an inhibitor of [^{3}H]-D-AP5 binding (Table 1). This strongly suggests that [^{3}H]-D-AP5 binds to the NMDA-type receptor identified in electrophysiological studies.

Depolarizations induced by agonists such as glutamate and aspartate are composite responses mediated by different types of receptors. This, coupled with other complications, such as differential rates of amino acid uptake, makes it difficult to compare relative potencies of agonists at particular excitatory receptors in electrophysiological studies. It was, therefore, of great interest to determine affinities of a range of agonists tested as inhibitors of [^{3}H]-D-AP5 binding to cerebral cortical membranes. Of the three amino acids normally considered to be selective receptor agonists, NMDA was the most potent being 25 and 80 times more potent than quisqualate and kainate, respectively. (The quisqualate activity may indeed be due to a trace of glutamate detected in our preparation by high-voltage paper electrophoresis.) The other agonists listed in Table 1 have all been found in brain and/or other body tissues or fluids and can thus be considered as possible neurotransmitters. Both

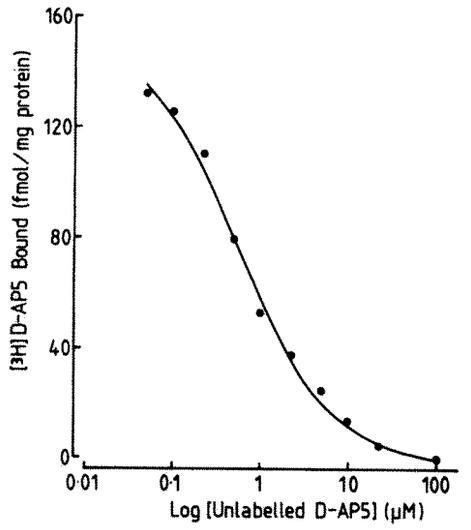

Fig. 1 Concentration dependence of [^{3}H]-D-AP5 binding to rat cerebral cortical membranes. Cerebral cortex from male Wistar rats was homogenized in 15 volumes ice-cold 0.32 M sucrose, *p*H 7, and the homogenate centrifuged at 1,000*g* for 10 min at 4 °C. The supernatant was recentrifuged (17,000*g*; 20 min) and the resultant P_2 pellet lysed with 40 volumes glass-distilled water (GDW). Following incubation at 35 °C for 30 min, the membranes were centrifuged at 50,000*g* for 10 min, then washed twice by resuspension in 40 volumes GDW and centrifugation (50,000*g*; 10 min). The final pellet was resuspended in 25 volumes 50 mM Tris-HCl buffer, *p*H 7.3. Binding of [^{3}H]-D-AP5 was measured by preincubating 0.4 ml aliquots of membrane suspension (0.3–0.5 mg protein) with 50 μl D-AP5 (final concentration 0.05–100 μM) or with buffer alone (control) for 3 min at 25 °C before addition of 50-μl [^{3}H]-D-AP5 (27.3 Ci mmol^{-1}; custom-labelled by Amersham International). Final concentration of [^{3}H]-ligand was 17 nM. Samples were centrifuged after 25-min incubation at 25 °C (20,000*g*; 1 min), the clear supernatant aspirated and the amount of radioactivity in the pellets measured by liquid scintillation counting (Packard Tricarb 460 CD). Specific binding of [^{3}H]-D-AP5 was determined by subtracting the nonspecific component (binding in the presence of 1 mM unlabelled D-AP5) from the total binding. Binding in control samples was 155 fmol per mg protein. Each point is the mean of three determinations. Protein was assayed as described by Lowry[17]. Results were fitted by least squares[18] to the logistic expression $Y = MX^p/(X^p + EC_{50}^p)$ and calculated values were *M*, 153 ± 9 fmol per mg protein; EC_{50}, 0.56 ± 0.11 μM and *P*, 0.9 ± 0.08.

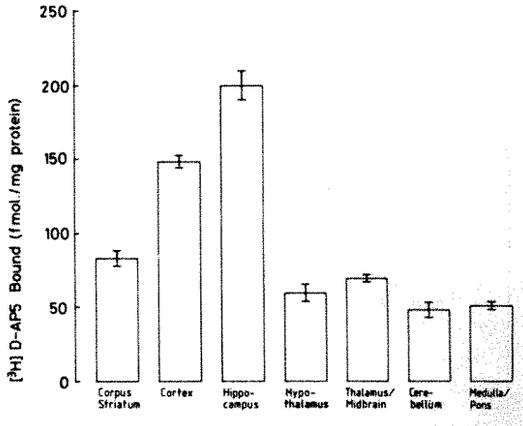

Fig. 2 Regional distribution of [^{3}H]-D-AP5 binding sites. Each brain area was carefully dissected as described by Glowinski and Iversen[20]. Membranes were prepared and specific binding of [^{3}H]-D-AP5 (16 nM) measured as in Fig. 1. Results are mean values ± s.e. ($n = 12$) from two separate experiments.

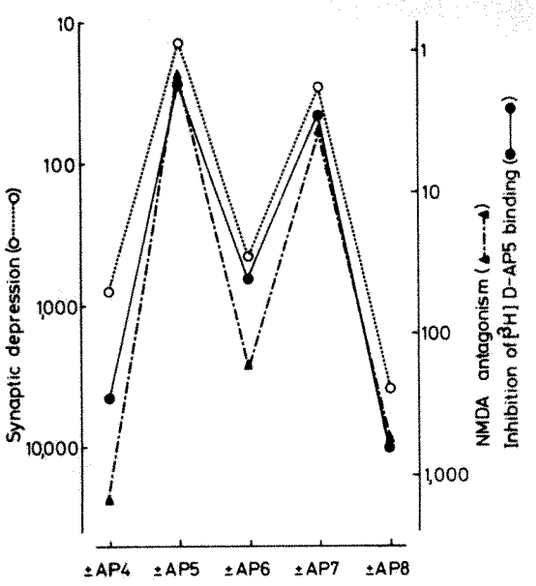

Fig. 3 Comparison of the effects of an homologous series of ω-phosphono-α-aminocarboxylates on electrically and NMDA-evoked responses recorded from ventral roots of frog spinal cord and on the binding of [^{3}H]-D-AP5 to rat cerebral cortical membranes. For details of electropharmacological measurements see ref. 2. [^{3}H]-D-AP5 binding was measured as described in Fig. 1, in the presence of concentrations of inhibitor between 10 nM and 1 mM. Left-hand ordinate scale and open circles indicate micromolar concentrations of phosphono-amino acid required to produce a 20% depression in amplitude of the pen recorded dorsal root-evoked ventral root potential. The right-hand ordinate scale and filled triangles indicate concentrations (μM) required to produce a dose ratio of two for antagonism of NMDA-evoked responses and filled circles the K_i value (μM) for inhibition of [^{3}H]-D-AP5 binding.

L-aspartate and L-Glutamate were more potent than their sulphinic and sulphonic acid analogues. In addition, all the amino acids of the glutamate chain length were more potent than aspartate and its analogues. L-Glutamate had the highest affinity of all agonists tested, being more than ten times as potent as L-aspartate, and having a K_i similar to that of D-AP5 itself. In contrast, quinolinate, a known selective NMDA type agonist[7], had only low affinity for the D-AP5 binding site.

The findings of this study may be compared with those of another investigation in which [^{3}H]-(±)-AP7 was used as the binding ligand[15]. Although there are several similarities in the results of the two studies, the conclusion[15] that [^{3}H]-AP7 binds predominantly to quisqualate-type receptors conflicts with our findings with [^{3}H]-D-AP5 and, indeed, is somewhat paradoxical. Like AP5, AP7 is considered highly selective for NMDA-type receptors in electrophysiological studies, and has little or no effect on quisqualate induced depolarizations[2]. It is possible that the nature of the AP7 binding site was transformed by the conditions used (notably the use of freeze-stored rather than fresh membranes). Alternatively, a misleading profile of binding inhibition may have been obtained by the use of the racemic form of [^{3}H]-AP7 rather than the pharmacologically active D(−) form of the substance[19].

The high affinity of L-glutamate for [^{3}H]-D-AP5 binding sites found in the present work contrasts with the apparent low sensitivity of L-glutamate-induced responses to such specific NMDA receptor antagonists[1]. However, the sensitivity of L-glutamate-induced responses to specific NMDA antagonists is probably masked by the actions of exogenous L-glutamate at other receptors[5], perhaps including extrasynaptic receptors not involved in transmission processes. A role of NMDA receptors in synaptic excitation is, however, well established[1].

The present results constitute the first evidence as to the relative affinities of endogenous (and likely endogenous) excitatory amino acids for NMDA receptors. While relative affinities do not necessarily identify a transmitter, clearly L-glutamate must be considered a strong candidate for the transmitter acting not only at kainate/quisqualate receptors, but at NMDA receptors as well.

We thank Dr R. B. Barlow for advice on computer fitting and Mr D. J. Oakes for technical assistance. This work was supported by the Wellcome Trust and the MRC.

The responses of vertebrate neurones to glutamate involve at least three receptor types[1]. One of these, the NMDA receptor (so called because of its specific activation by *N*-methyl-D-aspartate), induces responses presenting a peculiar voltage sensitivity[2–6]. Above resting potential, the current induced by a given dose of glutamate (or NMDA) increases when the cell is depolarized[4–6]. This is contrary to what is observed at classical excitatory synapses, and recalls the properties of 'regenerative' systems like the Na^+ conductance of the action potential. Indeed, recent studies of L-glutamate, L-aspartate and NMDA-induced currents have indicated that the current–voltage (I–V) relationship can show a region of 'negative conductance' and that the application of these agonists can lead to a regenerative depolarization[4–6]. Furthermore, the NMDA response is greatly potentiated by reducing the extracellular Mg^{2+} concentration ($[Mg^{2+}]_o$) below the physiological level (~1 mM)[7,8]. By analysing the responses of mouse central neurones to glutamate using the patch-clamp technique[9], we have now found a link between voltage sensitivity and Mg^{2+} sensitivity. In Mg^{2+}-free solutions, L-glutamate, L-aspartate and NMDA open cation channels, the properties of which are voltage independent. In the presence of Mg^{2+}, the single-channel currents measured at resting potential are chopped in bursts and the probability of opening of the

0028–0836/84/050462—04$01.00

© 1984 Macmillan

channels is reduced. Both effects increase steeply with hyperpolarization, thereby accounting for the negative slope of the *I–V* relationship of the glutamate response. Thus, the voltage dependence of the NMDA receptor-linked conductance appears to be a consequence of the voltage dependence of the Mg^{2+} block and its interpretation does not require the implication of an intramembrane voltage-dependent 'gate'.

The experiments were performed on mesencephalic or striatal neurones from 13- or 15-day-old mouse embryos which were kept in culture for 6–10 days as described by Beaujouan *et al.*[10]. In the two patch-clamp configurations used ('whole-cell recording' and 'outside-out patches')[9], the pipette solution usually contained (mM): CsCl, 140; NaCl, 4; HEPES-K, 10 (*p*H 7.2); $CaCl_2$, 0.5; EGTA 5 (*p*Ca = 7.3), and the extracellular solution contained: NaCl, 140; KCl, 2.8; $CaCl_2$, 1.0; HEPES-Na, 10 (*p*H 7.2). Neurones used for whole-cell recordings were typically less than 12 μm in diameter with two or three fine processes. We can therefore assume that most of the cell membrane was adequately clamped in the whole-cell recording mode. The agonists, L-glutamate (referred to below as glutamate), L-aspartate, NMDA, quisqualate and kainate, were applied by bath perfusion.

In the whole-cell recording mode, when the membrane potential was held at −60 mV in a Mg^{2+}-free solution, glutamate (2–10 μM) elicited, in most neurones, an inward current which remained stable over periods of up to 10 min.

The effects of membrane potential and Mg^{2+} on the glutamate-activated current are illustrated in Fig. 1*a*. In the absence of extracellular Mg^{2+}, the glutamate-induced current varied nearly linearly with membrane potential. The reversal potential was 0 mV. The addition of extracellular Mg^{2+} (500 μM) produced little change in the outward currents, but markedly reduced the inward currents. The blocking effect of Mg^{2+} increased as the cell was hyperpolarized.

The effect of Mg^{2+} on the glutamate-induced current noise (Fig. 1*b*) was parallel to that observed on the total current. The power spectra of the glutamate-induced noise were well fitted by single lorentzians having a similar cut-off frequency at −40 and +40 mV in Mg^{2+}-free solution, and at +40 mV in Mg^{2+} (500 μM) (Fig. 1*c*). Under the usual assumptions made in the spectral analysis of transmitter-induced currents[11], this indicates that the mean open time of the channels opened by glutamate in Mg^{2+}-free solutions is independent of membrane potential. This open time is nearly 5 ms at 27 °C (Fig. 1*c*) and 3 ms at 30 °C (Fig. 1*b*). It is not altered by Mg^{2+} (1 mM) in the positive potential range.

We repeated the experiments described above on outside-out patches. In Mg^{2+}-free solutions, glutamate (1–10 μM) activated a homogeneous population of channels. With CsCl-containing pipettes, the elementary current varied linearly between −80 mV and +40 mV, inverting around 0 mV. The value of the single-channel conductance was 49 ± 8 pS ($n = 14$). When CsCl in the pipette was replaced by KCl, the analysis at potentials above −40 mV became difficult due to the currents flowing through the voltage-dependent K^+ channels. Between −80 mV and −40 mV, however, the glutamate-induced single-channel currents were identical to those measured with CsCl inside the pipette. In one experiment, external Cl^- was replaced by isethionate and the elementary current through the glutamate-activated channels was unchanged. These results suggest that the channels opened by glutamate are cation channels discriminating only slightly between monovalent cations, and

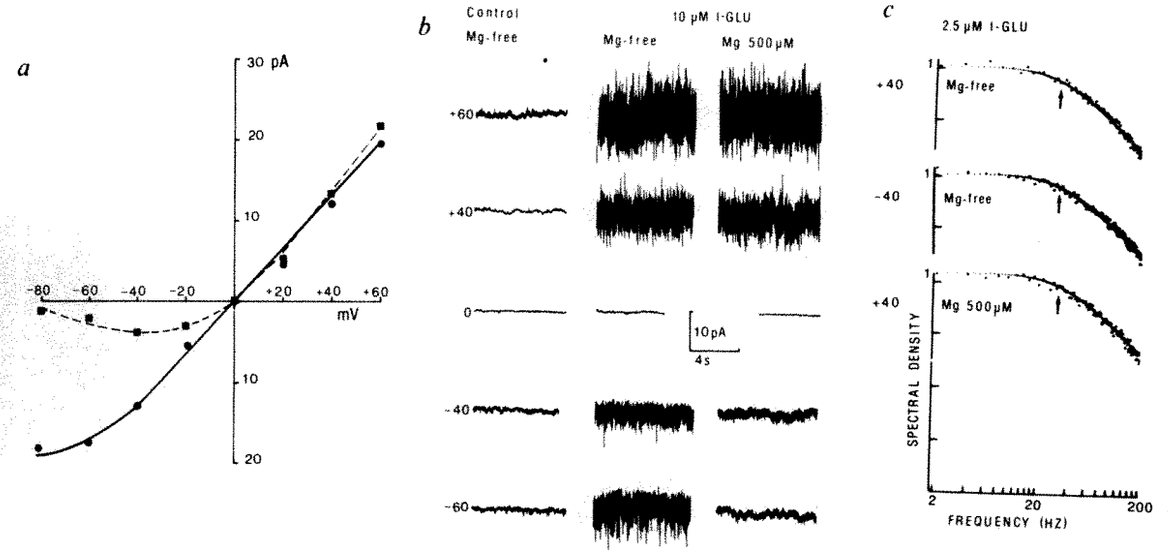

Fig. 1 Glutamate-induced currents in the whole-cell recording mode. ***a***, Voltage dependence of the glutamate-induced current. The glutamate-activated current was calculated at each potential as the difference between the current measured in control (Mg^{2+}-free or 500 μM Mg^{2+}) solutions and after addition of glutamate (10 μM). In a Mg^{2+}-free solution (●), the *I–V* relationship is approximately linear between +60 and −60 mV. The bend observed below −60 mV was not observed in all experiments, although in many cases the slope of the *I–V* relation was smaller in the negative potential range than in the positive range. In a solution containing Mg^{2+} (500 μM) (■), the currents are reduced at negative potentials, and the *I–V* relationship shows a 'negative resistance' region. In the positive potential range, no significant change is observed. ***b***, Glutamate-induced current noise. Same experiment as in *a*. The d.c. shift of the current is not illustrated. The control traces shown in the left-hand column were taken in Mg^{2+}-free solution in the absence of glutamate. The records of the central column were taken after the addition of glutamate (10 μM) (Mg^{2+}-free solution), and the records on the right were taken in a solution containing Mg^{2+} (500 μM) and glutamate (10 μM). The control records for 500 μM Mg^{2+} solutions (not shown) were identical to those shown for Mg^{2+}-free. ***c***, Power spectra of glutamate-induced current noise. In this experiment, the concentration of glutamate was 2.5 μM. Each spectrum was obtained by subtraction of control spectra from spectra recorded in the presence of glutamate. Spectral density: arbitrary units, log scale. The cut-off frequencies are: 34.5 Hz (upper record), 31.8 Hz (middle record) and 32.5 Hz (lower record). These frequencies correspond to respective time constants of 4.6, 5.0 and 4.9 ms. Temperature: 30 °C (*a*, *b*); 24 °C (*c*).

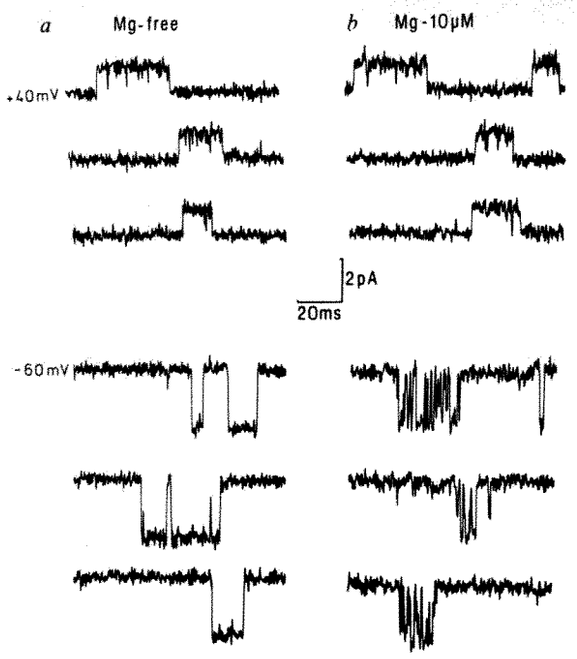

Fig. 2 Glutamate-induced single-channel currents in outside-out patches. In Mg^{2+}-free solution (*a*), the single-channel currents appear as simple events on both sides of the reversal potential (about −5 mV in this experiment). After addition of Mg^{2+} (10 μM) (*b*) the currents recorded at +40 mV are unchanged whereas the currents recorded at −60 mV appear as bursts. The size of the single-channel current is not altered by the addition of 10 μM Mg^{2+}. At higher Mg^{2+} concentrations (50–100 μM) an apparent reduction of the elementary current was observed (not shown), but this probably only reflects the inability of the recording system to display faithfully the transient openings of the channels. In this experiment, $MgCl_2$(2 mM) had been added to the internal solution. Note that the single-channel conductance is 51 pS at −60 mV, and only 33 pS at +40 mV. This discrepancy was observed in all experiments where Mg^{2+} (2 mM) was present in the internal solution but was not seen when Mg^{2+} was absent. Thus, when Mg^{2+} was absent both from the internal and external solutions, the *I*–*V* relationship of the glutamate-induced current was linear (between −60 and +60 mV) at the single-channel level as well as (Fig. 1) at the whole-cell level.

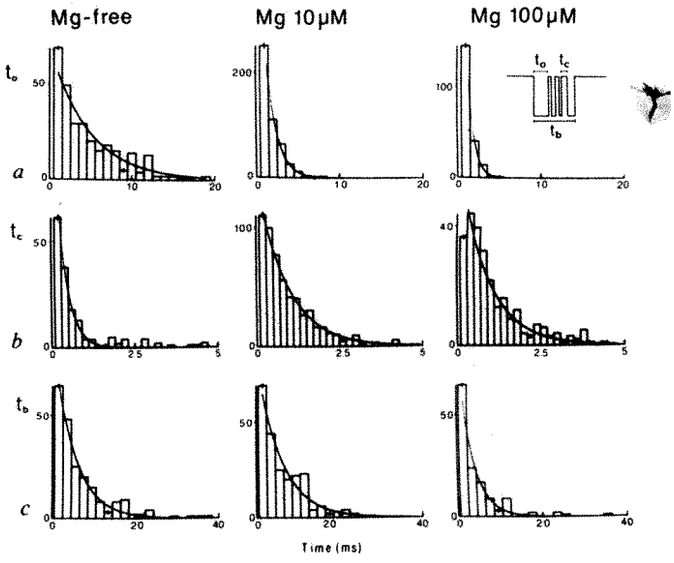

Fig. 3 Histograms of time intervals between open and closed states. Same experiment as in Fig. 2. Data recorded at −60 mV and analysed as described by Trautmann and Siegelbaum[23]. Bin length: 1 ms (*a*), 0.2 ms (*b*), 2 ms (*c*). Ordinate: number of observations. The insert (upper right) shows examples of open time (t_o), short closed time (t_c) and burst duration (t_b) used for analysis. *a*, Distribution of open times (t_o). The mean open time, $\bar{t}_o$, measured as the time constant of the exponential fitted on the histogram, was 4.7 ms in Mg^{2+}-free solution, 1.2 ms in 10 μm Mg^{2+}, and 0.7 ms in 100 μM Mg^{2+}. *b*, Distribution of short closed times (t_c). The values plotted are the durations of the short closures (gaps) inside the bursts illustrated in Fig. 2. The mean value, $\bar{t}_c$, was 0.3 ms in Mg^{2+}-free solution, 0.88 ms in 10 μM Mg^{2+}, and 0.84 ms in 100 μM Mg^{2+}. The last two values are comparable, as expected from a simple fast channel block model, in which they would imply a value close to $1{,}100\ s^{-1}(1/\bar{t}_c)$[14,18] for the rate constant of dissociation of Mg^{2+} from the channel. The $\bar{t}_c$ values in Mg^{2+}-free correspond to rare events, one of which is illustrated in Fig. 2*a*, middle record at −60 mV, Mg^{2+}-free. The gaps observed in such 'control' conditions were not analysed in detail, but their frequency and mean duration were similar at −60 mV and at +40 mV (not shown). *c*, Distribution of burst durations (t_b). The burst durations were measured by the same method as the open time, except that gaps of less than 5 ms (instead of gaps of 0.5 ms in the case of open times) were ignored. The time constant of the exponential, $\bar{t}_b$, was 5.7 ms in Mg^{2+}-free solution, 4.9 ms in 10 μM Mg^{2+}, 3.2 ms in 100 μM Mg^{2+}. The difference between $\bar{t}_o$ and $\bar{t}_b$ in Mg^{2+}-free solutions corresponds to the presence of the few gaps mentioned above.

resembling in this respect the glutamate-activated channels of the insect neuromuscular junction[12,13].

The open-time distribution of the single-channel currents could be reasonably well fitted by a single exponential with a voltage-independent time constant. Finally, the frequency of occurrence of the channel openings was (in a given patch) not noticeably affected by membrane potential. It thus appears that in Mg^{2+}-free solution, the three 'elementary' properties of the individual channels (elementary conductance, mean open time and frequency of opening) are, to a first approximation, voltage independent.

In the presence of extracellular Mg^{2+} (10 μM) the single-channel currents observed at positive potentials were identical to those recorded in the absence of Mg^{2+}, but at negative potentials major modifications were observed. The most striking change (Fig. 2) was that each channel opened in a burst, in a pattern similar to that first observed by Neher and Steinbach[14] in their study of the effects of local anaesthetics on acetylcholine-induced currents.

The appearance of such bursts suggested that extracellular Mg^{2+} may be acting by a 'fast channel block' mechanism[14–18]. We attempted to test some of the predictions of the simplest form of this scheme, in which Mg^{2+} ions block only the open state. If we call $\bar{t}_o$ the mean open time of a channel, $\bar{t}_b$ the mean duration of the group of openings constituting a burst, and $\bar{t}_c$ the mean value of the gap duration (blocked time) inside a burst[14,18] (see insert, Fig. 3), the fast channel block scheme predicts that as the Mg^{2+} concentration, $[Mg^{2+}]_o$, increases, $\bar{t}_o$ should decrease while $\bar{t}_c$ should remain constant. These two predictions were verified in the experiment illustrated in Fig. 3. However, the simple sequential scheme also predicts that, at low Mg^{2+} concentrations, the burst duration should increase when $[Mg^{2+}]_o$ increases, whereas the total charge carried during a burst should remain constant (see also ref. 19). This prediction was not verified. As illustrated in Fig. 3, the burst duration decreased when $[Mg^{2+}]_o$ was increased, and this effect was enhanced by hyperpolarization (not shown).

That a simple fast-channel block model cannot account for all the blocking effects of Mg^{2+} is further indicated by the fact (Fig. 4) that Mg^{2+} reduces the frequency of opening of the glutamate-induced channels. This effect and the reduction of burst duration (illustrated in Fig. 3) may well be the result of a common underlying mechanism, for example, slow channel block[20] or increased desensitization[21]. In general, it is premature to propose any specific scheme but it seems clear that the blocking effect of Mg^{2+} involves at least two voltage-dependent processes, one accounting for the fast flickering of the single-channel current, the other explaining the reduced frequency of

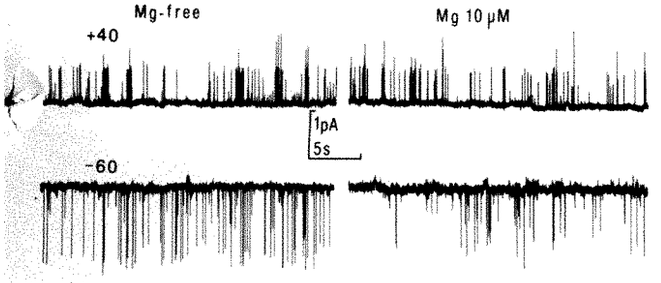

Fig. 4 Glutamate-induced currents in outside-out patches. Same experiment as in Fig. 2. The records, taken at slow speed on a chart recorder, illustrate the reduction in the frequency of channel openings produced by Mg^{2+} (10 μM) at −60 mV (lower records), whereas no change in frequency is observed at +40 mV (upper records). The small size of the elementary currents, and the apparent reduction of their size by Mg^{2+} (−60 mV) both result from the filtering introduced by the chart recorder and were not present when the currents were displayed on an oscilloscope (Fig. 2).

channel openings. A similar dual block has been recently proposed for the Na^+ block of some K^+ channels[22].

The hypothesis that the Mg^{2+}-sensitive glutamate-activated channels are of the NMDA type was supported by the finding that, both in the whole-cell recording mode and in outside-out patches, NMDA (2–10 μM) and L-aspartate (10 μM) elicited responses similar to those induced by L-glutamate, while kainate (up to 10 μM) and quisqualate (up to 5 μM) were ineffective.

Thus, our observations provide an explanation for the ionic mechanism of the glutamate response associated with NMDA receptors. Whereas early observations had suggested that glutamate may act through a K^+ conductance decrease[3], more recent work has indicated that L-glutamate, L-aspartate and NMDA all induce a voltage-dependent conductance increase[4–6]. Our data confirm this interpretation and further indicate that the channels opened by glutamate are permeant to both Na^+ and K^+. In addition, they suggest that the voltage dependence of the conductance does not result from a direct effect of the membrane potential on the receptor–channel complex but rather is the consequence of a voltage-dependent Mg^{2+} blockade.

Voltage-gated K^+ channels in human T lymphocytes: a role in mitogenesis?

Thomas E. DeCoursey*, K. George Chandy†, Sudhir Gupta† & Michael D. Cahalan*

* Department of Physiology and Biophysics and † Division of Basic and Clinical Immunology, Department of Medicine, University of California, Irvine, California 92717, USA

Membrane receptors and ion transport mechanisms probably have an important role in lymphocyte activation leading to T-lymphocyte proliferation in the immune response. Here we have applied a gigaohm-seal patch clamp technique[1] to reveal the identity and properties of ion channels in human T lymphocytes. A voltage-dependent potassium channel bearing a resemblance to the delayed rectifier of nerve and muscle cells was found to be the predominant ion channel in these cells. In the whole cell recording conformation, the channels open with sigmoid kinetics during depolarizing voltage steps, reaching a maximum K^+ conductance of 3–5 nS. The current subsequently becomes almost completely inactivated during a long-lasting depolarization. Currents through single K^+ channels recorded in whole cell and outside-out patch recording conformations reveal a unitary channel conductance of about 16 pS in normal Ringer solution. Thus, the peak current corresponds to approximately 200–300 conducting K^+ channels per cell. Phytohaemagglutinin (PHA), at concentrations that produce mitogenesis, alters K^+ channel gating within 1 min of addition to the bathing solution, causing channels to open more rapidly and at more negative membrane potentials. ^{3}H-thymidine incorporation by T lymphocytes following PHA stimulation is inhibited by the 'classical' K^+ channel blockers tetraethylammonium and 4-aminopyridine, and also by quinine, at doses found to block the K^+ channel in voltage-clamped T lymphocytes, suggesting that K^+ channels may play a part in mitogenesis.

Figure 1 shows outward potassium currents recorded from a human T lymphocyte in the whole cell conformation. Depolarizing voltage steps up to −40 mV given from a holding potential of −80 mV produce very small leakage currents, representing an input resistance of greater than 20 GΩ for this cell. At −30 mV, outward current is just noticeable, and larger depolarizing pulses produce larger outward currents as more channels open. The current is carried by K^+ ions from the cytoplasm in diffusional equilibrium with the pipette solution. If the extracellular K^+ concentration is raised to the concentration within the pipette (not shown), we observe inward K^+ current below a well defined reversal potential near 0 mV. During a depolarizing pulse, the voltage-gated K^+ channels open after an initial delay and then slowly become inactivated. The inactivation process most closely resembles the K^+ channel inactivation described in molluscan nerve cell bodies[2] displaying 'cumulative inactivation', as shown in the inset of Fig. 1. Here, two identical voltage pulses to 0 mV are given, separated by 50 ms. The slow decline of current during the first pulse is interrupted by repolarization, and during the second pulse current rises to a lower level than at the end of the first pulse. This phenomenon has been modelled in a kinetic scheme with two separate inactivated states for the channel[3].

The K^+ channel inactivation process has two consequences for our experiments. First, because recovery from inactivation is very slow, pulses delivered faster than every 20 s result in decreasing current magnitude during a pulse series. We have found that replacement of chloride by fluoride in the pipette solution helps to provide the stability required at low pulse frequencies, allowing recording over a period of hours with little rundown. Second, because inactivation is nearly complete at depolarized potentials, it is possible to record current through single channels in the whole cell conformation, as illustrated in

© 1984 Macmillan Journals Ltd

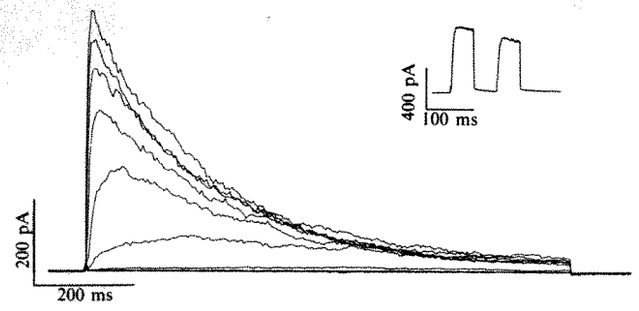

Fig. 1 Currents recorded from a T lymphocyte in the whole cell conformation. Peripheral blood was obtained from healthy volunteers (initials given in figure legends), and T lymphocytes were separated as described previously[29]. The membrane potential was held at −80 mV, and depolarizing pulses were given every 20 s in 10 mV steps up to +30 mV. Currents were recorded with a 10 GΩ feedback resistor, with active lowpass filtering at 2 kHz. Cell from S.C. Inset: a K^+ current record illustrating cumulative inactivation. Twin depolarizing pulses to 0 mV from a holding potential of −80 mV. Cell from S.G. T lymphocytes were suspended in medium RPMI-1640 supplemented with 10% human AB serum, 25 mM HEPES, 100 U ml^{-1} penicillin, 100 μg ml^{-1} streptomycin and 2 mM L-glutamine (Gibco), and maintained at 37 °C in humidified 5% CO_2 atmosphere. In three separate determinations the cell population studied contained more than 90% T lymphocytes, estimated by Leu-1 (Pan T, Becton-Dickinson) monoclonal antibody binding and fluorescence activated cell sorter analysis. All voltage clamp measurements were made at room temperature (20–22 °C). The pipette input resistance, usually 3–6 MΩ, was measured with the pipette in the bath, and was used to set the series resistance compensation. The cells were bathed in a mammalian Ringer solution containing (in mM) 160 NaCl, 4.5 KCl, 2 $CaCl_2$, 1 $MgCl_2$ and 5 HEPES, at *p*H 7.4. The pipette contained an 'internal' solution consisting of 140 KF, 1 $CaCl_2$, 2 $MgCl_2$, 11 K_2EGTA and 10 HEPES, *p*H 7.2 (free Ca^{2+} concentration less than 2×10^{-9} M, based on a solubility product of 3.4×10^{-11} M^3 for CaF_2[30]. High resistance seals (often 50–200 GΩ) sometimes formed spontaneously on touching the pipette to the cell surface, but more often after application of a small negative pressure (usually <20 cm H_2O). Whole cell recording was achieved by applying strong negative pressure to the pipette interior (more than 100 cm H_2O) in order to disrupt the membrane patch within the pipette.

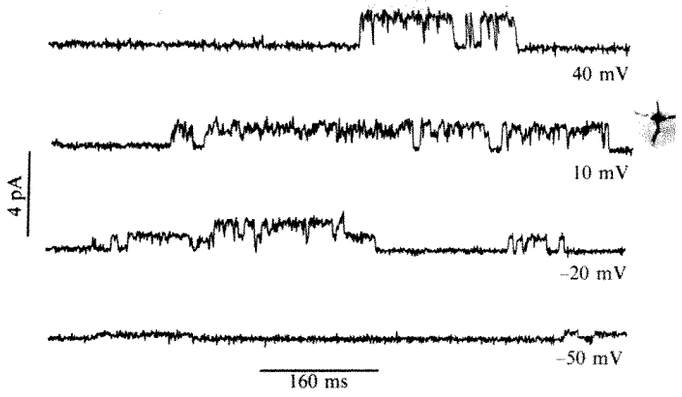

Fig. 2 Single K^+ channel currents recorded from a T lymphocyte in the whole cell conformation. Same bathing and pipette solutions as Fig. 1. Membrane potential held at potentials indicated. 800 Hz filter. Cell from S.G.

Table 1 Viability of T lymphocytes exposed to K^+ channel blockers

Expt	Treatment	% Viability (Trypan)	^{3}H-thymidine (c.p.m. ± s.d.)
I	Control	83	17,000 ± 5,000
	4AP + PHA	87	19,700 ± 9,100
II	Control	95	51,400 ± 2,700
	TEA + PHA	92	48,200 ± 4,800
III	Control	100	73,600 ± 3,400
	Quinine + PHA	94	53,400 ± 9,300

T lymphocytes (2×10^6 ml^{-1}) were incubated in sterile 12 × 75 mm tubes in medium described in Fig. 1 at 37 °C in humidified 5% CO_2 in the presence of 50 μg ml^{-1} PHA and 8.6 mM 4AP, 20 mM TEA or 100 μM quinine, for 48 h. Control T lymphocytes were suspended in medium alone for the same duration. Cells were then washed thrice in Hank's balanced salt solution supplemented with 25 mM HEPES, resuspended in media at 10^6 cells ml^{-1} and viability assessed by Trypan blue dye exclusion. The cells were then cultured in microtitre plates (10^5 cells per well) and incubated with 8 μg ml^{-1} PHA, and ^{3}H-thymidine uptake was measured 64 h later. Cells were from M.T. (I), N.W. (II) and K.C. (III). Viability in the presence of 4AP and TEA was assessed in three additional determinations by Trypan blue dye exclusion with similar results. All concentrations given are final concentrations.

Fig. 2. When the membrane potential is stepped and held at a depolarized level, K^+ current is first turned on and then becomes inactivated nearly to zero, with single channel events seen above the background noise. From records such as these, and from outside-out recordings in which the patch is excised from the cell (not shown), we estimate a single channel conductance of about 16 pS in normal Ringer. The single channel currents are 'flickery' and tend to become inactivated with rapid pulsing, whether recorded from intact cells on first making a seal, from whole cells as in Fig. 2, or in outside-out patches. Dividing the mean maximum whole cell conductance, 4 nS, by the single channel conductance, provides an estimate of at least 250 conducting K^+ channels per cell, although more channels may be present than those opening during a large depolarization.

In a small number of cells, whole cell recording revealed qualitatively different outward currents that slowly become activated at potentials above 0 mV and fail to become inactivated. This minority population of cells may represent contaminating non-T cells that are present in the T-lymphocyte-enriched population at a frequency of about 10%. In more than 90% of the cells studied, the voltage-gated K^+ channel described here was clearly dominant in the recordings. Our recording conditions, with very low free calcium concentration and fluoride in the pipette, may have prevented our seeing other channels that might be present in intact T lymphocytes, such as calcium channels reported to be present in a B-cell myeloma line[4] or calcium-activated channels. Calcium currents in snail neurones are abolished by internal perfusion with fluoride-containing solutions[5]. The K^+ channel described here differs from calcium-activated 'maxi-K^+' channels described previously in other tissues[6,7] in its calcium sensitivity, gating properties, single channel conductance and pharmacological sensitivity. The free Ca^{2+} in our pipette solution was only 2 nM (see Fig. 1 legend), whereas 1–10 μM internal Ca^{2+} is required to activate Ca^{2+}-dependent 'maxi-K^+' channels with the voltage dependence found in the present work[8–10]. We have not investigated the possible dependence of the K^+ channel on intracellular free Ca^{2+} concentration. Sigmoid activation kinetics and voltage-dependent inactivation are characteristic of delayed rectifier K^+ channels, but not Ca^{2+}-activated K^+ channels. The ubiquitous maxi-K Ca^{2+}-activated channels have a very large unitary conductance, 100–240 pS[6], although Ca^{2+}-activated K^+ channels of 20–50 pS, closer to the 16 pS found here, have been reported in *Helix* neurones[11,12] and in red blood cells[13], but have not yet been well characterized. Pharmacological experiments provide additional characterization of the voltage-gated K^+ channels. T-lymphocyte K^+ channels are blocked reversibly in a dose-dependent manner by tetraethylammonium (TEA), 4-aminopyridine (4AP) and quinine. Figure 3*a* illustrates dose–response curves for channel block by these three agents. The curves represent a one to one drug molecule–receptor relationship, fitted by eye to the measured fractional current remaining at various drug concentrations. Quinine is the most potent, with an inhibitory constant, K_i, of

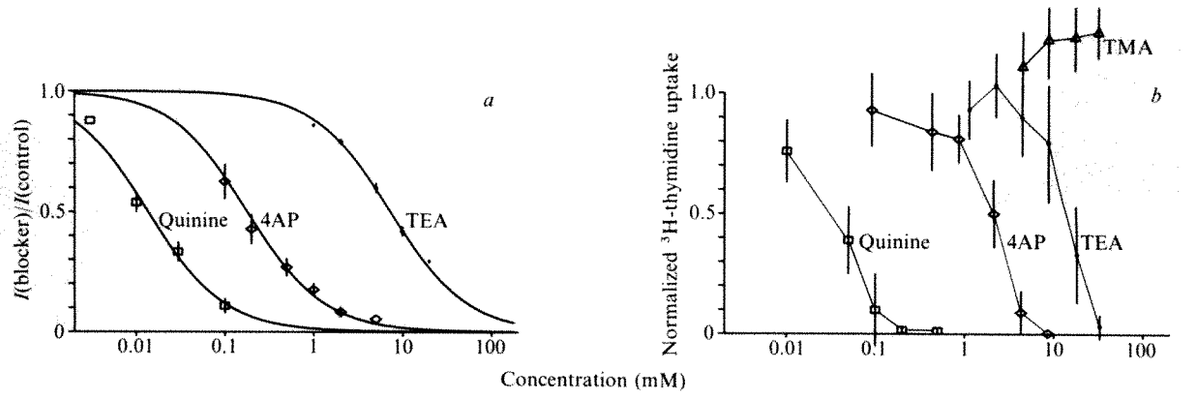

Fig. 3 Dose-response curve for blockade of the K^+ channel (*a*) and inhibition of mitogenesis (*b*) by quinine (□), 4AP (◇) and TEA (●) in T lymphocytes. Also shown in (*b*) are data for tetramethylammonium (TMA, △), which did not appreciably block K^+ currents. *a*, Data points show the mean K^+ current remaining in the presence of the indicated concentration of blocker added to Ringer solution. Cells from S.G., S.B., E.S. and M.T. PHA, at concentrations used for mitogenesis, seemed to have no effect on blocking by TEA or 4AP, and for these blockers data in the presence and absence of PHA have been pooled. s.e. bars are shown for means including data from three or four cells. In all experiments the membrane potential was held at −80 mV and stepped briefly to +20 mV every 30 s. After leak subtraction the peak current in the presence of blocker was normalized to the average of control currents recorded before addition and after washout of blocker. The bath temperature was monitored with a thermistor, and current records were temperature matched to within 0.2 °C. The preparation was allowed to equilibrate in each test solution until the peak current amplitude appeared to have reached steady-state. In 4AP-containing solutions both block and recovery progressed more slowly than in quinine or TEA-containing solutions, and about 5 min was allowed before recording. Recovery from the first application of 4AP to a cell was about 90% complete, so data from the first exposure to 4AP were not included. The curves express a bimolecular interaction between blocker and channel, with the fractional current remaining expressed as $1/(1+(B/K_i))$, where B is the drug concentration and K_i is the equilibrium dissociation constant. The K_i adjusted by eye to fit the data points was 0.014 mM for quinine, 0.19 mM for 4AP and 8 mM for TEA. *b*, Cells from S.C., N.W., G.C., S.G., K.L., S.B. and M.T. 10^5 T lymphocytes per well in medium (Fig. 1 legend) were plated in 96-well round-bottomed microtitre plates (Corning) and incubated in the presence of PHA at a final concentration of 8 μg ml^{-1}, with or without quinine, 4AP or TEA at 37 °C in humidified 5% CO_2 for 64 h. Cells were pulsed with ^{3}H-thymidine (1 μCi per well) for the final 16 h. Stock solutions of blockers in medium were titrated to *p*H 7.2 and added to the cells to the appropriate final concentration. All experiments were done in triplicate. The data points show the mean and s.d. from three or four experiments, of ^{3}H-thymidine incorporation normalized to that in PHA-treated cells in the absence of blocker. Background counts from cells with no PHA added were always less than 200 c.p.m.

about 14 μM, followed by 4AP at 190 μM and TEA at 8 mM. Quinine is believed to block Ca^{2+}-activated K^+ channels, but this block is not specific[14]. In neuroblastoma cells, for example, quinine blocks both Ca^{2+}-activated and voltage-gated K^+ channels[15]. TEA also blocks both types of K^+ channels, whereas block by aminopyridines appears to distinguish between voltage-gated and Ca^{2+}-activated K^+ channels[7]. Thus, the K^+ channel described here seems to be distinct from any Ca^{2+}-activated channel described to date, but closely resembles voltage-gated delayed rectifier K^+ channels.

Phytohaemagglutinin is a potent mitogen for T lymphocytes, stimulating cell division by mechanisms that have been intensively studied[16–19]. Involvement of ionic channels at an early stage of PHA activation is suggested by reports of membrane depolarization[20], hyperpolarization[20,21], increased ion fluxes across the membrane[22,23] and increased intracellular free calcium[21,24]. We therefore studied the effects of the three K^+ channel blockers described above and found them to inhibit PHA-induced mitogenesis in a dose-dependent manner (Fig. 3*b*), with the same potency sequence as for channel block (Fig. 3*a*). These data suggest that mitogenesis is suppressed when some fraction (perhaps 50%) of the K^+ channels do not function. The relative potency of 4AP for channel block compared with inhibition of mitogenesis seems to be greater than that of TEA or quinine. This result may be due to scatter in the data, or it might reflect relief of 4AP block by depolarization, as reported in other tissues[25,26], since the normal lymphocyte resting potential is substantially more positive than the −80 mV holding potential used here[20,21,27,28]. Complete replacement of the external sodium by 160 mM tetramethylammonium (TMA), an analogue of TEA, produced very little reduction of K^+ currents (data not shown). Up to 33 mM TMA added to the medium did not inhibit mitogenesis, showing that the inhibition by TEA was not due to the higher osmolarity of the medium. Table 1 shows that T lymphocytes incubated for 48 h in the presence of PHA and 4AP, TEA or 100 μM quinine were viable, as assessed by Trypan blue dye exclusion and by the ability to respond normally to added PHA after washing. Viability was reduced by 200 μM quinine. 4AP did not nonspecifically prevent ^{3}H-thymidine uptake and incorporation because 4AP added at the time of thymidine addition, 48 h after PHA activation, did not alter thymidine incorporation.

PHA may bind to cell-surface glycoproteins, producing effects by altering membrane transport properties. Since the voltage-gated K^+ channel described above is the predominant ion channel in our patch clamp experiments, we studied the influence of PHA on the kinetics of K^+ channel gating. Figure 4 illustrates the major immediate effects of PHA on the K^+ channel. In this cell before PHA addition (Fig. 4*a*), K^+ current was just noticeable during depolarizing pulses to −20 mV. At more positive potentials more channels open. Shortly after adding 3 μg ml^{-1} PHA (Fig. 4*b*), current was noticeable at −40 mV, about 20 mV more negative than the control. As shown in Fig. 4*c* the conductance–voltage relationship appears steeper and shifted towards hyperpolarized potentials after PHA treatment, with little or no change in the maximum conductance. Taking the potential required to activate half-maximal conductance as a measure and pooling the data for eight cells at PHA concentrations of 3–100 μg ml^{-1}, PHA produced a hyperpolarizing shift of −15 ± 3.5 mV (mean ± s.e.m.), with larger PHA concentrations tending to produce larger shifts. At a given potential the channels opened more rapidly following addition of PHA, causing a decrease in the time to peak current, also seen in Fig. 4. The effect of PHA was not readily reversed by washing with normal Ringer. The primary action of PHA may be to increase the voltage-dependent rate constants that lead to K^+ channel opening. If PHA acts by altering external surface charges 'sensed' by channel activation gates, our results indicate that the local surface potential would be more negative after PHA treatment. As a result of the alteration of K^+ channel gating by PHA more K^+ channels would be open on the average, possibly contributing to the hyperpolarization and increased K^+ fluxes previously

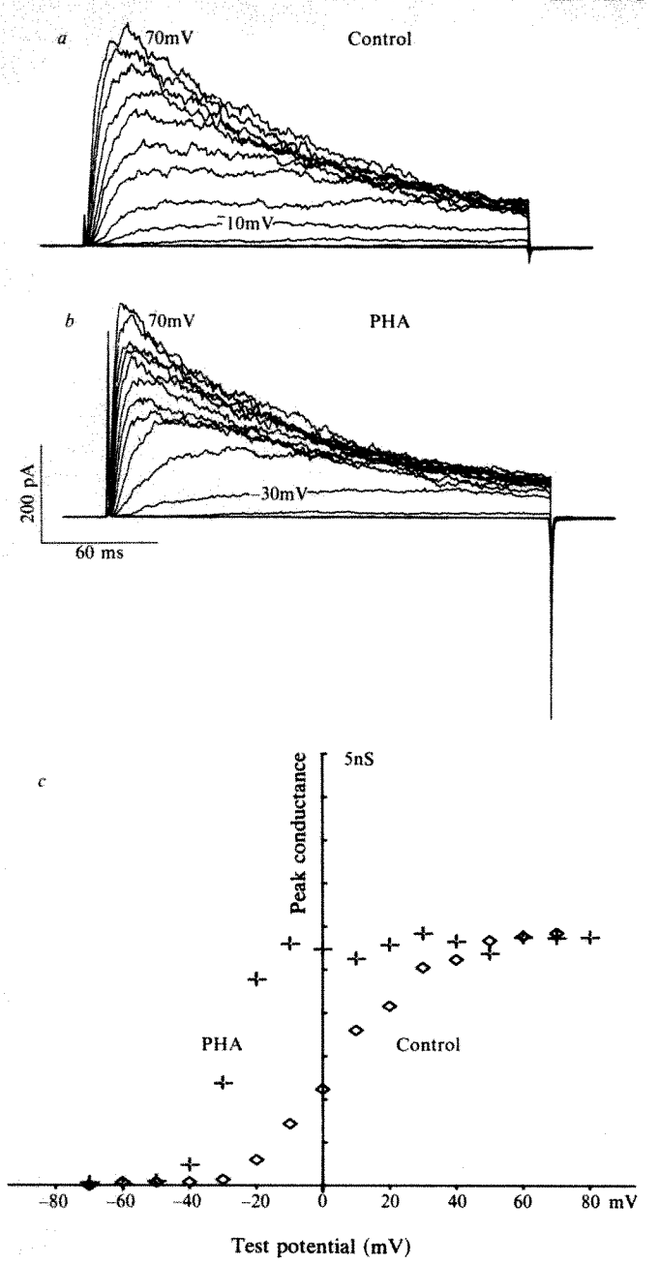

Fig. 4 *a* And *b* show whole cell currents recorded from a T lymphocyte from S.G. Same bathing and pipette solutions as previous figures, except 3 $\mu g\ ml^{-1}$ PHA (PHA-P, Difco) was added before recording currents in *b*. PHA solutions were mixed fresh daily from aliquots of frozen 10 $mg\ ml^{-1}$ stock solution. Same cell as Fig. 2. Depolarizing steps up to +70 mV in 10 mV increments were given every 20 s from the holding potential of −80 mV. *c*, The corresponding conductance–voltage relationships calculated by dividing the peak K^+ current at each depolarizing voltage step by the potential minus the measured reversal potential, −82 mV.

reported[21–24]. The rapid effect of PHA on K^+ channel gating, taken together with the inhibition of ^{3}H-thymidine incorporation by K^+ channel blockers, suggests that functioning K^+ channels altered by PHA may bring about a sequence of cellular and molecular events leading to DNA synthesis.

We thank Drs D. Corey, G. Yellen, R. Aldrich and V. Dionne for advice on patch clamp techniques, C. Rhodes and K. Lee for valuable technical assistance, and Dr J. Fernandez for advice on pipette solutions. This work was supported by grant NS14609 and by a Research Career Development Award to M.D.C. from the NIH, and a fellowship to K.G.C. from the American Diabetes Association, Southern California Affiliate.

K channels in T lymphocytes: a patch clamp study using monoclonal antibody adhesion

D. R. Matteson & C. Deutsch

Department of Physiology, University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania 19104, USA

Ionic fluxes are thought to be involved in mediating the proliferation of peripheral blood lymphocytes (PBLs) in response to mitogenic substances[1,2]. Among the earliest events occurring after the addition of mitogen to cultured lympocytes are changes in rates of cation transport[3–9]. We were interested, therefore, in the possible role of ion channels in mediating the lymphocyte proliferative response. The development of patch clamp techniques by Neher and colleagues[10–12] has made it possible to study membrane conductances in a variety of small cell types[12]. We have developed a method which uses monoclonal antibodies to make cells adhere to solid surfaces for two major reasons: (1) it is much easier to patch clamp stationary cells, and (2) the method can be used to selectively adhere a particular cell type from a heterogeneous population. We have used these techniques here to identify whole-cell potassium currents, in lymphocytes recognized by OKT11 monoclonal antibody, which are increased 1.9-fold by mitogenic stimulation.

Subclasses of human T lymphocytes, of ~7 μm diameter, were selectively adhered to solid surfaces (plastic Petri dishes and glass coverslips) using monoclonal antibodies of known specificity[13,14]. Human T-lymphocyte populations have been defined by the presence of antigenic determinants on the cell surface. Using flow cytometry we found that 75% of the cells in the monocyte-depleted PBL suspension were T lymphocytes recognized by monoclonal antibody OKT3 (Table 1). Of these T cells, 66% were predominantly helpers recognized by OKT4 and 30% were predominantly suppressor recognized by antibody OKT8.

To demonstrate selective adhesion, we used both indirect and direct immunofluorescence microscopy, the former being more sensitive than the latter. In all experiments, suspensions of PBLs

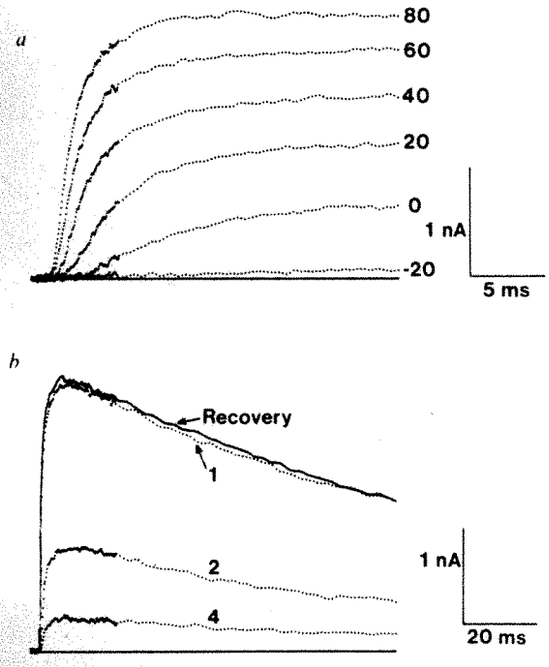

Fig. 1 Voltage-dependent outward currents in T lymphocytes. *a*, When lymphocytes were depolarized they generated an outward current. These currents were elicited by 25-ms step depolarizations to the indicated voltages from a holding potential of −70 mV. The currents in *b* were generated by 100-ms depolarizations to +100 mV. Dotted traces labelled 1, 2 and 4 resulted from first, second and fourth pulses, respectively, of a train delivered at 1.5 Hz, and the solid trace was recorded 74 s after the train. For this experiment, cells were attached with OKT11 and had been stimulated with succinyl concanavalin A for 20 h.

Methods: Patch electrodes, of 2–5 MΩ resistance, were made with borosilicate glass and filled with the following solution (mM): 140 KCl, 2 $MgCl_2$, 10 EGTA and 10 HEPES (*p*H 7.3). Just before recording, the solution bathing the antibody-adhered cells was changed to a protein-free solution of the following composition (in mM): 130 NaCl, 10 $CaCl_2$, 2 $MgCl_2$, 5 KCl and 10 HEPES (*p*H 7.3). After obtaining a gigaseal against the cell, further suction was applied to rupture the patch of membrane under the electrode tip. In these conditions, the electrode monitors current through the entire cell surface. The electrode was connected to a current-to-voltage (I–V) converter and the analog current signal was acquired with an LSI 11/23 computer at 50 kHz and stored for later analysis. Linear components of capactive and ionic current were subtracted out with a P/2 procedure[26]. Cells were voltage-clamped by controlling the positive input of the I–V converter.

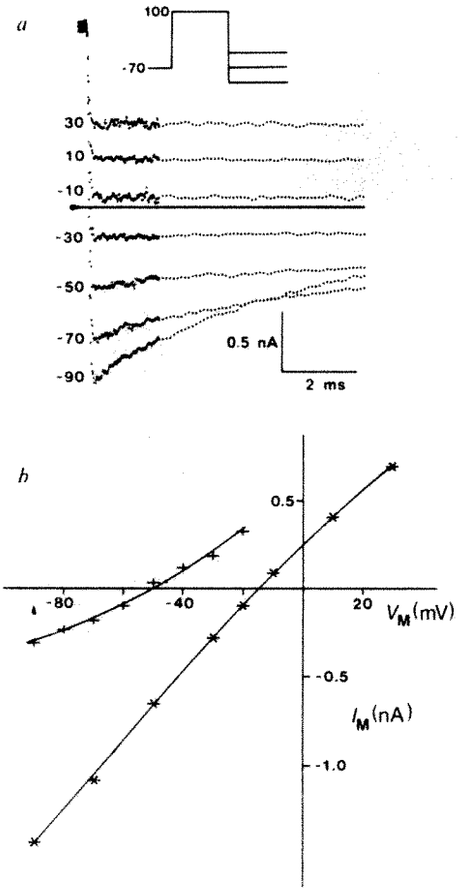

Fig. 2 K dependence of the reversal potential. The pulse protocol used to obtain the instantaneous current–voltage relationship is shown in the inset of *a*. The initial depolarization to +100 mV activated the outward current. The membrane was then stepped to various potentials and the resulting instantaneous change in current measured. For each trace shown in *a*, the first few points were taken before the pulse to provide a current baseline. Sampling was then stopped and restarted 200 μs before the second voltage step was applied. The voltage of the second step is indicated alongside each current trace. Pipettes were filled with the same solution as for Fig. 1 and the external solution had the following composition (mM): 85 NaCl, 60 KCl, 5 $CaCl_2$, 2 $MgCl_2$ and 10 HEPES. The magnitudes of the instantaneous currents shown in *a* (which were measured ~150 μs after the step because of the limited frequency response) are plotted in *b* (*); it can be seen that the current reverses direction at ~−15 mV. When the external solution contained only 15 mM K^+ (+) the reversal potential shifted to ~−50 mV. Cells were attached with OKT11 and had been stimulated with succinyl concanavalin A for 20 h.

were first depleted of monocytes by adhering these sticky cells to T150 tissue culture flasks (final monocyte content ~1%). For indirect immunofluorescence measurements, lymphocytes were incubated with either OKT3, OKT4 or OKT8 (Ortho Pharmaceutical Corp.), washed, made to adhere to goat anti-mouse IgG (Tago)-coated surfaces, then incubated with fluorescein-labelled Tago. In each case, almost all cells adhering to the surfaces were fluorescent. The following results were obtained in control experiments: (1) in the absence of antibodies, lymphocytes did not adhere to Tago-coated surfaces; (2) lymphocytes were not fluorescently labelled by incubation in suspension with fluorescein–Tago alone; and (3) Tago is necessary for adhesion of cells that have been labelled with monoclonal antibody. These results demonstrate that monoclonal antibody is necessary in order to observe fluorescence and adhesion, and therefore the specificity of the antibody imparts specificity to the cell attachment. Direct immunofluorescence measurements, in which adherent lymphocytes were incubated with OKT3, OKT4 or OKT8 (fluorescein-labelled) and then aliquoted onto Tago-coated surfaces, showed enhancement of the specific cell population on the surface, compared with its distribution in suspension (Table 1), again indicating selective adhesion. This adhesion method is accomplished by a simple protocol, is highly reproducible and could therefore be useful for a wide range of electrophysiological studies of specific cell types. In general, wherever cell types are distinguishable by their surface antigens, this method could be used to isolate particular cell types from heterogeneous populations.

We used this method to attach human lymphocytes for our patch clamp experiments. Cells were adhered with monoclonal antibody OKT3, 4 or 11. OKT11 is used for identification of human peripheral T lymphocytes; it binds to >95% of the cells that are E rosette-positive. The advantage of using OKT11 rather than OKT3 is that is is not mitogenic, and its use ensures that unstimulated cells are not activated by exposure to mitogenic antibody. We studied primarily OKT11-adhered cells, and in future studies we shall investigate those T-cell subsets predominantly recognized by OKT3, OKT4, OKT8 or other antibodies.

Table 1 Specificity of cell adhesion with monoclonal antibodies

Monoclonal antibody	% Positive in suspension	% Positive* bound to dish (direct immunofluorescence)	% Positive† bound to dish (indirect immunofluorescence)
OKT3	75.5	84	100
	74.9	85	
OKT4	49.9	64	100
OKT8	28.9	58	
OKT11			100

Human T lymphocytes were prepared from heparinized human venous blood which was collected from healthy donors, separated by gradient centrifugation using a modified Ficoll–Hypaque technique[25], suspended in minimal essential medium (MEM) or Hank's (Ca–Mg-containing medium) with 15% mixed human AB serum and incubated at 50×10^6 cells per flask (20 ml) in T-150 tissue culture flasks for 1.5 h. The supernatant was gently decanted, centrifuged at 1,500 r.p.m. for 10 min, resuspended in MEM and cultured in a 5% CO_2 incubator at 37 °C as described previously[25]. Goat anti-mouse IgG (Tago Inc., Burlingame, California; 1.5 ml of a 1:10 dilution in Tris buffer, *p*H 9.5) was added to a Falcon Petri dish (bacterial grade, 13×100 mm) at 0 °C and incubated for 40 min. After this time, the dishes were rinsed with cold Tris buffer then with cold phosphate-buffered saline (PBS, *p*H 7.2) and cells were poured onto the plate and placed in the cold (4 °C) for ⩾2 h. Coverslips (Corning) were treated in exactly the same way as the Falcon Petri dishes. Cells (1×10^6 ml^{-1}) suspended in 1 ml PBS/10% fetal calf serum (FCS) were incubated with fluorescein-labelled OKT3, 4 or 8 (0.5, 0.5 and 0.25 μg per sample, respectively) for 30 min, centrifuged and resuspended in 0.5 ml PBS. 0.25 ml was added to each coverslip and allowed to stand for 30 min at 0 °C. The coverslips were then washed in three successive rinse wells containing PBS and counted using a Zeiss fluorescence microscope (×40). In addition, 0.25-ml samples from the cell suspension were assayed using an Ortho-Spectrum III flow cytometer. Indirect immunofluorescence assays were carried out as described above, except that unlabelled OKT3, OKT4 and OKT11 (1 μg per 10^6 cells) were used. After incubation of the cell suspension on the coverslip for 30 min at 0 °C, the supernatant was removed and 100–200 μl of fluorescein–Tago (1:20 dilution) were added. The coverslips were then washed and the cells counted. All suspensions contained <1% monocytes. Those cells incubated with no antibody showed only weak autofluorescence.

* Fraction of labelled cells in 100–200 cells observed.

† No non-fluorescent cells were attached.

Macroscopic currents were recorded from human T lymphocytes using the whole-cell recording configuration of the patch clamp technique[12]. Gigaohm seals were routinely obtained on these cells with 2–5 MΩ borosilicate electrodes. When lymphocytes are depolarized, outward currents are generated (Fig. 1). Both the magnitude of the current and its activation kinetics increase as the membrane potential is made more positive. As a result of prolonged depolarization, the outward current inactivates (see Fig. 1*b*). Inactivation is manifested both as a decline in current during depolarization, and as a decrease in current magnitude during a train of voltage clamp steps.

Several lines of evidence indicate that K channels carry the outward current illustrated in Fig. 1. For example, we have shown that the reversal potential for the current is close to the K equilibrium potential. Reversal potentials were determined from instantaneous current–voltage relationships (see Fig. 2). With 60 mM K^+ outside and 140 mM K^+ inside, the current reversed at ~−15 mV whereas the K equilibrium potential predicted from the Nernst equation is −21 mV. When the external solution contained 15 mM K^+, the reversal potential shifted to −50 mV; the predicted shift is to −56 mV. Thus, the channel appears to be K-selective, but we have not conclusively identified the type(s) of K channels present. Agents that block K channels in other preparations block this conductance also. We have found that quinine (100 μM) reversibly blocks outward currents in human lymphocytes, which is consistent with previous reports that both the volume-induced and A23187-induced K and ^{86}Rb effluxes in these cells are blocked by quinine[15]. Cs^+ blocks K channels in several preparations[16,17], and we also find that the K currents in human T cells are abolished when K^+ in the patch electrode is replaced with Cs^+.

We were interested in comparing the K currents in mitogen-stimulated cells with those in unstimulated cells, because there are several precedents for mitogen-induced increases in plasma

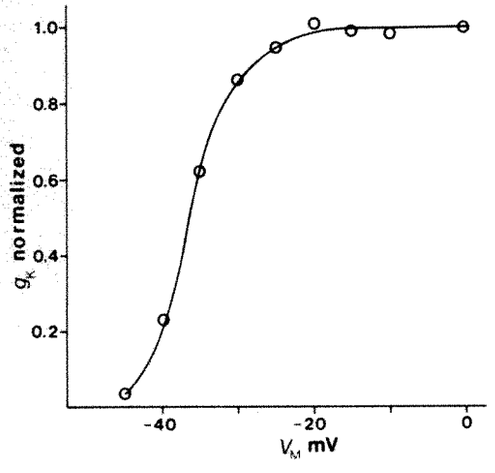

Fig. 3 Relationship of conductance to voltage. As the instantaneous *I–V* curve with 60 mM external K^+ is approximately linear, its slope was used as a measure of the K conductance activated during the initial depolarization (see also the pulse protocol in Fig. 2*a*). The activating voltage was varied in the range of membrane potentials indicated (V_M). The data points represent the average values obtained for three different cells 10–15 min after breaking into the cell. The midpoints of the individual conductance–voltage curves were at −35, −36 and −38 mV, indicating that they were in approximately the same position. The external solution contained (in mM): 85 NaCl, 60 KCl, 5 $CaCl_2$, 2 $MgCl_2$ and 10 HEPES (*p*H 7.3) and the internal solution contained (in mM): 100 KCl, 40 KF, 2 $MgCl_2$ and 10 HEPES (*p*H 7.3). Fluoride was included in the pipette solution because it increased the recording time in each cell. The K currents and the conductance–voltage relationship were not significantly different in the presence or absence of fluoride. The cells had been stimulated with succinyl concanavalin A for 24 h. Series resistance compensation was used as described previously[27].

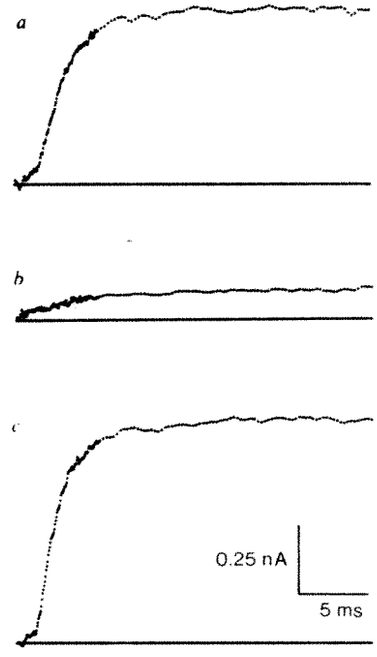

Fig. 4 External Ni^{2+} reduces K^+ currents in lymphocytes. The currents shown were generated by pulses to +50 mV and represent typical examples under the following conditions. *a*, Control current recorded in a solution of the following composition (in mM): 138 NaCl, 5 $CaCl_2$, 2 $MgCl_2$, 5 KCl and 10 HEPES (*p*H 7.3); *b*, after addition of 1 mM Ni^{2+} to the external medium; *c*, after returning to the control solution. Ni^{2+} clearly reduces the magnitude of the K current and the effect is reversible. The pipette solution was the same as for Fig. 3. Cells were stimulated with succinyl concanavalin A for 24 h.

membrane ion permeabilities[18–20]. Lymphocytes which had been stimulated with 50 μg ml^{-1} succinyl concanavalin A in culture for 20 h showed a 1.9-fold increase in K current. The current magnitude at +100 mV averaged 0.67 ± 0.31 nA (mean ±s.d.) in 15 unstimulated cells and 1.27 ± 0.66 nA in 21 stimulated cells, a difference that is significant ($P < 0.01$). It is not yet clear exactly what the relationship is between stimulated growth and increased K conductance. Additional studies are under way to determine whether the increase in conductance is due to an increase in number of channels or an increase in single-channel conductance.

To further characterize the K channels in mitogen-stimulated cells, we studied the relationship between membrane voltage and K conductance (g_K). Figure 3 shows that the threshold for g_K activation in human lymphocytes is ~ −45 mV, the midpoint of the curve is −36 mV and the conductance saturates at −20 mV. The maximum g_K averaged 11.8 ± 2.8 nS (mean ± s.d.) in 9 cells.

There is indirect evidence that the K conductance in human lymphocytes may, in part, be due to the presence of calcium-activated K channels. For example, in the presence of extracellular calcium, the Ca^{2+} ionophore A23187 causes a severalfold increase in ^{86}Rb efflux and uptake[15]. In addition, Tsien *et al.*[21] reported that in stimulated mouse thymocytes a rise in the concentration of intracellular free Ca was accompanied by cell hyperpolarization.

Therefore, we tried to obtain further evidence for the existence of Ca-activated K channels in human lymphocytes. One approach involved the use of Ni^{2+}, which is known to block Ca channels in other preparations[22]. Addition of 1 mM Ni^{2+} to the external medium reversibly reduced the K current, as illustrated in Fig. 4. This could reflect decreased Ca^{2+} entry which would result in a decreased activation of Ca-activated K channels. Alternatively, Ni^{2+} could be directly blocking the K channels, although we are not aware of any reports of this effect. Using Cs^+-filled electrodes to block the K conductance, we have been unable to observe any macroscopic Ca currents in these cells. Calcium channels may well be present in PBLs, but in numbers too small to detect as macroscopic current. By contrast, it is interesting that Fukushima and Hagiwara[23] found Ca channels in cultured myeloma cells; perhaps transformation is accompanied by an increased number of Ca channels[24].

In summary we have patch-clamped human T lymphocytes and identified potassium channels in both resting and mitogen-stimulated cells. Selective adhesion with monoclonal antibodies should allow us to characterize the membrane conductances of individual subsets of lymphocytes in a variety of conditions in which cellular and humoral immune responses occur.

This work was supported by NIH grant AM 27595, and by a research grant from the American Heart Association. C.D. is a recipient of a Research Career Development Award (AM 00838). We thank Dr J. Hoxie and Mr D. Mathews for their assistance with the immunofluorescence microscopy.

Retinoblastoma—origin from a primitive neuroectodermal cell?

The histogenesis of retinoblastoma, the most common intraocular neoplasm of childhood[1], remains controversial. Previous studies have attributed the origin of the tumour to neuronal, glial or primitive stem cells of retina[2–7]. In the study described here we have used immunofluorescence to search for the presence of a neuronal marker, neurone-specific enolase (NSE)[8,9] and a glial marker, glial fibrillary acidic protein (GFAP)[10,11], in the cells of the human retinoblastoma line Y-79 (ref. 4), before and after successful differentiation into neuronal and glial-like cells. We found that all undifferentiated cells contain both NSE and GFAP, whereas the differentiating neuronal and glial-like cells gradually lose one marker and selectively express the marker that correlates with their morphology. Our results support the notion that retinoblastoma originates from a primitive bipotential (or multipotential) neuroectodermal cell.

Monolayers of Y-79 cells were obtained in dishes precoated with poly-D-lysine and fibronectin and kept in both serum-supplemented and serum-free defined media[12]. N^6,O^{12}-dibutyryl adenosine 3′,5′-cyclic monophosphate (dbcAMP) was added to some dishes with serum-supplemented media[12]. Cells growing in serum-supplemented medium retained their conventional morphology of small round cells[12] (Fig. 1*a*), whereas cultures growing in serum-free defined medium showed extensive neuronal differentiation, consisting of a gradual increase in cells with neuritic-type processes (up to 30%) and rosette formation (Fig. 1*b*). In contrast, dbcAMP caused a small but significant increase in flat, glial-like cells (up to 10%) (Fig. 1*c*).

Indirect immunofluorescence was done in order to investigate the presence of NSE and GFAP in these cells. Normal rabbit serum (1 : 50) was always used as a negative control. A human neuroblastoma line, SMS-SAN (ref. 13) and a human glioma line, U-251MG (ref. 14), were used as positive and negative controls for each marker; human normal fibroblasts maintained in culture for >1 yr were used as a negative control for both markers. The specificities of the antisera were further tested by primary tissue staining of 5-μm sections from paraffin blocks of formalin-fixed tissue, by using the immunoperoxidase (PAP) method of Sternberger *et al.*[15]. The tissues examined included both positive and negative controls: normal human brain and spinal cord (tested with both antisera); an olfactory neuroblastoma, a pineoblastoma, a medulloblastoma, a mixed ependymoma–oligodendroglioma, a spinal and a cerebral astrocytoma, and a mixed grade 4 astrocytoma–meningeal sarcoma (tested with anti-GFAP); and five neuroblastomas, five lymphomas, one medulloblastoma, five Ewing's sarcomas and four soft tissue sarcomas (tested with anti-NSE). The diagnoses for all the above cases had been documented by light microscopy and when necessary, by electron microscopy and by additional means such as study of surface markers for lymphomas.

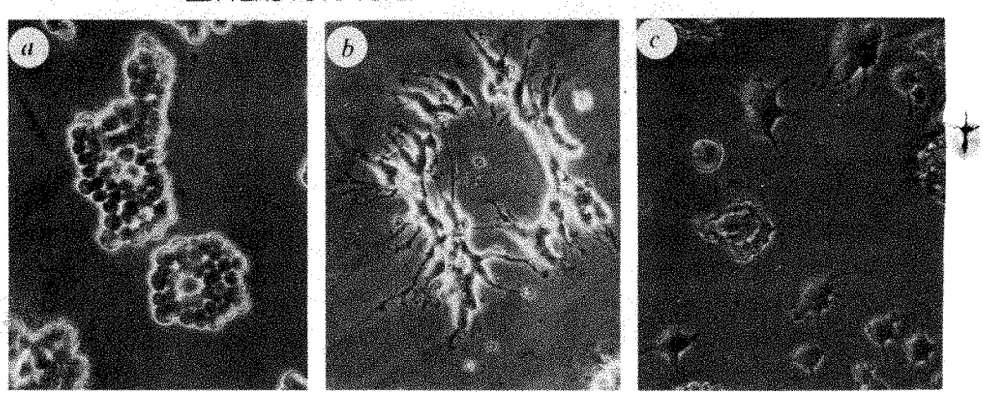

Fig. 1 Monolayers of the Y-79 cell line. *a*, Undifferentiated cells at 6 days in culture. Cells were seeded in 35-mm plastic dishes which had been pretreated with poly-D-lysine (0.2 mg ml^{-1}) at 23 °C for 6 min, washed once with minimum essential medium (MEM) containing 2 mM glutamine and 100 U ml^{-1} penicillin, and coated with fibronectin (5 μg ml^{-1}) at 37 °C for 30 min. The culture medium consisted of the medium described above, supplemented with 10% fetal bovine serum (×190). *b*, Cells demonstrating neuronal differentiation, at 22 days in serum-free, defined medium. Cells were seeded as for *a*, incubated for 2 h in serum-containing medium, and washed once with MEM. Finally, serum-free medium was added (supplemented with 5 μg ml^{-1} insulin, 10 μg ml^{-1} transferrin, 6.3 ng ml^{-1} progesterone, 8.8 ng ml^{-1} putrescine and 4 ng ml^{-1} sodium selinite) (×125). *c*, Flat cells with short cytoplasmic projections, resembling astrocytes (22 days in culture). In the centre there is a clump of small, closely packed undifferentiated cells. These cells were cultured in serum-containing medium; dibutyryl cyclic AMP (4 mM) was added at 3-day intervals beginning on day 8 of culture (five doses in total) (×155).

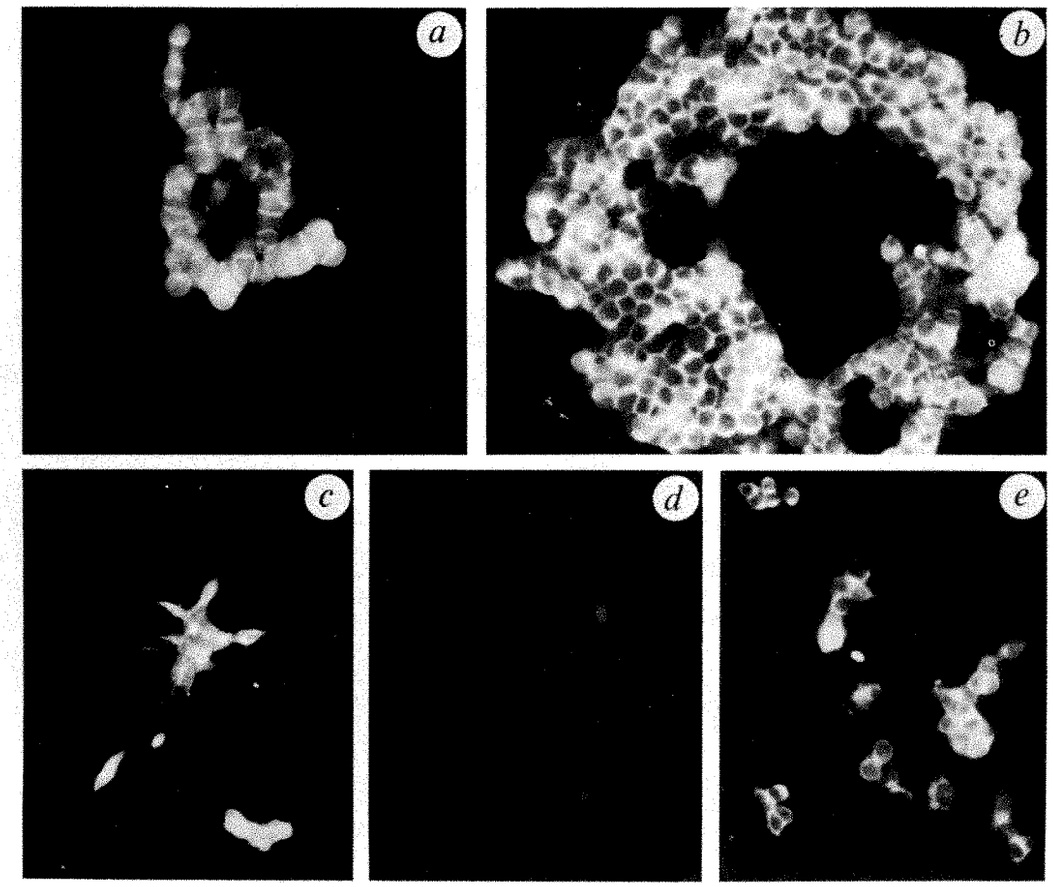

Fig. 2 Indirect immunofluorescence staining of Y-79 cells. Cells were fixed and incubated with antiserum as described in Table 1. *a*, Undifferentiated round cells positive for NSE (×257). *b*, Undifferentiated round cells positive for GFAP (×185). *c*, Cells with neuronal differentiation positive for NSE (×135). *d*, Flat glial-like cells negative for NSE. The flat cells are isolated; they are growing without forming clumps, chains or rosettes, in contrast to the undifferentiated or neuronal cells (×150). *e*, Flat cells positive for GFAP (×135).

The results of staining for the control and retinoblastoma cell lines before and after differentiation are given in Table 1. The pattern of staining for the control cell lines confirms the specificity of the antisera used in this study. Positive NSE staining was only observed in neuroblastoma cells. Anti-GFAP antiserum stained only glioma cells as reported previously[14–16], thereby obviating the possibility of cross-reactivity between GFAP and tubulin. Normal fibroblasts remained repeatedly negative for either marker, providing indirect evidence that our antisera did not cross-react with vimentin. A highly specific staining pattern was observed with immunoperoxidase also: that is, the neurones of the sections from brain and spinal cord as well as the cross-sectioned neuritic axons in the white matter of the spinal cord and adjacent spinal nerves were positive for NSE and negative for GFAP. In contrast, astrocytes in both tissues stained intensely positive for GFAP and remained negative for NSE. Among the other tissues examined, the olfactory neuroblastoma, pineoblastoma and the oligodendrocytic and sarcomatous components of the glial tumours, were negative for GFAP, whereas the astrocytomas and ependymoma were positive for GFAP, as reported previously[11]. The neuroblastomas were positive for NSE, whereas the lymphomas, Ewing's sarcoma and all soft tissue sarcomas were negative for NSE, as expected[17,18]. The medulloblastoma was generally negative for both NSE and GFAP, except for occasional GFAP-positive cells, previously interpreted as glial differentiation of the tumour[19].

All cells of the Y-79 human retinoblastoma line showed the simultaneous presence of NSE and GFAP before their differentiation into neuronal and glial-like (flat) cells respectively (Fig. 2*a*, *b*). The anti-GFAP antiserum gave a higher intensity of staining overall than the anti-NSE antiserum. One-third of the cells with neuronal differentiation in the defined medium were

Table 1 NSE and GFAP reactivity of retinoblastoma and control cells *in vitro*

Type of cell line	NSE reactivity	GFAP reactivity
(1) Retinoblastoma (Y-79)		
Undifferentiated	+	+
Differentiated*		
a Neuronal	+	+/−
b Glial-like	−	+
(2) Neuroblastoma (SMS-SAN)	+	−
(3) Glioma (U-251-MG)	−	+
(4) Normal fibroblasts	−	−

All cultures were fixed in absolute ethanol at −200 °C for 4 min and subsequently washed in phosphate-buffered saline (PBS). Primary antisera raised in rabbit against rat NSE (1:50; Polysciences, Warrington, Pennsylvania) and human GFAP (1:100; Accurate, Westbury, New York) were applied to all cultures at 4 °C for 24 h. The cultures were subsequently washed in PBS, incubated for 1 h with swine anti-rabbit IgG linked to fluorescein isothiocyanate (FITC) (1:20), washed again in PBS and observed under a Zeiss Standard microscope equipped with an epifluorescence illuminator and FITC narrow-band filter.

* The staining results for NSE and GFAP refer only to the differentiated cells. The cells which remained undifferentiated always retained both markers. One-third of the cells with neuronal differentiation became GFAP-negative, whereas all glial cells became NSE-negative.

GFAP-negative. All neuronal cells showed a higher intensity of NSE reactivity (Fig. 2*c*) than the undifferentiated cells. On the other hand, flat cells in dbcAMP-treated cultures were always negative for NSE (Fig. 2*d*), whereas most of them were positive for GFAP (Fig. 2*e*).

The simultaneous presence of NSE and GFAP in the retinoblastoma cells suggests that these cells originated from a primitive neuroectodermal cell capable of differentiation into neuronal and glial elements. Thus far, NSE and GFAP have not been detected simultaneously in another tumour either *in vivo* or *in vitro*. Morphological transformation of the retinoblastoma cells into neuronal and glial-like cells with specific staining patterns for NSE (neuronal) and GFAP (glial) reinforces the concept of the primitive bipotential nature of retinoblastoma. The fact that two-thirds of the cells in serum-free medium, despite their morphological differentiation into neuronal cells, retained their GFAP positivity suggests that they were in an earlier stage of biochemical differentiation. Both neuronal and glial cells have been described previously in retinoblastomas *in vivo* and *in vitro*[3,6,7,20]. However, the neoplastic nature of the glial cells in retinoblastoma has so far been a moot point. The present system obviates this problem, as it appears that the neoplastic cells differentiate into both neuronal and glial-like cell types and express biochemical patterns which correlate with the morphological phenotype of the differentiating cells.

The potential of the embryonal retinal cell to differentiate into neurones and glial cells has been shown by Ohnishi[21] and Fujisawa *et al.*[22] in dissociated neuroretinal cells of chick embryos. We have shown here that the same phenomenon can occur in the neoplastic counterpart of retinal cells—the retinoblastoma cell. An analogous situation exists in differentiating neuroblastoma (neural and Schwann cells)[23,24] and medulloblastoma (neuronal and glial cells)[19]. In both cases, the primitive tumour cells are presumed to have differentiated into neuronal and supporting cells. One can speculate that retinoblastoma is the result of exuberant proliferation of residual primitive retinal cells, or that dedifferentiation of mature retinal cells towards a more primitive neuroectodermal cell is necessary as a prelude to the neoplastic behaviour. It is interesting that the coexistence of neurofilaments (previously seen only in neurones) and vimentin (previously seen in some forms of glia) has been reported recently in the axonless horizontal cell of the outer plexiform layer in mouse retina, leading to the conclusion that this cell might represent an intermediate stage of differentiation between neuronal and glial cells[25].

This is the first time that *in vitro* differentiation of retinoblastoma has been achieved and studied morphologically and cytochemically. We believe that the present study will contribute to our knowledge of the origin and biological behaviour of retinoblastoma. It may also provide a system to assess the effects of various agents on tumour maturation *in vitro*, which may ultimately effect a potential cure *in vivo*.

We wish to thank Dr Alan Rabson for helpful comments during preparation of the manuscript.

A novel 6:10 chromosomal translocation in the murine plasmacytoma NS-1

Roger M. Perlmutter, Joan L. Klotz*, Dimitrina Pravtcheva†, Frank Ruddle† & Leroy Hood

Specific chromosomal abnormalities are regularly associated with many murine and human malignancies[1,2]. In particular, the majority of murine plasmacytomas and human Burkitt's lymphomas contain a characteristic translocation which results in the juxtaposition of a cellular oncogene, c-*myc*, with the immunoglobulin heavy-chain gene locus[3–7], and this rearranged c-*myc* directs the synthesis of qualitatively and quantitatively abnormal transcripts which may have an aetiological role in the development of the transformed state in lymphoid malignancies[8,9]. Similarly, rearrangement and abnormal expression of c-*myb* (ref. 10) and c-*mos* (ref. 11) has been reported in other murine lymphoid tumours. Here we describe a novel 6:10 chromosomal translocation in the murine plasmacytoma cell line NS-1 which juxtaposes the immunoglobulin C_κ gene with a single-copy sequence of unknown function. The NS-1 plasmacytoma is a frequently used fusion partner in hybridoma production[12] and is known to contain a rearranged c-*myc* gene[4,13] and a genetic element which transforms normal mouse fibroblasts in DNA-mediated transfection assays[14]. We conclude that individual B-cell tumours may contain multiple chromosomal translocations perhaps relevant to oncogenesis.

Phage clones containing C_κ sequences were isolated from a genomic library of hybridoma DNA prepared using the L47.1

© 1984 Macmillan Journals Ltd

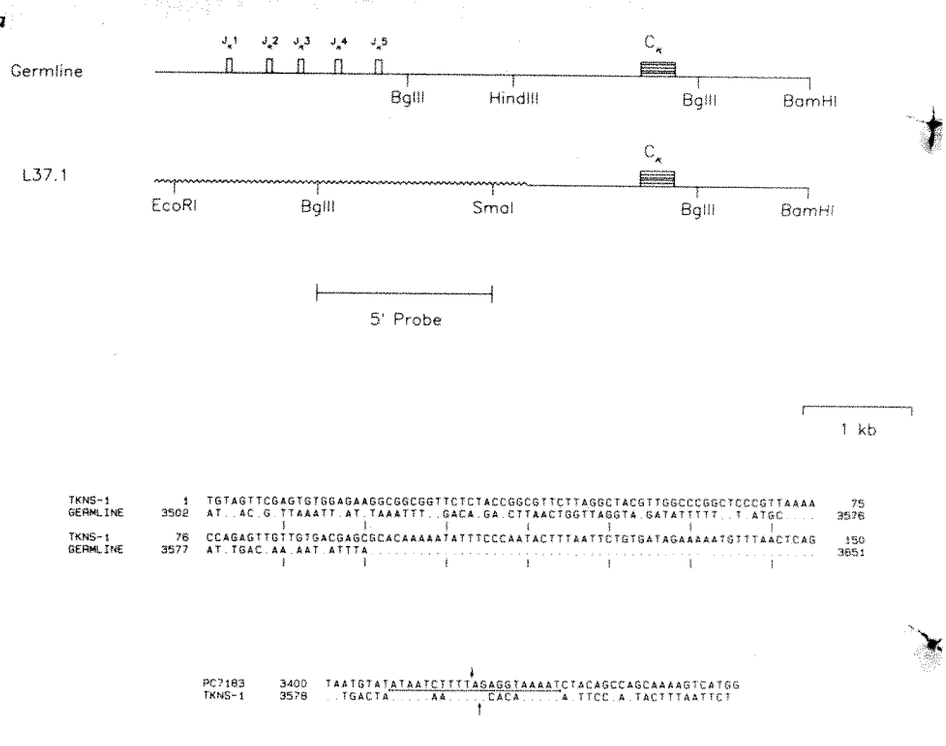

Fig. 1 *a*, An aberrantly rearranged C_κ gene. Genomic DNA was isolated from the HGAC9 hybridoma (secreting antibody to group A streptococcal carbohydrate[32]) and partially digested with *Mbo*I to allow construction of a library in L47.1 phage (see ref. 15). On screening with a murine C_κ gene probe, several clones were obtained which contained a novel sequence juxtaposed to C_κ. Restriction enzyme maps for the germ-line C_κ locus and for one of the rearranged clones, L37.1, are shown. The rearranged sequence begins just 3′ to the germ-line *Hin*dIII site and is denoted by a wavy line. A *Sma*I/*Bgl*II digest was used to generate a probe for this sequence (5′ probe) which was subcloned into M13mp8 (BRL). *b*, DNA sequence at the site of the T_κNS-1 translocation site. The T_κNS-1 sequence was determined by the chain termination method of Sanger[33]. The germ-line sequence is from ref. 34. Numbering of the T_κNS-1 sequence is arbitrary; numbering of the germ-line sequence reflects ref. 34. Homologous bases are indicated with dots. The remainder of the T_κNS-1 sequence extending towards the C_κ gene agrees precisely with the published sequence for this region[34]. *c*, Two potential target sites for translocation in the C_κ intervening sequence. The points of translocation for PC7183[20] and for T_κNS-1 (this paper) within the germ-line C_κ intervening sequence[34] are compared (arrows). The solid line denotes a 21-bp sequence, straddling the recombination points, which is closely homologous for both translocation sites.

phage vector[15]. Several overlapping clones were obtained which contained the C_κ gene and an aberrant sequence joined 1 kilobase (kb) 5′ to the C_κ gene (Fig. 1*a*). A 1.6-kb fragment derived entirely from this novel 5′ sequence was prepared by digestion with *Sma*I and *Bgl*II endonucleases (Fig. 1*a*) and used to probe Southern blots of BALB/c sperm DNA and DNA from various cell lines. Figure 2 shows that this probe identifies a single-copy sequence in germ-line (sperm) DNA but that both the hybridoma cell line from which the library was prepared (HGAC9) and the parent line NS-1 contain a rearranged copy of this sequence which results from the juxtaposition of C_κ (Fig. 1*a*). Thus, the C_κ rearrangement which we cloned from a specific hybridoma was present in the common parent cell line.

To identify the chromosomal location of the single-copy sequence aberrantly joined to the C_κ gene in NS-1 cells, we used mouse–hamster somatic cell fusion lines which retain limited numbers of different murine chromosomes[16]. Southern blot analysis of DNA from a number of such lines using our 1.6-kb probe unambiguously localized this sequence to chromosome 10 (Fig. 3). Thus, a 6:10 translocation in the NS-1 plasmacytoma fuses the C_κ gene on chromosome 6 to a single copy element from chromosome 10. We call this element T_κNS-1.

Because of the recent demonstration of translocations involving c-*myc* and immunoglobulin genes in murine plasmacytomas, we sought to identify a retroviral oncogene within the T_κNS-1 sequence. Using cloned v-*onc* probes, we were unable to identify any sequence homologous to *src*, *myb*, *myc*, *abl*, *ras*^{H}, *ras*^{K}, *fes*, *yes*, *sis*, *mos*, *rel*, *bas*, *erb*, *fms* or *fos* in the ~8 kb of DNA 5′ to C_κ in this cloned translocation (refs 17, 18 and data not shown). Similarly, the T_κNS-1 probe did not detect any rearranged sequences in NIH3T3 fibroblast transformants generated using murine plasmacytoma DNA which therefore contain the previously described plasmacytoma transforming element known to be present in NS-1 cells (ref. 14 and R.M.P. and M. A. Lane, unpublished observation). We conclude that T_κNS-1 probably does not include a previously described oncogene sequence.

As 90% of BALB/c plasmacytomas appear to contain a 12:15 chromosomal translocation[3-5,9,19], we examined 10 different B-cell tumours using Southern blotting and the T_κNS-1 probe to assess the frequency of this specific rearrangement. No other examples of this translocation event were identified. In this sense the T_κNS-1 6:10 translocation resembles a complex 6:12:15 translocation recently characterized by Van Ness *et al.*[20] which was also localized to the C_κ intervening sequence and which is also exceedingly infrequent in murine plasmacytomas (M. Weigert, personal communication). Thus, if these translocations predispose to malignant transformation, they are clearly not essential for the development of B-cell neoplasia. In this regard, we may speculate that the C_k intervening sequence could be particularly susceptible to chromosomal rearrangements.

DNA sequence analysis of T_κNS-1 at the translocation breakpoint reveals little homology between the C_κ intervening sequence and the novel element derived from chromosome 10 (Fig. 1*b*). Involvement of immunoglobulin switch sequences in the aberrant rearrangement of c-*myc* has suggested that normal B-cell differentiation mechanism may be involved in the genesis of the 12:15 translocation in plasmacytomas[4-6]. This explanation cannot apply to either the T_κNS-1 translocation or the 6:12:15 translocation described in PC7183[20] because both occur in a region of the C_κ intervening sequence which does not ordinarily undergo DNA rearrangements.

Interestingly, careful comparison of the translocation points within the C_κ intervening sequence found in NS-1 and PC7183, which are separated by 180 bases, reveals a region of homology (15/21 base pairs, bp) straddling these sites (Fig. 1*c*). A search of the entire C_κ locus sequence, nearly 6 kb, identified these as the only two regions containing a sequence homologous to the T_κNS-1 target site. This raises the possibility that some translocations occur via a site-specific mechanism.

Three properties distinguish the region immediately 5′ to the C_κ gene. First, heteroduplex analysis has established an area of conserved sequence between human and mouse DNA about 700 bp 5′ to the C_κ gene[21]. In addition, this region contains a DNase-I hypersensitive site, felt to reflect gene activation for increased expression[22], in approximately the same position as the man–mouse sequence homology[23-25]. Finally, the C_κ inter-

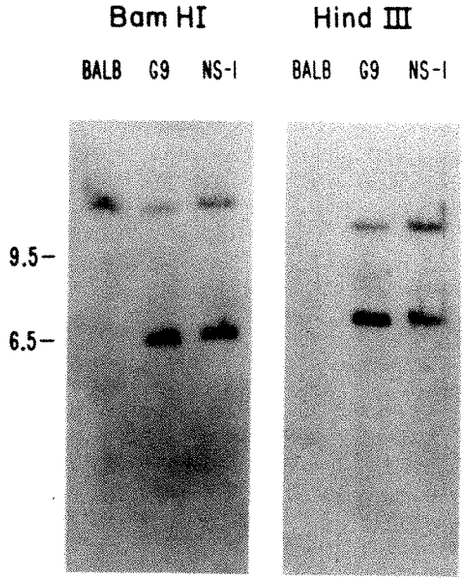

Fig. 2 The L37.1 rearranged C_κ gene is derived from the NS-1 hybridoma parent. Southern blots of 10 μg genomic DNA from BALB/c sperm, HGAC9 hybridoma cells or NS-1 plasmacytoma cells digested with *Bam*HI (left panel) or *Hin*dIII (right panel) were performed using the 1.6-kb *Sma*I/*Bgl*II 5′ probe shown in Fig. 1 labelled to 10^8 d.p.m. with ^{32}P-nucleotide triphosphates by primer extension[35]. After electrophoresis in 0.7% agarose, fragments were blotted onto nitrocellulose and hybridization was performed in 50% formamide at 42 °C as described previously[36]. The blots were washed in 0.015 M sodium citrate, 0.15 M sodium chloride, 0.1% SDS at 68 °C for 2 h before autoradiography overnight at −70 °C using Kodak XAR-5 film (Eastman Kodak) and an intensifying screen. The positions of standard size markers derived from *Hin*dIII fragments of phage λ DNA are noted in kb at the left.

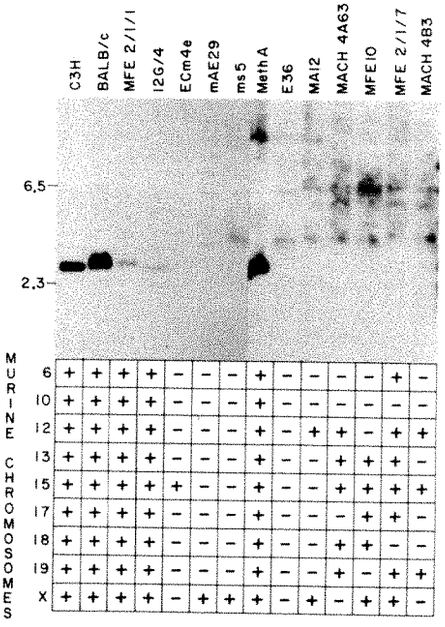

Fig. 3 Chromosomal location of T_κNS-1. Patterns obtained when genomic DNA from the indicated mouse strains (C3H, BALB/c), from a BALB/c sarcoma (MethA), a Chinese hamster cell line (E36) and mouse–hamster somatic cell fusion lines generated using MethA as a parent (ms5, mAE29, MA12) or BALB/c embryo fibroblasts as parent cells (MFE2/1/7, MFE2/1/1, MFE10), or A/HeJ macrophages as parent cells (MACH4AG3, MACH4B3) is analysed by Southern blotting as described in Fig. 2 legend. The origin of cell line Ecm4e has been described previously[37]. The DNA was digested with *Eco*RI which produces a 2.8-kb band that hybridizes with the *Sma*I/*Bgl*II probe used in Fig. 2. The specific murine chromosomes retained in each hybrid line are indicated with a plus sign. To simplify the figure, the complete karyotype of each cell line is not indicated. Chromosome 12 has been rearranged in the MFE10 cell lines. Hazy bands larger than 3.0 kb reflect cross-hybridization with homologous hamster-derived sequences. The positions of standard size markers are again indicated in kb at the left. Additional hybrid cell lines examined included MFE8, which contains all murine chromosomes except 6 and Y and which was positive for T_κNS-1 as was 12G/3, which lacks murine chromosomes 1, 3, 4, 7, 9, 11 and Y. Cell line 12G/2 lacking chromosomes 1, 2, 3, 4, 7, 9, 10, 11, 12, 14, 18, 19 and Y also lacked the T_κNS-1 band. Chromosomes not shown in the figure but present in the cell lines were as follows: MFE2/1/1: 1, 2, 3, 4, 7, 8, 9; 12G4: 5, 14, 16; ECm4e: 14; mAE29: 14; MACH4AG3: 2, 4, 7, 8, 16; MFE10: 1, 2, 7, 8, 9, 11, 14, 16; MFE2/1/7: 1, 2, 3, 7, 8, 9; MACH4B3: 2, 7, 16.

vening sequence has been shown to contain an enhancer element located 3′ to the *Hin*dIII site which dramatically increases transcription of C_κ-containing plasmids introduced into murine lymphoid cells[26–28]. Although translocation may occur randomly throughout the genome, as has been proposed for retroviral transduction[17], we find it provocative that two independent translocation events in murine plasmacytomas occur at highly homologous sites 180 bp apart in a sequence apparently organized to support active gene expression.

The NS-1 plasmacytoma line was developed from a mineral oil-induced tumour, MOPC-21, after adaptation to culture conditions and selection for sensitivity to hypoxanthine–aminopterin–thymidine medium[12] and we cannot be certain at which point during the genesis of NS-1 the T_κNS-1 6:10 translocation occurred. The fact that recent isolates of MOPC-21 do not contain this translocation[29] may reflect deletion of a κ allele during propagation of this tumour. In addition to the T_κNS-1 translocation, the NS-1 cell line contains a characteristic 12:15 translocation event of murine plasmacytomas, an activated oncogene common to most murine plasmacytomas[14], and a rearrangement in c-*mos* apparently analogous to that described in XRPC24 (ref. 11 and N. Takahashi, personal communication). Although the simultaneous coexistence of these four sequence abnormalities may in part reflect chromosomal instability within cultured cell lines, it is significant that three of these four abnormalities involve genes having known transforming potential. One possible explanation might be that these oncogenes act in concert, together providing growth advantages not present when only one is expressed[30] or perhaps developed sequentially, reflecting multiple stages in oncogenesis[14,31]. Thus, chromosomal translocations in neoplastic cells may provide a window for the selective identification of important genetic elements involved in differentiation and growth control.

We thank Bennett Berson for technical assistance, C. Katz for typing the manuscript, Drs M. Nahm and J. M. Davie for the gift of HGAC9 hybridoma cells, Dr M. Kronenberg for normal tissue ahd hybridoma mRNA, Dr M. Cline for cloned oncogene probes, and Drs R. Barth, M. Kronenberg and E. Kraig for critical reading of the manuscript. This work was supported by grants from the NIH; R.M.P. is the recipient of a USPHS New Investigator Award.

Activation of N-*ras* gene in bone marrow cells from a patient with acute myeloblastic leukaemia

Christof Gambke*, Erich Signer† & Christoph Moroni*

* Friedrich Miescher-Institut, PO Box 2543, CH-4002 Basel, Switzerland
† Children's Hospital, University of Basel, Basel, Switzerland

Human tumour cell lines of various histological origin contain genes that can transform NIH 3T3 cells in culture[1,2]. Most frequently the gene is an activated K-*ras* gene, more rarely an activated H-*ras* gene, and sometimes the recently discovered N-*ras*[3–11]. Other transforming genes, distinct from *ras*, have been found in B- and T-cell leukaemias[9,12]. Since most of the transforming genes have been identified in cell lines, it is still unclear at what stage the genes become activated. We have therefore initiated a study to determine if the presence of a transforming gene correlates with the clinical course of a malignant disease. Here we demonstrate the presence of a transforming N-*ras* gene in bone marrow cells from a patient with acute myeloblastic leukaemia at the outbreak of the acute disease phase. Fibroblast DNA from the same patient was not transforming. In contrast to HL-60 cells[13,14], no alteration of the *myc* gene was detected.

A 9-year-old girl with anaemia and leukocytosis was admitted to the hospital where an acute myeloblastic leukaemia (AML) M2 (ref. 15) was diagnosed. Clinical and laboratory findings are summarized in Table 1. An aliquot of this patient's diagnostic bone marrow aspirate, obtained before chemotherapy administration, was examined for the possible presence of a transforming gene. AML DNA was found to contain focus-forming activity in three consecutive experiments (Table 1*a*). Four foci from three different plates were picked using cloning cylinders and grown into cell lines of clearly transformed morphology. The DNA from these lines was prepared and tested in a secondary transfection experiment to determine whether the putative transforming gene could be transferred. Table 1*b* shows that this DNA could induce foci on NIH 3T3 cells.

DNA derived from primary and secondary foci was subjected to Southern blot analysis using BLUR-8[16] as a probe for the detection of human repetitive *Alu* sequences in the transfection foci. Figure 1 shows that a representative primary focus (lane *b*) contains a large number of human repetitive DNA sequences. Three secondary foci (lanes *c–e*) share an *Alu*-containing fragment of ~8.8 kilobases (kb). A fourth secondary focus lacks this fragment, but contains two fragments of ~20 and 6 kb. We tentatively conclude that the transforming activity is associated with the 8.8-kb fragment, and perhaps with the 20- or 6-kb fragment. To characterize the transforming gene further we tested its sensitivity to seven restriction enzymes by digesting primary focus DNA before the transfection experiment. Focus formation was reduced 10-fold or more by digestion with *Eco*RI, *Hin*dIII, *Bam*HI or *Pvu*II, while *Xho*I, *Sal*I and *Cla*I did not reduce the focus-forming activity of the DNA preparation (data not shown). This restriction enzyme sensitivity pattern differs from the published patterns obtained from B- and T-cell leukaemias[9], but is identical to a pattern obtained with a transforming gene present in a fibrosarcoma and also in an embryonal rhabdomyosarcoma line[17]. In a subsequent study[8] by the same group this sarcoma-derived gene was cloned and identified as the N-*ras* gene.

Southern blot analysis was then used to determine whether the AML-derived transfection foci contained the N-*ras* gene as suggested by the restriction enzyme sensitivity experiment. The probe used was an *Eco*RI–*Sst*I subfragment from a cloned 8.8-kb *Eco*RI fragment[8] containing the 5′ region of the N-*ras* gene given by Alan Hall. With this probe, we detected an 8.8-kb *Eco*RI fragment in DNA from a primary focus (Fig. 2*b*) and from three secondary foci (Fig. 2*c–e*). In a fourth secondary focus (Fig. 2*f*), a hybridizing fragment in the 20-kb region, corresponding to the upper *Alu*-containing fragment in Fig. 1*f*, was detected. The slower mobility of this fragment is probably due to loss of one of the *Eco*RI sites flanking the 8.8-kb fragment brought about by DNA shearing required by the transfection protocol[18]. We conclude that the transforming gene present in AML bone marrow represents the N-*ras* gene, part of which can be detected in most transfection foci as an 8.8-kb *Eco*RI fragment. Consistent with this interpretation are the results of immunoprecipitation experiments by H. P. Senn using a monoclonal anti-p21 antibody which show that secondary foci contain elevated levels of a *ras* protein (data not shown).

Table 1 Primary and secondary transfection experiments

Source of DNA	Foci per no. of plates	Foci per μg DNA
a Primary transfection		
Calf thymus	1/6	0.004
AML bone marrow	42/20	0.056
b Secondary transfection		
Primary foci		
T82/73-9A1	22/6	0.100
T82/73-10/2	12/6	0.053
T82/73-11/1	37/4	0.247
T82/73-10/3	22/6	0.100

The patient under study was in good general condition; the only abnormal findings were a moderate hepato-splenomegaly, slightly enlarged lymph nodes and a small perirectal abscess. The white blood cell count was $62\times10^9\,l^{-1}$ (normal range $5–12\times10^9\,l^{-1}$); most cells were atypical myeloblasts. There was thrombocytopenia with a platelet count of $55\times10^9\,l^{-1}$ ($150–400\times10^9\,l^{-1}$) and an anaemia with 91 $g\,l^{-1}$ of haemoglobin ($120–140\,g\,l^{-1}$). The bone marrow was hypercellular with 68% atypical myeloblasts cytochemically positive for peroxidase and Sudan black, negative for Pas and nonspecific esterase. This, together with morphological criteria, established the diagnosis of acute myeloblastic leukaemia (AML), type M2 according to the FAB (French–American–British) classification[15]. No abnormal findings were detected by karyotype and chromosome banding analysis (H. J. Müller, data not shown). Bone marrow cells prepared by standard Ficoll centrifugation were lysed using 0.5% SDS in 100 mM NaCl, 10 mM EDTA, 10 mM Tris-HCl, *p*H 7.4, and digested with proteinase K. DNA was prepared by phenol and chloroform–isoamyl alcohol extractions followed by ethanol precipitation and subsequently resuspended in 10 mM Tris-HCl, *p*H 7.5, 1 mM EDTA. NIH 3T3 cells, seeded at 5×10^5 cells per 10-cm dish 1 day before the experiment, were transfected with 37.5 μg DNA as described[18]. Medium was changed 6 h later, then twice weekly. Foci of morphologically transformed cells were counted after 14 days.

0028–0836/84/050476–03$01.00

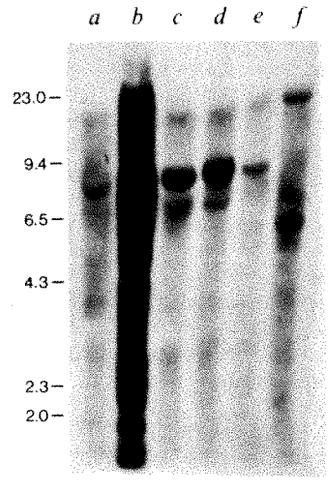

Fig. 1 Presence of human repetitive DNA in primary and secondary transfection foci. Aliquots (15 μg) of cellular DNA were digested overnight with *Eco*RI, phenol-extracted, ethanol-precipitated and subjected to agarose (0.8%) gel electrophoresis. After transfer of DNA to nitrocellulose, hybridization was done in the presence of 10% dextran sulphate at 67 °C using 2×10^7 c.p.m. of BLUR-8 probe[16] nick-translated to a specific activity of 1.4×10^8 c.p.m. per μg DNA. The final wash of the filter was in 0.5×SSC/0.1% SDS for 20 min at 65 °C. Autoradiography was at −70 °C for 16 h using Kodak X-Omat SO-282 and an intensifying screen. Cellular DNA was from: *a*, NIH 3T3 cells; *b*, primary focus T82/73-9Al; *c*, secondary focus T83/76-7b; *d*, secondary focus T83/76-9a; *e*, secondary focus T83/80-8; *f*, secondary focus T83/76-11a.

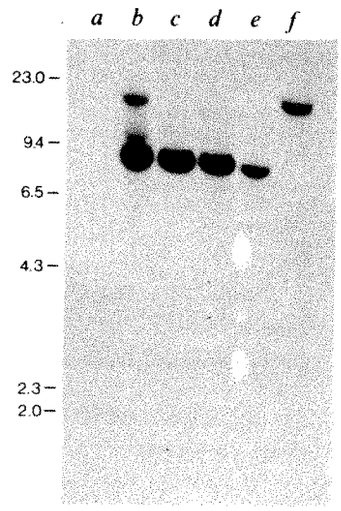

Fig. 2 Presence of the human N-*ras* sequence in primary and secondary transfection foci. Cellular DNA (15 μg) was digested overnight with *Eco*RI and a Southern blot performed as described in Fig. 1 legend except that the final wash was at 62 °C. The probe was an *Eco*RI–*Sst*I subfragment of the human N-*ras* 8.8-kb *Eco*RI fragment[9], nick-translated to a specific activity of 4×10^8 c.p.m. per μg of DNA. Cellular DNA was from: *a*, NIH 3T3 cells; *b*, primary focus; *c–f*, secondary foci as in Fig. 1.

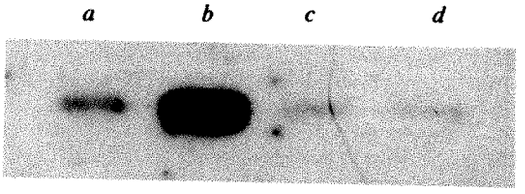

Fig. 3 Lack of *myc* gene amplification in AML DNA. Aliquots of cellular DNA (15 μg) were digested overnight with *Sst*I and a Southern blot was performed as described in Fig. 1 legend. The probe was pMC41-3RC, a 1.4-kb fragment[14] of the human *myc* gene cloned into pBR322. Specific activity was 5×10^8 c.p.m. per μg DNA. Cellular DNA was from: *a*, normal human spleen; *b*, human promyelocytic leukaemia HL-60; *c*, bone marrow from AML patient; *d*, fibroblasts derived from AML patient. The size of the fragment shown is 2.8 kb.

A transforming N-*ras* gene has been reported to be present in a neuroblastoma[7] line, two sarcoma[8,17] lines, the promyelocytic leukaemia[11] line HL-60, and, as presented here, in AML bone marrow cells at the outbreak of the acute phase of the disease. Thus, this gene is associated with tumours of different origins, but also with different maturation stages of leukaemias within the same lineage, namely the more primitive AML and the more differentiated promyelocytic leukaemia.

The HL-60 line has been shown to have an alteration of a second oncogene—an amplification of the *myc* gene[13,14] which is associated with chromosome translocations in human B-lymphomas[19–22]. While it is assumed but not known whether the N-*ras* gene was already present as a transforming variant in the original HL-60 tumour biopsy, it has been shown that the *myc* amplification had occurred *in vivo*[14]. To determine whether we could detect a *myc* gene alteration in AML DNA, we examined DNA from the original bone marrow aspirate and DNA from skin fibroblasts established in culture from the same patient. Normal human spleen DNA from an unrelated donor and DNA from HL-60 cells were included in the analysis as controls. As a probe we used a *Cla*I–*Eco*RI fragment of the human *myc* gene containing the 3′ exon given by R. C. Gallo. We detected neither amplification nor altered mobility of the *myc* gene in our AML patient, while HL-60 DNA showed the expected[13,14] amplification (Fig. 3). While we cannot exclude a minor *myc* gene alteration, it seems that N-*ras* activation in AML can occur independently of *myc* amplification/rearrangement. If indeed both the N-*ras* and *myc* genes have a role in the natural history of some myeloid leukaemias of which HL-60 may be a prototype, it would seem that in some cases, such as the more primitive AML, the activated N-*ras* gene exerts its effects independently of *myc*, and thus may require alterations of other genes.

To approach the question of whether the activation of the N-*ras* gene observed in this patient was a somatic event, we intend to compare the cloned activated gene with its alleles from the patient's fibroblasts. In three preliminary transfection experiments, this fibroblast DNA displayed a focus-forming activity of <0.005 foci per μg DNA, which corresponds to background values (compare Table 1). However, sequencing data from the cloned N-*ras* alleles will be needed to establish more firmly that N-*ras* activation in this patient was indeed a somatic event. It will be interesting to see whether this activation involves similar mutational events to those reported for the H-*ras* gene, namely a single base pair change altering either amino acid 12 (refs 23–25) or 61 (ref. 26) of the corresponding p21 protein. In addition, the present demonstration of an activated N-*ras* gene from an AML patient occurring in the absence of detectable *myc* gene alteration calls for an extensive study on the status of the N-*ras* gene and its expression in acute leukaemias.

We thank Drs R. A. Gallo and A. Hall for their gifts of DNA probes, and Dr J. A. Kop for critically reading the manuscript. We acknowledge the technical assistance of Ms Heide Luther and Mr Paul Hofer.

Three-dimensional structure of the light-harvesting chlorophyll *a*/*b*–protein complex

W. Kühlbrandt

Institut für Zellbiologie, ETH Hönggerberg, CH-8093 Zürich, Switzerland

Photosynthesis in the chloroplasts of green plants is carried out by a highly organized system of membranes. Chlorophyll–protein complexes in the photosynthetic membrane perform specialized functions which result in the biochemical fixation of solar energy. The light-harvesting chlorophyll *a*/*b* protein complex (LHC) has a key role in this process[1,2]. A striking property of the LHC that distinguishes it from other chlorophyll–protein complexes and makes it suitable for structural studies by Fourier methods is its tendency to form crystalline arrays *in vitro*[3]. I report here the three-dimensional structure of pea LHC determined at 16 Å resolution by electron microscopy of two-dimensional crystals and image analysis. A three-dimensional map shows that the LHC is a highly asymmetric transmembrane protein composed of three structurally equivalent monomers. The large surface area exposed on one side of the trimeric complex suggests a functional role in membrane interaction. The ability of LHC isolated from widely different plant species to form similar crystalline arrays[4–6] suggests that the structure reported here is of general significance.

Apart from its function as a molecular antenna that harve solar energy, the LHC regulates the transfer of excitation ener to the reaction centres of photosystems I and II, depending the phosphorylation of the LHC apoprotein[2]. The complex a mediates the interaction of thylakoid membranes which lea to the formation of stacks of apposed membrane vesicles, t chloroplast grana. This process is triggered by cations a resembles the formation of crystalline arrays *in vitro* whi occurs spontaneously on addition of cations to the detergei solubilized complex[7]. By controlled dialysis against moderz salt concentrations it is possible to obtain extensive, high ordered two-dimensional crystals of the LHC. These crystalli sheets have a hexagonal lattice with a 125 Å unit cell dimensio and belong to the P321 space group. They are composed interdigitating triangular units alternating in orientation to t plane of the sheet[4].

Specimens of crystalline sheets shadowed with heavy me to reveal their surface structure show a hexagonal array of ho ~90 Å in diameter (Fig. 1*a*). The holes span the tw dimensional crystal, indicating the absence of a continuous lip bilayer. The shadow cast in the holes and at the edges sho that the sheets are ~60 Å thick and therefore are single lay of molecules, an important prerequisite for this type of structu analysis. When contrasted with negative stain, the cryst resemble a honeycomb with the stain-excluding protein s rounding dark pools of contrasting agent within the ho (Fig. 1*b*).

Two-dimensional crystals contrasted with the negative sta uranyl acetate, were used to determine the three-dimensio structure of the LHC in a way similar to that described Henderson and Unwin[9]. This method takes advantage of t fact that the Fourier transform of an electron micrograph o two-dimensional crystal is a central section through the thr dimensional Fourier transform of the crystal, that is, throug lattice of lines in reciprocal space which are perpendicular the plane of the crystal. By combining the Fourier transfor of a sufficient number of different, tilted views it is thus possi to measure the amplitudes and phases of Fourier terms alo each lattice line. As in X-ray crystallography, an inverse Fou transform then yields a three-dimensional map of the structu In this analysis, amplitude and phase data were obtained computing the Fourier transforms of well-order densitometered areas of 43 electron micrographs of LHC cr tals tilted up to 82° in the electron microscope. Fourier te at the points of the reciprocal lattice (where the transform pl intersects the lattice lines) were collected and combined, us

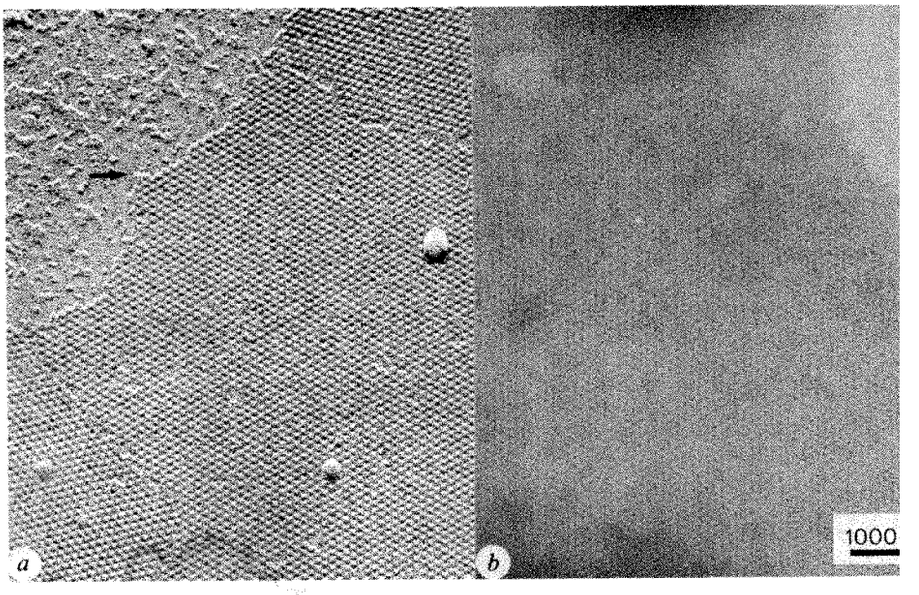

Fig. 1 Two-dimensional crystals of the LHC from pea chloroplasts: *a*, freeze-dried and shadowed with platinum at an angle of 45°; *b*, negatively stained with a 2% (w/v) uranyl acetate solution containing 0.1% (w/v) Triton X-100 (Sigma). The shadow cast at the edge of the crystalline sheet in *a* (arrow) indicates a thickness of 60 Å. The surface relief of the crystals shows a hexagonal array of holes measuring roughly 90 Å across which span the crystalline sheets. The holes appear as dark pools of stain in negatively contrasted sheets (*b*). The LHC was isolated from pea chloroplasts as described elsewhere[4]. KCl was added to the fluorescent density gradient fraction to a final concentration of 200 mM. The microcrystalline precipitate was pelleted after 3–4 min at room temperature and redissolved in 0.2% (w/v) unbuffered Triton X-100. Two-dimensional crystals were obtained by dialysis of the purified gradient fraction against 300 mM KCl, 10 mM Tris-HCl *p*H 6.9, 0.1% (w/v) Triton X-100 and 1 mM NaN_3 for ~1 h at 32–39 °C.

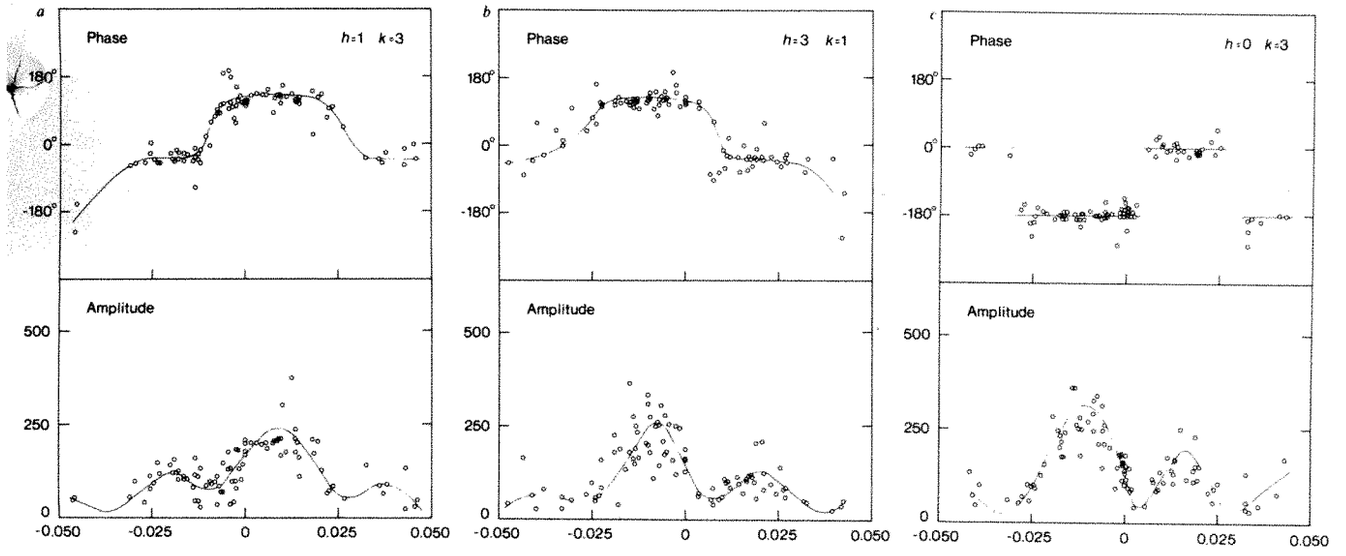

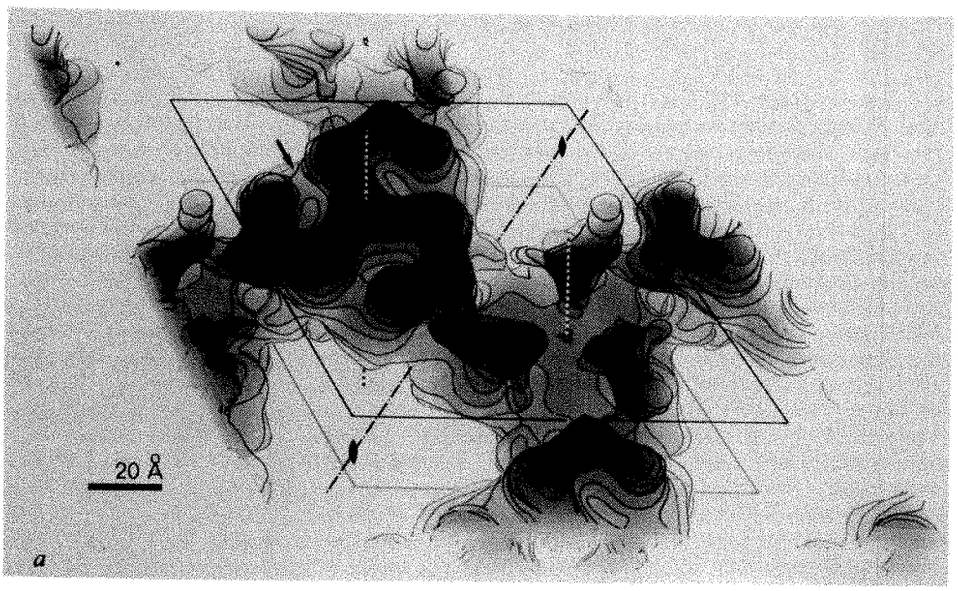

Fig. 2 Amplitude and phase of Fourier terms with Miller indices: *a*, $h = 1$, $h = 3$; *b*, $h = 3$, $k = 1$; and *c*, $h = 3$, $k = 0$ as a function of the reciprocal space coordinate, z^*. The apparent mutual mirror symmetry of pairs of lattice lines (h, k) and (k, h) (for example, *a* and *b*) and the real phase angles of 0° and 180° in the entire z^* range for axial lattice lines (for example *c*) indicate P321 symmetry. Data to a resolution of 16 Å were collected at reciprocal lattice points on computed Fourier transforms of 36 images in six tilt series of five negatively stained two-dimensional LHC crystals, with tilt angles ranging from 0° to 62°. Seven images of crystalline sheets recorded at tilt angles between 62° and 82° were incorporated in the final data set. Data were merged using the 3-fold symmetry of the two-dimensional crystals in projection. The phase residual averaged over all images with tilt angles <62° was 19.3° when no symmetry was imposed (P1 space group), 19.2° for P3, and 19.4° for P321 symmetry, confirming that the highest symmetry, P321, applied.

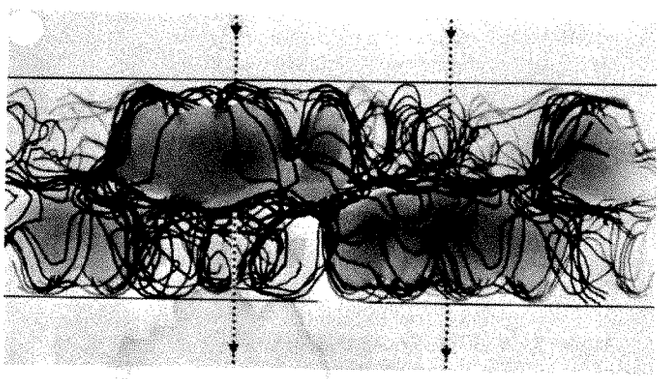

Fig. 3 Three-dimensional map of the LHC viewed from above (*a*) and edge-on (*b*) drawn to the same scale. The map shows two complexes in the unit cell. A 3-fold symmetry axis (· · · ·) runs centrally through each complex. The two trimeric LHC molecules are related by a 2-fold symmetry axis (·–·–·) so that adjacent complexes alternate in orientation perpendicular to the plane of the crystalline sheet. Different structural detail is exposed on the two external surfaces of the complex, which is a highly asymmetric, integral transmembrane protein. The edge-on view (*b*) in a direction perpendicular to the unit cell edge at the front of *a* indicates the vertical distribution of density within the complex. The main mass is found near the side of the complex which in the top view is characterized by three hook-like arms extending around three darkly staining gaps (arrow). The thickness of the LHC trimer and of the crystalline sheets is ~59 Å. The map was generated from structure factors sampled at regular intervals of 0.005 $Å^{-1}$ without imposing 2-fold symmetry. The distance between sections is 3.125 Å in the top view and 3.38 Å in the edge-on view. Contour lines were drawn at the first positive level of a linear 0 to 9 scale. Areas within the first (*a*) and third (*b*) contour level respectively are shown as opaque.

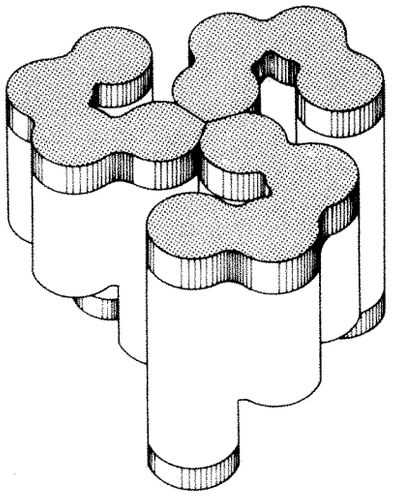

Fig. 4 Schematic drawing of one light-harvesting complex as it appears from the three-dimensional map (Fig. 3). The 3-fold symmetry of the complex indicates that it is a trimer, composed of three structurally equivalent subunits. The shaded regions show the part of the complex that would protrude from a hypothetical 45-Å lipid bilayer symmetrically positioned in the two-dimensional crystal. The platform at the top of the complex suggests a functional role in membrane interaction through van der Waals' forces between LHC molecules in stacked membranes.

the 3-fold symmetry of the crystals, to map out the variation of amplitudes and phases along the lattice lines (Fig. 2). The data extended to a resolution of 16 Å.

A three-dimensional map of the LHC (Fig. 3), generated from structure factors sampled at regular intervals along lattice lines, shows that there are two LHC molecules per unit cell (Fig. 3*a*). The two molecules are related by a 2-fold axis, a symmetry element of the crystalline sheets that form *in vitro*. In the native membrane, all LHC molecules face the same way up[10]. A 3-fold axis runs vertically through the centre of each complex, indicating that LHC is a trimer, composed of three subunits in symmetry-related positions. The trimeric nature of the complex has also been suggested by gel electrophoresis[11]. The two trimers in the unit cell represent the two main aspects of the complex as seen from above and below the plane of the crystalline sheet, respectively. Clearly, LHC is an asymmetric membrane protein, exposing different structural features on both sides. One side (termed the top side) shows three hook-shaped, somewhat angular lobes separated by stain-filled gaps that extend ~20 Å vertically into the complex (arrow in Fig. 3*a*). Each lobe appears to be composed of three vertically oriented, roughly cylindrical domains of 15–20 Å diameter, connected by narrower bridging regions as indicated in Fig. 4. The other side shows three oblong protrusions which are continuous with the hook-shaped lobes.

An edge-on view of the three-dimensional map (Fig. 3*b*) shows that the thickness of the crystalline sheet and of the LHC trimer is ~59 Å, which agrees well with measurements made on stacked sheets[4] and by heavy metal shadowing. Seen edge-on, the complex appears highly asymmetric. Roughly half way up the trimer there appears to be a change in density. The less dense region at the bottom of the complex is taken up by the three elongated protrusions. The dense region which accounts for 80% of the stain-excluding volume consists of the three hook-shaped lobes. The lobes appear to form a rigid platform at the top of the complex which presumably is exposed at the surface of the thylakoid membrane. Immunological studies[10] have shown that both sides of the complex protrude from the native membrane and expose different antigenic sites on the two membrane surfaces. Due to the absence of a continuous lipid or detergent bilayer in the two-dimensional crystals used here, the three-dimensional map does not show by how much the complex protrudes on the two sides, but, given a bilayer thickness of 45–50 Å (ref. 12), the LHC cannot protrude by more than 10–15 Å (see Fig. 4).

An effect of the pronounced asymmetry of the LHC is a large difference in surface area exposed on both sides. The area exposed on the top side is three or four times larger than that exposed on the opposite side, and roughly twice as large as that exposed by a cylindrical molecule of the same height and volume. It is suggested that the extensive platform at the top of the LHC molecules has a functional role in membrane interaction. The repeat distance of stacked sheets, 56–58 Å (ref. 4), shows that complexes in adjacent membranes can approach one another close enough for van der Waals' forces to take effect[13]. The flat top surface of the LHC molecules seems highly suited for this purpose. Another possible functional role of this part of the molecule is that of a scaffold for orienting and arranging the antenna chlorophylls to cover a large surface area. The three protrusions on the other side could serve to anchor the molecule in the membrane and to make contact with the chlorophyll–protein complexes of photosystem II which are closely associated with the LHC[14].

The purified pea LHC used in this study contains roughly equal amounts of two different, largely homologous polypeptides of 25,000 and 27,000 apparent molecular weight[4,15] which each bind chlorophyll *a* and *b*. The total number of chlorophyll molecules attached to one polypeptide is in dispute, with reported values ranging from 6 (ref. 16) to 11 (ref. 17). The polypeptide patterns of LHCs isolated from other sources are often more diverse, containing up to four different components in the same molecular weight range. The larger polypeptide of pea LHC has recently been sequenced, giving an exact molecular weight of 28,512 (ref. 18). An estimate of the stain-excluding volume of the trimer at the selected contour level gave a molecular weight of ~100,000, using a specific volume of 1.3 $Å^3$ per dalton derived from the density of bacteriorhodopsin[9]. Allowing for bound chlorophyll, this value suggests that the trimer is composed of three rather than six polypeptides. It seems, therefore, that the two different polypeptides found in pea LHC are structurally equivalent and interchangeable in the trimer, in a way similar to isoenzymes such as lactate dehydrogenase in which two different polypeptides combine to form tetramers of all possible permutations[19]. Evidence indicating that the different LHC polypeptides are products of a small multigene family[18] supports this view. LHCs isolated from widely different species such as spinach[5] and barley[6] have very similar properties and form crystalline arrays similar to those studied here. The structure reported here may therefore prove to be valid for the main antenna protein of all green plants.

I thank K. R. Leonard who made computer facilities and programs at the EMBL, Heidelberg, available to me. The data merging program was written by S. D. Fuller. I also thank O. Kübler for the use of image processing equipment and a two-dimensional Fourier transform routine, and T. Thaler for his assistance in isolating the complex. Part of this work was supported by an EMBO short-term fellowship.

Thermodynamics of the B–Z transition in superhelical DNA

Maxim D. Frank-Kamenetskii & Alexander V. Vologodskii

Institute of Molecular Genetics, Academy of Sciences of USSR, Moscow 123182, USSR

One of the most exciting events in recent years in molecular biology was the discovery of the left-handed Z form of the DNA double helix. Originally found in linear self-complementary $d(GC)_x \cdot d(GC)_x$ polymers[1] and oligomers[2] in non-physiological conditions (a rather high salt concentration), it was recently shown to be easily enough adopted in physiological conditions when purine–pyrimidine sequences are inserted into superhelical DNA[3–9]. From such a system, superhelical DNA carrying an artificial purine–pyrimidine insert, we can obtain data allowing the determination of the energy of the junction between the B and Z stretches, F_j, and the free energy change ΔF_{BZ} per base pair (bp). We present here a simple thermodynamic consideration of the B–Z transition in such a system. By applying the results to experimental data[3–9] we have shown that the thermodynamic parameters for both sequences studied so far ($d(GC)_x \cdot d(GC)_x$ and $d(GT)_x \cdot d(AC)_x$) are similar and equal to $F_j = 4$–5 kcal per mol per junction and $\Delta F_{BZ} = 0.5 \div 0.7$ kcal per mol per bp.

We consider closed circular DNA, N bp long, carrying an insert of n bp which is potentially capable of adopting the Z conformation, that is, sequences such as $d(GC)_x \cdot d(GC)_x$, $d(GT)_x \cdot d(AC)_x$, and so on.

Note that by n we denote the total number of bp in the insert, that is, $n = 2x$.

Generally speaking, we have to allow for the B–Z transition in our statistical-mechanical treatment of superhelical DNA along with open regions and cruciform structures[10–13] because all these alterations of the B form compete for the superhelix energy. We do that elsewhere[14]. Here we present a simple thermodynamic treatment based on the assumption that DNA may experience only the B–Z transition in its artificial purine–pyrimidine insert.

As the negative superhelicity increases, the insert adopts the Z form. In general, this process consists of two stages. At the first stage some fraction of the insert, m_0 bp long, flips from the B to Z form at some superhelix density value σ_0. Then, if $m_0 < n$, the rest of the base pairs in the insert would adopt the Z conformation gradually as the negative superhelix density increases further. The flipping occurs when the free energy increase due to the formation of the m-bp Z-form fragment is balanced by the energy decrease due to the relaxation of the strain in the superhelical DNA:

$$2F_j^* + m\Delta F_{BZ} + \Delta G_m = 0 \qquad (1)$$

Here F_j^* is the effective energy of the junction between B and Z forms, ΔF_{BZ} is the free energy change per bp for the B–Z transition. ΔG_m is the change in superhelix energy when m bp are converted from the B to Z form, which is known to be[5,15,16]:

$$\Delta G_m = 10RTN\left[\left(\sigma + \frac{1.8m}{N}\right)^2 - \sigma^2\right] \qquad (2)$$

Here σ is the titratable superhelix density value in DNA, and the factor 1.8 appears because the number of bp per helical turn is assumed to be 10.5 in the B form and 12 in the Z form[2,5]. Substituting equation (2) into equation (1) we obtain:

$$32.4RTm^2 + mN(\Delta F_{BZ} + 36RT\sigma) + 2NF_j^* = 0 \qquad (3)$$

The minimal value of $-\sigma$ for which equation (3) has a real root with respect to m defines the superhelix density of flipping, σ_0. This value is determined by setting the discriminant of quadratic equation (3) at zero, leading to:

$$\sigma_0 = -\frac{1}{36RT}\left(\Delta F_{BZ} + 11.4\sqrt{\frac{2F_j^* RT}{N}}\right) \qquad (4)$$

The number of bp that flip at this superhelix density:

$$m_0 = 0.175\sqrt{\frac{2F_j^* N}{RT}} \qquad (5)$$

Equations (4) and (5) are valid only if $m_0 < n$. If they lead to an m_0 value larger than n it means that the whole insert flips to the Z form at some value, σ_n, ($|\sigma_n| > |\sigma_0|$) and this value is determined by equation (3) with m replaced by n. In the case of $m_0 < n$ the flipping is followed by a gradual growth of the Z form stretch with increasing negative superhelicity. For m values within the interval $m_0 < m \leq n$ the following equation holds:

$$\Delta F_{BZ} + 36RT\left(\sigma + 1.8\frac{m}{N}\right) = 0 \qquad (6)$$

Equation (6) reflects the fact that the energy increase due to the transition of a base pair from the B to Z form should be balanced by the energy decrease due to the decrease of the superhelix strain. Equation (6) shows that

$$\sigma + 1.8\frac{m}{N} = \text{const. for } m_0 < m \leq n \qquad (7)$$

Before comparing the results with experimental data we must emphasize that our treatment was oversimplified in one important point. We have neglected the entropic terms that originate from the fact that a number of states with the same or almost the same energy correspond to a given value of m (when $m < n$). Most probably all positions of the originally flipping stretch of m_0 bp are energetically equivalent while it is within the n-bp insert. We have performed rigorous calculations based on the partition function. The complete results will be presented at length elsewhere[14]. The general situation has proved to be rather complicated. It is simple if m_0 is small compared with n, in which case the above equations remain valid with

$$F_j^* = F_j + \Delta \qquad (8)$$

The value of Δ is a weak function of the parameters and may be considered as a constant $\Delta = -1.8$ kcal per mol. When $m_0 \geq n$, the entropic terms may be practically neglected, that is, $F_j^* = F_j$.

Turning to the experimental situation, we see that both behaviours predicted by the above theoretical analysis were really observed. In most cases the insert flipped as a whole[3–7] but Haniford and Pulleyblank[8] have recently observed the flipping of a part of the insert followed by the elongation of the Z form stretch with increasing negative superhelix density.

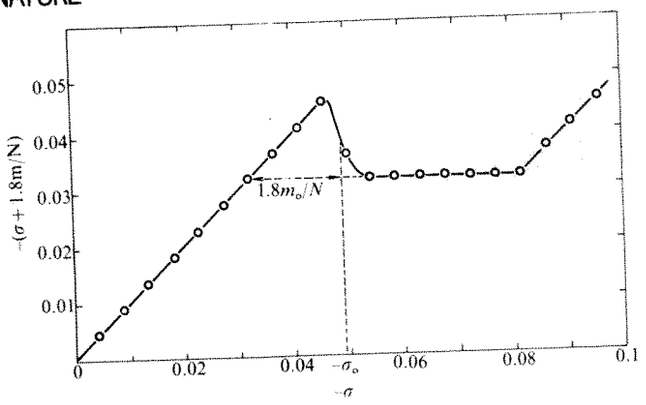

Fig. 1 The data of Haniford and Pulleyblank[8] presented in a form suitable for theoretical analysis. The value $\sigma + 1.8m/N$ is determined directly from the scaled experimental value of DNA mobility in gel. The value of σ_0 corresponds to the middle point in the flipping of the m_0-bp stretch.

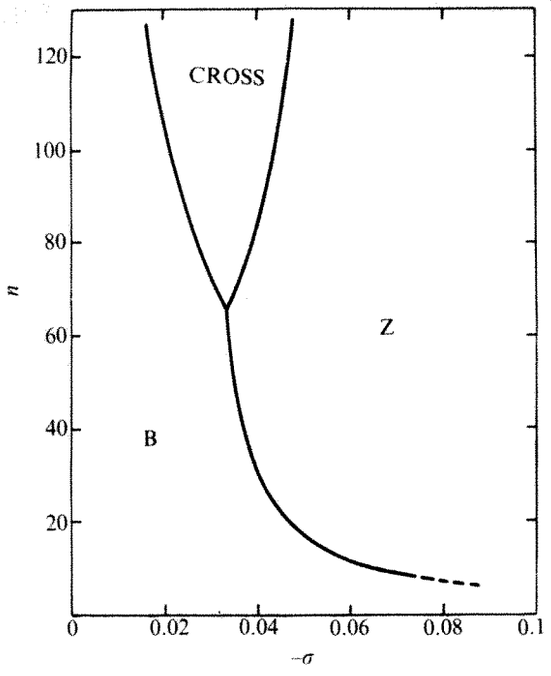

Fig. 2 Phase diagram for an n-bp $d(GC)_x \cdot d(GC)_x$ sequence inserted into long superhelical DNA with superhelix density σ. The calculations have been performed for $F_j = 4.0$, $\Delta F_{BZ}^{GC} = 0.6$, $F_s = 6$ and $\Delta F^{GC} = 2.1$ kcal per mol corresponding to 0.2 M Na^+.

In their experiments the $d(GT)_{30} \cdot d(AC)_{30}$ sequence was inserted into a plasmid with $N = 2.2 \times 10^3$ and at $\sigma_0 = -0.050$ $m_0 = 22$ bp flipped into the Z form[8]. Then the writhing number remained unchanged until the whole insert adopted the Z conformation. During this stage $\sigma + 1.8m/N = -0.032$ (Fig. 1). Using equations (5) and (6) and the above data, $F_j^* = 2.2$ kcal per mol for junction and $\Delta F_{BZ} = 0.69$ kcal per mol per bp. Substituting these values into eq. (4) we see that they give the observed value of σ_0. It follows from equation (8) that $F_j =$ 4.0 kcal per mol per junction. Since the $-\sigma_0$ value is rather low, the competition with cruciform structures can be neglected. This follows from the control two-dimensional gel electrophoresis pattern in[8] which shows no discontinuity up to the $-\sigma_0$ value. A cruciform structure would certainly have produced a clear-cut discontinuity in the two-dimensional pattern[17].

Equation (5) shows that an insert would flip as a whole if

$$n \leq 0.175 \left(\frac{2F_j N}{RT}\right)^{1/2} \tag{9}$$

For the most popular plasmid pBR322 ($N = 4.4 \times 10^3$) we conclude, substituting the above value of $F_j = 4.0$ kcal, that the insert would flip as a whole up to $n \approx 40$ bp. This estimate makes it quite clear why most people observed the flipping of whole inserts[3–7]. To interpret their data one has to use equation (3) in which m is replaced by n. This equation is similar to the one used by Nordheim *et al.*[5]

It follows from equation (3) that measuring the superhelix density values σ_1 and σ_2 of the B–Z transition for two inserts with lengths n_1 and n_2 one may determine the parameters:

$$F_j = 18RT\left[\sigma_2 - \sigma_1 + \frac{0.9}{N}(n_2 - n_1)\right]\left(\frac{1}{n_1} - \frac{1}{n_2}\right)^{-1} \tag{10}$$

$$\Delta F_{BZ} = 36RT\left[\frac{n_1\sigma_1 - n_2\sigma_2}{n_2 - n_1} - \frac{0.9(n_1 + n_2)}{N}\right] \tag{11}$$

Substituting the experimental values[5] ($n_1 = 14$, $n_2 = 32$, $\sigma_1 = -0.072$, $\sigma_2 = -0.048$) into equation (10) we obtain $F_j = 7.5$ kcal per mol in agreement with the original paper[5] but contradicting the above estimation. This may be explained by cruciform formation in the carrier pBR322 DNA between superhelix densities σ_1 and σ_2. Indeed, Singleton[18] has recently shown that in pBR322 DNA a 35 bp palindrome with the centre in position 3,065 assumes a cruciform. If in the conditions described by Nordheim *et al.*[5] it is formed within the superhelix density interval $\sigma_1 < \sigma < \sigma_2$ then we should replace in equations (10) and (11) the σ_1 value by the value $\sigma_1^* = \sigma_1 + n_+/N$ (n_+ is the number of bp in the palindrome[13]), then $\sigma_1^* = -0.064$ and equations (10) and (11) yield the values $F_j = 5.3$ kcal per mol and $\Delta F_{BZ} = 0.56$ kcal per mol. This example shows that the behaviour of comparatively short inserts that flip at high negative superhelix densities may be seriously affected by the cruciform formation in the carrier DNA[14].

The remaining difference between the values of parameters obtained for $d(GC)_x \cdot d(GC)_x$ and $d(GT)_x d(AC)_x$ inserts can hardly be regarded as significant and most probably reflects the accuracy of our present-day knowledge of the parameters. Other estimations of the same parameters have very recently led to quite similar results[19,20].

Having the parameters of the B–Z transition, we can predict the behaviour of a purine–pyrimidine insert for different n. If the sequence of the insert is not self-complementary, the behaviour is governed by the above equations. However, a self-complementary sequence (such as $d(GC)_x \cdot d(GC)_x$) can adopt a cruciform structure as well as a Z form. So in this case we have to consider the equilibrium between three possible states: the B form, the Z form, and the cruciform. For the sake of simplicity we will assume that N is very large and as a result m_0 is larger than n for all values of n under consideration. The free energies of the insert's transition from the B to Z form and from the B form to the cruciform are

$$F_z = n(\Delta F_{BZ} + 36RT\sigma) + 2F_j \tag{12}$$

$$F_+ = 20RTn\sigma + 3F_s + 4\Delta F^{GC} \tag{13}$$

Equation (12) immediately follows from equation (3) at $N \to \infty$. In equation (13) the last two terms are the energy of the cruciform formation, that is, the energy of six helix ends, and the energy of the formation of two single-stranded loops comprising four nucleotides each[10,11,13]. Using equations (12) and (13) we obtain the phase diagram plotted in Fig. 2. The diagram shows that small n values are not favourable for a cruciform structure. However, for n larger than 70 there is an interval of superhelix densities where a cruciform structure proves to be the most stable conformation. This interval grows as n increases.

Note that this behaviour may be difficult to observe because of the very large relaxation time, especially for the cruciforms[17,21].

Anatomy of higher education

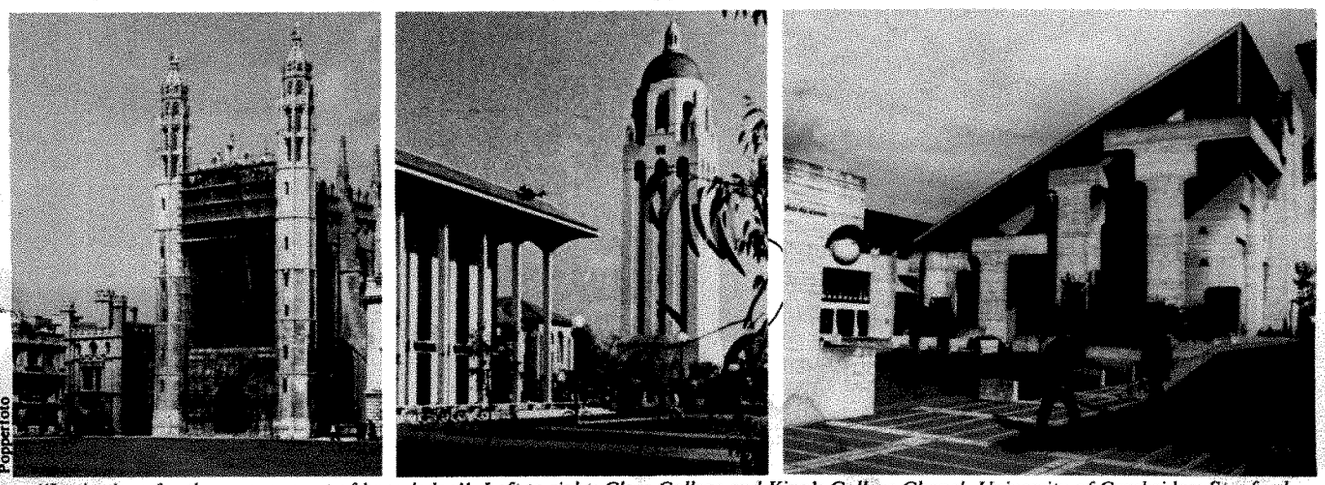
Eric Ashby

The Higher Education System: Academic Organization in Cross-National Perspective. By Burton R. Clark.
University of California Press: 1983. Pp.315. £21.25, $32.50.

TO SET this book in perspective, here are three incidents from my own experience.

First, dinner at high table in the University College of the Gold Coast (now Ghana) in 1956. The students, wearing gowns, stand as we file in: the master, the senior tutor, the steward, the chaplain. A Latin grace is read. After dinner we retire to the Combination Room and are offered port. The terms, in a nation with a large Muslim and pagan population, were labelled Michaelmas, Lent and Trinity. The purchasing officer was called a manciple.

Second, a faculty discussion in Lovanium University in what was, in the 1950s, the Belgian Congo. Or, to be accurate, a briefing, not a discussion, for the rector was a Napoleonic figure unconcerned with the niceties of democracy. He was appointed from Louvain and was in direct teletype contact with Belgium from his office in Leopoldville. The number of Congolese graduates at that time was pathetically small for a country about to become independent. What curriculum (I asked) had they devised in order to prepare the Congolese to administer their affairs. Exactly as in Louvain, was the reply: a basic course in philosophy, French language and French literature before qualifying for any professional training; *Chanson de Roland* in the first year.



Third, a visit to the University of Nigeria in Nsukka, created in the early 1960s under the sponsorship of Michigan State University. As you come from Enugu you see the university spread below you, on a flat plain below a steep hill, with the central, predominant feature of a sports stadium. The cafeteria, I found, was crowded with somewhat subdued and perplexed farmers from the surrounding villages, attending a week-end course in poultry nutrition.

These were just the superficial signs of the genetic imprint of Cambridge on Ghana, Louvain on the Congo and Michigan on Nigeria. It permeated curriculum, style of administration, academic values. At first there was scant evidence of adaptation to the local society. This deep imprint of older universities on newer ones is not just a recent phenomenon. In 1551 the Spanish emperor Charles V founded universities in Mexico and Peru with all "the privileges, exemptions, and limitations of the University of Salamanca". Even the order of precedence in the academic procession and the exact procedure at convocations had to be prescribed from Salamanca. In Scottish universities there is a vestige of inheritance from Bologna, when the students elect the Rector. In Cambridge, candidates for the bachelor's degree are presented to the vice-chancellor with the assurance (fortunately delivered in Latin) that they have satisfied their teachers in morality as well as in learning. For centuries the university, like church and parliament, has shown extraordinary resilience and capacity for adaptation — surely a challenge to scholars to analyse how this has happened. Yet, despite shelf-loads of rhetoric about "the Idea of a University" and some good historical accounts of universities in separate countries, very few scholars have risen to it. Burton Clark is one of them. This alone makes his book an important one.

The easy way to approach the task is to describe, seriatim, the systems of higher education in different countries and then in a final chapter to apply the formula familiar to examinees — "compare and contrast". The result is rarely illuminating and invariably dull. Clark meets the challenge in a more ambitious way. What, he asks, are universities *for*? What do they believe about themselves and what does the so called "layman" (that word is historically significant too) think about them? Where does authority lie in systems of higher education? They have changed over the centuries and by implantation into alien cultures: what have been the incentives, and what have been the impediments, to change?

The raw material for universities is knowledge. They are, Clark declares, institutions for the management of knowledge; research and teaching are the technologies employed in management. But knowledge is not homogeneous. An institution for the management of knowledge brings on to one campus mediaevalists, biochemists, engineers. Why? Mediaevalists can get on perfectly well without biochemists. Are they together simply to share the central heating system and the catering facilities? In the Soviet system much professional education is in staff colleges attached to the appropriate ministries: lawyers in a college run by the ministry of justice, doctors in a college run by the ministry of health. Yet an institution embracing many diverse disciplines remains the standard pattern for higher education.

Clark's painstaking analysis of this question holds no surprises for anyone who has spent a lifetime in academe, but it includes a great deal that is not understood by the politicians and bureaucrats who now have such influence over the future of higher education. He explains how it is much more than basic facilities that bring scholars together into universities. They share certain beliefs; they have common problems of divided loyalty; they cannot work well unless they are allowed to devise for themselves a very peculiar structure of

"Institutions for the management of knowledge". Left to right: Clare College and King's College Chapel, University of Cambridge; Stanford University and the Université Catholique de Louvain

power and authority, one in which the process of decision-making does not descend in decrees from above but arises on the "shop floor" and percolates upwards, to reach (paradoxically) the desk of the individual who, *de jure*, is the boss of the institution. Prominent among the beliefs is a common purpose: to transmit, by teaching, the orthodoxy of the discipline and to generate, by research, a rigorously controlled system of dissent from orthodoxy. There is a mystique about this and there is intense loyalty to an institution that nurtures this mystique. But these communities of scholars have to come to terms with two often conflicting loyalties. On one hand their loyalty is to the discipline: what matters most to a physicist may be his status among other physicists, and this tempts him to put what he calls "my own work" before the interests of the university in which he serves. On the other hand their loyalty is to the institution and its corporate interests: what matters most may be the educational mission of the community, to produce (as the Oxford don, Mark Pattison, put it) "not a book but a man". "The culture of a discipline even includes idols", writes Clark. In the sociologist's office you see a picture of Max Weber on the wall. Yes, and in the office of a chemist who is also a tutor or a dean you see a picture of Magdalen quadrangle on the wall. It is symbolic of the split-personality that inhabits the academic mind. There are subtle differences among different countries in the emphasis given to these loyalties. An American would talk of belonging to the Yale Class of '24; a German would not state his university, but would say "I was a pupil of Heisenberg"; a graduate from Oxbridge does not even mention his university: he is called "a Clare man" or "a Wadham man".

An institution for the management of knowledge has to solve a very difficult problem in the management of its own members. The scholars are differentiated into dozens of disciplines and sub-disciplines. Those in authority over them cannot possibly tell them what to do; yet someone has to allocate space, cut the financial cake into slices, provide the common services. And someone has to defend the university's interests against pressures from what is (shortsightedly) called "the outside world". Clark describes in detail the patterns of academic authority: the dictatorial professor who has the right of patronage (as is to be found in Italy); the collective control by committees of academics (as is to be found in Britain); the administrators who manage the university as a sort of holding company for semi-autonomous oligarchies of faculties or colleges (as in California); the limited delegated control under a system managed by the state, where the professors are civil servants (as in France). He sees good and bad in all these patterns and wisely refrains from committing himself to preferences among them.

Finally, Clark discusses change in institutions of higher education. Here, it seems, is another paradox: that they are notoriously the most exasperatingly conservative bodies and yet it is from them that the most revolutionary initiatives for changes in society come. Clark finds this puzzling, but I think the explanation may be quite simple. It is that the initiatives come from the "shop floor", from the research and writing of young people. The resistance comes from the people who have become enmeshed in the administrative network of the place or whose interests would be endangered by change. The obduracy of the University of London to reform itself is a local British example of this.

Clark's book is written with authority but I must add a warning that his conclusions are at a level of generalization which I found at times hard to follow. I am not a sociologist, so it is not for me to carp about the use of abstract latinized words which to the uninitiated may seem to be jargon. In writing this "layman's" review of it, I may have oversimplified some of Clark's subtle reasoning, but I hope I have made it clear that this is a book which, even if it isn't to be read for pleasure, is certainly to be studied for profit. □

Lord Ashby is a Fellow of Clare College, Cambridge, and has been a professor in the Universities of Sydney and Manchester, and vice-chancellor in the Universities of Queen's, Belfast, and Cambridge.

Surface Physics

Dr J.E. Inglesfield asks us to point out that the title to his review of M. Prutton's *Surface Physics*, 2nd Edn (*Nature* **307**, 190; 1984) was chosen not by him but in the *Nature* office. No slight upon the book was intended by the title "Superficial science".

Editor, *Nature*.

Archaeology, A to Z

Colin Platt

The Macmillan Dictionary of Archaeology.
Edited by Ruth D. Whitehouse.
Macmillan, London: 1983. Pp.597. £25.

THE emergence of archaeology as an amalgam of several disciplines has been comparatively recent, dating back scarcely further than the 1960s. And it is this crossing of boundaries, still bewildering to many, that is the chief justification for Dr Whitehouse's new *Dictionary*. Handsomely presented in a generous layout, it has the enticing feel of a good work of reference: essential, of course, for instant instruction, but as well suited for a pleasurable browse. How many of us would have been aware, without such aid, that the earliest phase of the North Vietnamese Bronze Age is known to its students as "Go Bong"? On the very same page, we are cross-referred away from Gogo Falls, and are given a good, short account of the goat. Here is pleasure, stimulus and intelligence, all in one.

Nobody need have misgivings about the intended scope of this dictionary. Its field is the wide world; its timespan is four million years; its concern is with techniques as well as evidence. Nevertheless, what precisely were the principles, we are still bound to ask, that guided Ruth Whitehouse and her small team of subject editors in their selection of material for discussion in these pages? In the little she tells us on this fundamental matter, Dr Whitehouse is not reassuring. "I cannot claim", she confesses, "that coverage is even. . . . My own prejudices, and to a lesser extent those of my subject editors, have necessarily prevailed." One of these prejudices — perhaps a considered principle, though we are not so informed — is that the best archaeologist is necessarily a dead one. Thus David Clarke (d.1976), as one of the pioneers of the New Archaeology which itself gives purpose to this book, gets his entry. But Lewis Binford, very much more influential in the same field as Clarke precisely because he remains alive and active, does not. The editors have been spared embarrassing decisions, but only to the impoverishment of their text.

In the same way, other omissions would have been easier to accept if more trouble had been taken to explain them. Of course, this is a familiar game among critics of dictionaries, but so much the more reason to anticipate it. Why Repton and not Deerhurst? Why Krak des Chevaliers and not Sahyun? Why San Vincenzo al Volturno and not Monte Cassino? In each case, the answer seems to be that there have been excavations (or research programmes) on these sites known personally to one of the subject editors of this volume. And increasingly, as we come to follow through our individual specialisms, the *Macmillan Dictionary of Archaeology* begins to look narrowly based. Why, to go back to the general editor's opening apologia, do the compilers' prejudices, in a work of reference of this kind, "necessarily" have to prevail? They are a clannish group in which marital pairings and former scholarly cooperations are prominent. Could it be that there were just not enough of them from the start?

Fortunately, the preoccupations of Ruth Whitehouse's "team of international experts" are very likely to be those of the great mass of users of this dictionary. Nor is there any doubt that there is much of real value in these pages, clearly and professionally expressed. Mutton dressed as lamb, perhaps. But still good food. □

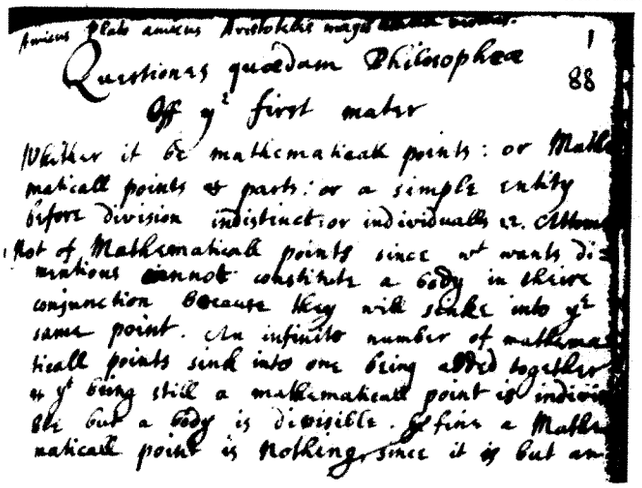
Newton of promise

C.W. Kilmister

Certain Philosophical Questions: Newton's Trinity Notebook.
By J.E. McGuire and Martin Tamny.
Cambridge University Press: 1983. Pp.519. £50, $84.50.



WE now know a great deal more about Newton than we did 30 years ago; this is mainly the result of Whiteside's magnificent edition of the papers, with the Halls' collection of the letters coming a close second*. As a result we can see the mistakes as well as the triumphs of a genius, and insights that, for one reason or another, never saw the light of day.

But are we any nearer to understanding this most astonishing of men? Perhaps a little, but because there is still so much left to understand one should hesitate long before relegating a work such as this to the "Newton's laundry book" category. And indeed such a judgement would be wholly unjust. In 1661, at the age of 18, Newton began to keep notes about his studies in Cambridge in a notebook which is in the University Library. But the *Questiones quaedam philosophicae* are (English) notes well on in the book and so almost certainly date from late March 1664 to late 1665. Since 1666 was to be, by his own confession, Newton's *annus mirabilis,* these notes on scientific matters could not fail to be of interest.

The book has been produced with all the care that American scholarship can provide, and the finished work is one of considerable beauty. Two-thirds of it is taken up by an essay describing the *Questiones* in the context of Newton's thought and of other thought of the time, and the remaining third presents, on facing pages, the transcription of the notebook and a modern English version (in which even Newton's sketches are carefully redrawn). So there is something for everyone. The historian and scholar have an important source presented in meticulous detail. The scientist can read the modern English and see Newton grappling with a variety of questions, some a consequence of the theoretical background with which he had been saddled by his university course, some of a much more modern kind.

He begins with a discussion of atomism and the "first matter", concluding that there must be atoms, finite in magnitude, and that as a consequence the "world" (i.e. the Universe) must be composed of a finite number of them, since "an infinite number of finite parts cannot be finite". This discussion partakes of an Aristotelian flavour in the arguments rejecting the possibilities of mathematical points serving as atoms. And Newton goes on to infer that, to discuss motion, there must be

> a least distance, a least progression in motion, and a least degree of time. Lay two globes together so close that they cannot come any nearer without touching — that is the least distance. Let them be moved together — that is the least degree of motion and it is performed in the least part of time.

Questiones quaedam Philosophicæ
Of y^e first matter
88
Whether it be mathematicall points: or Mathematicall points & parts: or a simple entity before division indistinct: or individualls &c. Not of Mathematicall points since ye wants dimensions cannot constitute a body in their conjunction because they will shake into y^e same point. An infinite number of mathematicall points sink into one being added together & y^t being still a mathematicall point is indivisible but a body is divisible. Ergo a Mathematicall point is nothing, since it is but an

In his own hand — the title page of the "Questiones", consisting of Newton's notes on Walter Charleton's consideration of the nature of first matter in "Physiologia Epicuro-Gassendo-Charltoniana".

So here was someone still far from understanding the use, let alone the nature, of fluxion or fluent, but at the same time preparing the ground for the seed. He returns to such problems later, evidently still worried, but without resolving them. This really summarizes the character of the whole book.

The next discussion is of the Sun, stars and planets: "Whether the Sun moves the vortex about (as Descartes's will) by his beams. . . . How it is that the Sun turns on his axis". Then a quotation "Hebrews, Chapter 1, Verse 2, God made the worlds by his son . . ." is followed shortly after by "On Saturday, December 10, 1664, by a subtle observation I found the distance of a comet from the centre of the Moon to be 9° 48′ . . .".

The properties of matter take Newton's attention next, including rarity, density, perspicuity, opacity, gravity and levity. He notes that "the matter causing gravity must pass through all the pores of a body". This is followed by a detailed discussion of the behaviour of this matter as it streams down to the Earth and back again. Then, quite soon, "you may observe in water that a thing moved in it does carry along with it the water behind it, as in a cone, or at least the water is moved from behind it with but a small force . . .".

There follows a varied selection of queries — on reflection of light, on atmospheric pressure, "What angle ought a windmill sail make with the wind", on water and salt, on magnetic attraction and electrical attraction, and so to much more on light, vision and colours. Even questions of memory, imagination and sympathy are touched on, succeeded almost at once by consideration of the character of oils, meteors, minerals and the tides. Here, as well as theoretical aspects of the vortex theory, there are notes about the reversing of the tides between Harris and Uist and about the alleged difference in speed of the Danube "as is perceived by the motion and noise of the clackers in mills" between six and midnight though "there is no ebb nor flow, the water keeping at a constant height".

Ever and again violent motion and motion itself return. Newton asks "Whether there can be motion in a vacuum" (since an earlier discussion interpreted the relative character of motion very strictly in terms of adjacent bodies). The argument concludes "If this going of c to d be not motion I ask what it is. But this is only to strive about terms, and if it pleases you not to call it motion call it what you will, but it is that which we aimed to prove". There are many astronomical observations and discussions, mostly of comets, before a return to motion yet again and then more optics. So it goes on, with notes on God and the soul, before various chemical queries come all together — genuine chemistry rather than alchemy, such as: "Alcalizate salts are wont to precipitate what acid salts dissolve".

So where does the notebook show us Newton standing? We see a man with at least part of one foot still in the Middle Ages, still needing to liberate himself from the weakening clutch of Aristotle; a man who has studied Descartes and is evidently not too happy about vortices. But above all we discern an enquiring mind, compulsively interested in everything around him or reported to him. In some ways a more human figure emerges. The authors tell us that "Newton's copy of Diogenes is extensively dog-eared . . . . As Newton used the technique of dog-earing, a dog-ear was used not only to mark a page but often to mark a place on a page". But the mystery is still there. The author of the notebook is the young man of promise. The Newton of 1666 still seems a different person. □

Experiments in the gauge revolution

C.H. Llewellyn Smith

Weak Interactions of Leptons and Quarks.
By E.D. Commins and P.H. Bucksbaum.
Cambridge University Press: 1983. Pp.473. Hbk £37.50, $69.50; pbk £16.50, $27.95.

FOLLOWING the discovery of parity violation in β decay in 1957, it was soon found that a wide range of "weak" decay processes can be described by a simple "phenomenological" theory. The pejorative adjective indicates that this theory is not mathematically consistent and can only work in a limited energy domain. In 1971, 't Hooft showed that consistency could be obtained in gauge theories of the type discussed earlier by Weinberg, Salam, Glashow and others, which have the great attraction of unifying weak and electromagnetic interactions. There was then no experimental evidence for such theories but their revolutionary potential was sufficient to stem the flow of books on weak interactions which had appeared during the 1960s.

Confidence in gauge theories built up as their predictions were gradually confirmed, beginning with the discovery of "neutral current" neutrino interactions at CERN in 1973 and culminating in the discovery of the W and Z bosons — the carriers of the weak force — with the predicted masses at CERN last year. Reflecting these developments, textbooks which incorporate or describe the "gauge revolution" have begun to appear in the past few years. This one, which is suitable for graduate students or as a reference work for researchers, is the first of the new generation of books written from an experimental standpoint in which crucial experiments are described. As well as the traditional topics, there are chapters on most of the subjects which ought now to be in such books — high-energy neutrino interactions, neutrino masses and oscillations, parity non-conservation in eN and NN interactions (including in atoms — the authors' speciality) and neutrinos in astrophysics.

Turning to omissions, it is odd that there is no derivation — or even statement — of the Fierz transformation, although it is frequently used. The omission of a proper discussion of current algebra and chiral symmetry is more serious. The Adler–Weisberger and Goldberger–Treiman relations appear (although the latter is confused with pole dominance of the pseudo-scalar form factor and we are not told whether the real relation works). Discussion of the Callan–Treiman relation and predictions for slope parameters in K $\rightarrow 3\pi$ surely also deserved some space. On the other hand, the "abbreviated and superficial" discussion of path integrals will help neither the novice nor the expert and could have been left out. The authors nowhere really use or need the full Feynman rules which they derive using this technique (although some discussion of testable higher-order predictions of gauge theories might have been desirable).

A more serious criticism is that the book contains several theoretical remarks which are dubious or misleading. Two of the more subtle examples must suffice. It is not true that Lagrangians "satisfy the Euler Lagrange equations" or that current conservation is in general equivalent to invariance of the Lagrangian (the whole question of auxiliary fields in supersymmetry bears witness to this). The mass-matrix for the K^0–$\bar{K}^0$ system does not follow from the Schrödinger equation given (although the appearance of the word "effective" perhaps provides an alibi) — a derivation involves the Wigner–Weisskopf theory of decaying states. A final point is that it seems perverse in a book largely devoted to interactions of neutrinos to normalize spinors in a way which is singular for massless particles.

Despite its faults, this is not a bad book. There are better introductions to gauge theories, such as *Gauge Theories in Particle Physics* by I.J.R. Aitchison and A.J.G. Hey (Adam Hilger, 1982), and clearer discussions of the phenomenology of weak interactions, for example in L.B. Okun's *Leptons and Quarks* (North-Holland, 1982) or T.D. Lee's monumental *Particle Physics and Introduction to Field Theory* (Harwood, 1981). However, this is the only up-to-date book on weak interactions which includes a discussion of the experiments and the data, and I would therefore advise students to read it and librarians to buy it. □

C.H. Llewellyn Smith is a Reader in the Department of Theoretical Physics, University of Oxford.

Exciting stuff

Principles of Fluorescence Spectroscopy.
By Joseph R. Lakowicz.
Plenum: 1983. Pp.496. $32.50, £25.

EVEN the most cursory glance over the literature of biochemistry, biotechnology and clinical medicine confirms the continuing growth in the exploitation of fluorescence techniques. How then should uninitiated researchers equip themselves to join the enlightened throng? Only the most dedicated can afford the time necessary to gain experience in a recognized "fluorescence" laboratory. More ordinary mortals have recourse to reading reviews, specialized articles and older classic books and papers selected from a large and diffuse literature. This can be a hard, unrewarding slog for the newcomer, and there has long been a need for a suitable primer in this field.

Joseph Lakowicz has attempted to remedy this need by bringing within a single monograph the basic introduction, essential theory and working practice of the most important aspects of fluorescence spectroscopy, at least as encountered in the life sciences. The reader has the vicarious benefit both of what is clearly a thorough knowledge of the literature, and of the author's experience in a well-known laboratory since his treatment strongly reflects the influence of Gregorio Weber to whom the book is dedicated. This is no small recommendation in itself. Phase-modulation techniques, after two decades of undeserved and incidental eclipse by pulse-excitation, are rightly restored to pre-eminence, while the phase-dependent method developed by the author for resolution of heterogeneous emission occupies a complete short chapter. Longer, well-illustrated sections are devoted to the fundamental fluorescence parameters and to a selection of excited-state processes implied by the "spectroscopy" in the title. As the latter suggests, the main emphasis is on fundamental aspects, while examples are taken almost entirely from protein and membrane systems.

A description of the essential instrumentation, calibration methods, common malfunctions and experimental pitfalls comes immediately after a short general introduction. This introduction, however, is barely adequate in conveying the range of molecular information potentially made accessible by appropriate strategies, and an early chance to whet appetites is rather missed. That said, the level of presentation is nicely poised between the superficial and the recondite. So that the reader has some likelihood of pursuing them, references are restricted to major benchmark publications (except for several "unpublished observations", which would have been better dealt with in the text). A useful feature, stressing the didactic intention of the author, is the inclusion of simple problems at the end of most chapters; if attempted, these oblige the reader to understand fully the main thrust of the preceding material. Correct solutions are also provided for reassurance.

Lakowicz's aim in writing this book was to satisfy the requirements of those interested in understanding the principles underlying the various fluorescence techniques encountered in contemporary research. To my mind, he has succeeded. □

F.W.J. Teale is the Reader in Physical Biochemistry in the Department of Biochemistry, University of Birmingham.

NEW FROM NORTH OXFORD ACADEMIC

Two key books on Japan

Japan: Science & Technology Outlook

Based on the White Paper recently prepared by the Japanese Science & Technology Agency, this book deals extensively with Japan's current progress in the development of new and original technology in such areas as nuclear fusion, space technology, bio-engineering, electronics and communications, marine technology and new materials. Authoritative data is presented on all aspects of Japanese research and development, including details of international co-operation.

ISBN 4 938329 11 5 £44.00 net

The latest edition of the
Computer White Paper

Provides each year a comprehensive picture of Japan's DP industry. Many graphs and tables are included to give a clear and authoritative picture of the industry and its policies.

NEW FROM BUTTERWORTHS

Gaseous Air Pollutants and Plant Metabolism

Edited by

M J Kozioł,
DPhil, Botany School, University of Oxford

F R Whatley,
PhD, Sherardian Professor of Botany, University of Oxford

The biochemical interactions of gaseous air pollutants with plant metabolism is a subject of increasing interest and study. This volume contains contributions from leading experts dealing with the effects of the major gaseous pollutants on aspects of plant metabolism including bioenergetic pathways, enzyme activities, metabolite pools and cell buffering capacities.

Gaseous Air Pollutants and Plant Metabolism is an essential review for research workers in botany, biochemistry, agriculture and the environmental sciences and for industrial and governmental organizations concerned with air pollution damage and air quality.

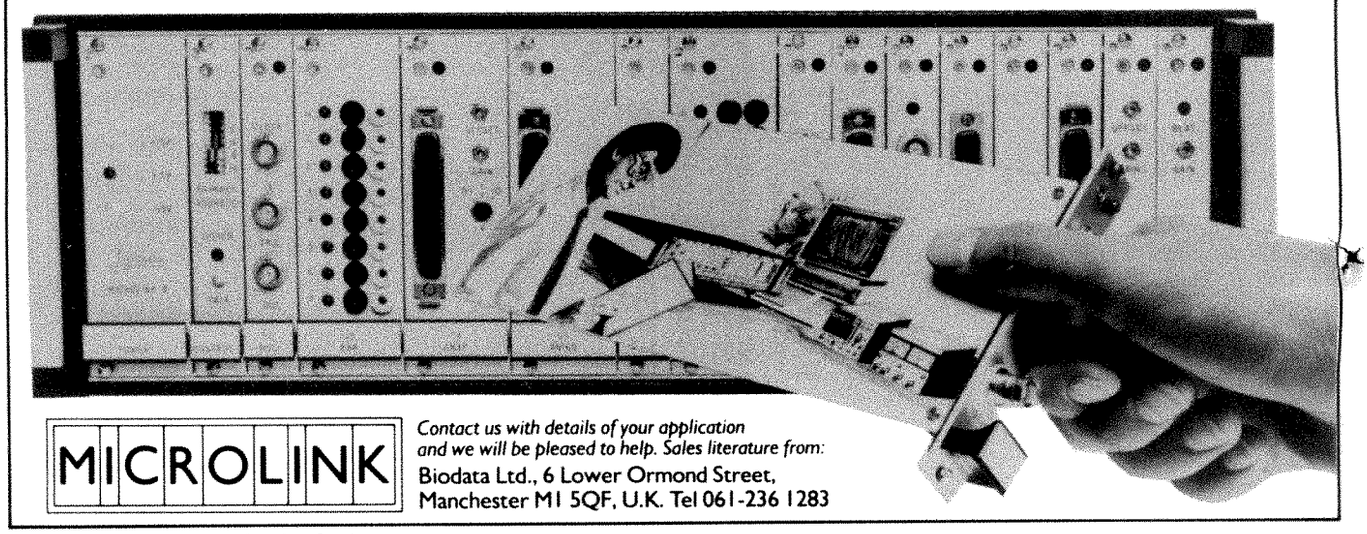
MICROLINK - THE MOST FLEXIBLE COMPUTER INTERFACE



Full modularity MICROLINK is a fully modular laboratory interface designed and constructed to the highest professional standards. MICROLINK uses the IEEE-488 bus, the only real choice for instrumentation systems.

Superlative specification An unsurpassed range of 30 modules including analogue and digital inputs/outputs, timers, counters, RS-232 and thermocouple inputs, allows you to connect almost any instrument to your computer. Data transfer rates of upto 50 Kbytes per sec. are achievable and upto 256 analogue inputs can be accepted.

Full software support Programming manuals are available for most computers with IEEE-488 facilities. Sample programs are provided in BASIC so that you can get your measurement/ control system running with minimum delay.

Universal application MICROLINK has been used in environments as varied as North Sea oil production platforms and hospital neurological units, in applications such as: data logging, experimental monitoring and control, environmental monitoring, automatic test and high speed data acquisition.

Appointments

Professor R.L. Wain has been appointed the first Royal Society Kan Tong-Po visiting professor to Hong Kong. The visiting professor scheme has been set up to allow scientists from the Commonwealth and the United States to spend four to ten months in the universities of Hong Kong, assisting with research and lecturing whilst pursuing their own research interests.

Awards

Applications are invited from young Australians and permanent residents in Australia for the Fogarty International Centre's research fellowships. The awards are designed to allow research in health-related fields in any biological or medical laboratory in the United States. Up to six awards may be made from Australia, and each fellowship lasts for twelve months, although an extension of a year may be considered. Candidates must have achieved a doctoral degree in the health sciences, preferably within the last six years and not more than 10 years ago. A stipend of $18,000 to $22,000 is provided according to relevant postdoctoral experience. Further information and application forms are available from the Australian Academy of Science, PO Box 783, Canberra, ACT 2601, Australia.

The British Medical Research Council is looking for candidates to nominate for the NIH international research fellowships of 1985–86. A competition for nomination for these awards will be held by the MRC in June 1984. The research fellowships are awarded for 12 months at a stipend level that ranges from $16,000 to $20,000 per year depending on experience. Application forms are available from The Training Awards Group, Medical Research Council, 20 Park Crescent, London W1N 4AL, UK.

The British Institution of Production Engineers has made the following awards: the International Award to **Dr Alan Puckett** of Hughes Aircraft Company; the Mensforth Gold Medal to **Mr Peter Jefferson** of British Aerospace; the Nuffield Award to **Sir Robert Telford** of Marconi Electronics and the Institution Silver Medal to **Mr John Adler**, former chairman of the Institution's northern region.

Foulkes Foundation fellowships have been awarded to **Miss Susan Griffith** of University College, London; **Dr Mary Ninkovic** of the University College Hospital Medical School, London; **Dr Deenan Pillay** of the University of Newcastle-upon-Tyne Medical School; **Dr Richard Sheaves** of Oxford University; **Dr Kevin Tyler** of Birmingham University and **Mr David Manuel** of Cambridge University.

Meetings

1–3 March, **Symposium on the Clinical Management of the Elderly Patient,** Florida (The Health and Education Council, Franklin Square Hospital, Essex Community College, Baltimore County Health Department, 7201 Rossville Boulevard, Baltimore, Maryland 21237, USA).

6–9 March, **Oceanology International Exhibition and Conference,** Brighton, UK (Oceanology International Conference and Exhibition, Spearhead Exhibitions Ltd, Rowe House, 55–59 Fife Road, Kingston upon Thames, Surrey KT1 1TA, UK).

18–20 March, **Course on Biotechnology in Oil Production,** University of London (Professor V. Moses, School of Biological Sciences, Queen Mary College, Mile End Road, London E1 4NS, UK).

19–21 March, **Workshop on Freezing and Quality Control,** Rockville, USA (Mr David Grounds, Workshop Coordinator, American Type Culture Collection, 12301 Parklawn Drive, Rockville, Maryland 20852, USA).

21 March, **Conference on the Synthetic Applications of Ynes, Enes and Ones,** London (Dr W.B. Turner, Process Development Department, ICI Pharmaceuticals Division, Hurdsfield Industrial Estate, Macclesfield, Cheshire SK10 2NA, UK).

26 March, **International Meeting on Sensory Interactions,** London (Dr H.J.H. MacFie, MRI, Bristol BS18 7DY, UK).

26–28 March, **Workshop on the Use of Computers in Radiology and Oncology,** Geneva (Professor R.J. Berry, Organizing Secretary, Department of Oncology, The Middlesex Hospital Medical School, London W1N 7PN, UK).

26–30 March, **Residential School on Metallo-Organic Chemical Vapour Deposition: Theory and Practice,** Queen Mary College, London (Ms L.A. Hart, Royal Society of Chemistry, 30 Russell Square, London WC1B 5DT, UK).

26–30 March, **International Symposium on the Application of Computers and Mathematics in the Mineral Industries — APCOM,** London (Conference Officer, The Institution of Mining and Metallurgy, 44 Portland Place, London W1N 4BR, UK).

26 March–15 June, **Course in Aflatoxin Analysis and Mycotoxins,** London (Training and Visitors Unit, Tropical Development and Research Institute, 127 Clerkenwell Road, London EC1R 5DB, UK).

27–30 March, **International Conference on Microbiological Quality Assurance in Industry,** Brighton, UK (Beverly Humphrey, Scientific Symposia Ltd, 33–35 Bowling Green Lane, London EC1R ODA, UK).

2–4 April, **Consensus Development Conference on Osteoporosis,** Bethesda, Maryland (Mr Peter Murphy, Prospect Associates, Suite 401, 2115 East Jefferson Street, Rockville, Maryland 20852, USA).

3–5 April, **Symposium on Solids/Liquids Separation Practice and the Influence of New Techniques,** Leeds, UK (Dr Paul Preece, Department of Chemical Engineering, University of Leeds, Leeds LS2 9JT, UK).

3–6 April, **International Conference on Energy Options,** London (The Institution of Electrical Engineers, Savoy Place, London WC2R OBL, UK).

9–11 April, **International Conference on Simulation for Nuclear Reactor Technology,** Cambridge, UK (The Conference Secretary, The Institution of Nuclear Engineers, 1 Penerley Road, London SE6 2LQ, UK).

9–13 April, **Residential School on Inorganic Polymers,** London (Ms L.A. Hart, Royal Society of Chemistry, 30 Russell Square, London WC1B 5DT, UK).

10–12 April, **International Conference on Flow Measurement in the Water Industry,** Glasgow, UK (Conference Section, National Engineering Laboratory, Glasgow G75 OQU, UK).

16–19 April, **Annual Chemical Congress of the Royal Society of Chemistry,** University of Exeter, UK (Dr John Gibson, The Royal Society of Chemistry, Burlington House, London W1V 0BN, UK).

17–19 April, **Annual Meeting of the European Society for Clinical Investigation,** Milan, Italy (Organizing Secretariat, Fondazione Giovanni Lorenzini, Via Montenapoleone, 23-20121 Milan, Italy).

29 April–3 May, **Annual Meeting of the American Oil Chemists' Society,** Dallas, Texas (Meetings Coordinator, American Oil Chemists' Society, 508S Sixth Street, Champaign, Illinois 61820, USA).

15–16 May, **International Symposium on Cost and Benefit of Radioimmunoassay,** Milan, Italy (Organizing Secretariat, Fondazione Giovanni Lorenzini, Via Montenapoleone, 23-20121 Milan, Italy).

The **Conference on Hazardous Waste Management** due to take place on 8 December 1983 will now be held on 3 April 1984 at the Sudbury Conference Centre, Newgate Street, London EC1, UK.

The **International Conference on Advances in Surface Coating Technology** which was scheduled to take place in June 1984 has been postponed until 13–15 June 1985.

Students and industrial sponsorship

Richard Pearson*

In certain specialized areas the role of industry in supporting British undergraduates is significant. It can have unexpected consequences.

STUDENT finance has been high on the debating agenda for a number of years. The value of the means-tested grant for British undergraduates is currently £1,660 per annum plus fees although few students receive the full amount because of the means test, with many parents not making their full contribution. Although the real value of the grant was fairly stable throughout the 1970s, it has fallen by about 10 per cent in the past couple of years (Fig. 1). Even so, the British undergraduate is considered better off than his contemporary in Japan, who has to take out a loan, while students in most of Europe and North America have to rely on a combination of loans (often at low rates of interest) and grants, supplemented in some cases by scholarships. In the United Kingdom, the current pressure to reduce public expenditure means that loan

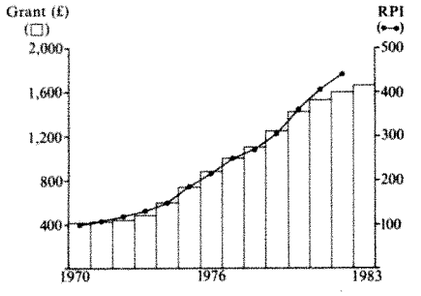

Fig.1 The "real" value of the student grant in Britain.

schemes could well be reconsidered in the next few years, although opponents argue that loans lead to only limited cost savings, while seriously affecting certain groups, such as women and those from poorer homes.

One source of finance rarely considered in this debate is industrial sponsorship. The full extent, in terms of money spent and numbers involved, is unknown. Most sponsorship is, however, concentrated in the area of engineering, with a smaller involvement in some of the pure sciences and in business and related studies. A recent report[1] from the Institute of Manpower Studies has shown that more than 2,200 (one in four) final-year engineering students were sponsored in 1983, which suggests the total number of sponsored students in higher education is probably over 10,000. Total expenditure by industry is likely to be several million pounds each year.

Sponsorship can take many forms. A student may be a salaried member of the staff of the sponsoring organization, he or she may receive a bursary worth up to £915 a year on top of the mandatory grant, or may have some mix of mandatory grant, bursary and salary when working in vacations or on periods of industrial work if on a sandwich course.

Employers sponsor students for a variety of reasons. For some it is a form of patronage, helping existing employees, often bright craftsmen and technicians, to advance their careers. For most, however, it is a means of guaranteeing a supply of well-trained recruits in the future, particularly in the "shortage" subjects of electronic and mechanical engineering. Sponsorship is also seen as providing an opportunity to make a detailed assessment of an individual's capabilities, as a means of influencing students' choice of subject and institution of study, as a way of attracting high quality school leavers, and to improve collaboration between industry and higher education. There is of course a financial cost involved, up to £4,000 per student over the duration of the course, and there is often the need to provide training and work experience.

In the past, some employers have sought legally to bind the student to the company for a period of years after graduation but this now happens only in the armed forces where the undegraduate becomes an employee. In recent years, 50–80 per cent of sponsored graduates have joined their sponsoring organizations, with each side rejecting the other in roughly similar proportions; some employers are, however, able to retain all those they want. Most students are sponsored from the start of their course, with the majority recruited directly from school, often only from local areas. More than half the employers limit their sponsorship students to particular universities, and in a few cases to particular polytechnics.

Among the 2,200 final-year engineering graduates sponsored in 1983, most were to be found in mechanical (38 per cent) and electrical/electronic (35 per cent) engineering, and relatively few in civil or chemical engineering. While two-thirds were in universities, the proportions of sponsored students, when compared on a subject basis, were similar in the universities and the polytechnics. Overall, 35 per cent of mechanical and 28 per cent of electrical/electronic engineers were sponsored (Fig. 2). It is interesting that it was the largest university/polytechnic departments (with over 50 final year students) that had the highest level of sponsorship and the middle-sized departments (25–49 final year students) that had the lowest.

In the past five years, more than 250 employers have been involved in sponsorship, some with only an occasional student, others with a regular intake of 50 to 100 a year. The number of companies sponsoring students has fallen as training budgets and recruitment levels have been cut back because of the recession. Nevertheless, the number of places on offer has grown slightly, with the number of places for electronic engineers increasing dramatically in response to expected shortages in future years.

Looking to the future, most employers expect to continue with their current sponsorship policies, while one in five expect to increase and one in seven to decrease their level of sponsorship. In the case of electronics, sponsorship has been rising rapidly. As a result, perhaps half of the graduates expecting to enter the labour

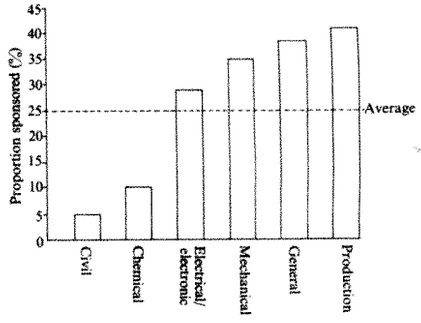

Fig.2 Proportion of final-year engineering students at UK universities and polytechnics sponsored by an employer during 1983.

market in the next few years will already be notionally committed to a particular employer. While not all will join that employer, it seems that the "free" market of electronics engineering graduates seeking employment will be even smaller than the already inadequate supply than has been forecast. This will compound the future recruitment difficulties of all types of employers, although the sustained high level of sponsorship may have an influence on subject and career choice by would-be students.

*Institute of Manpower Studies, University of Sussex, Falmer, Brighton BN1 9RF, UK.

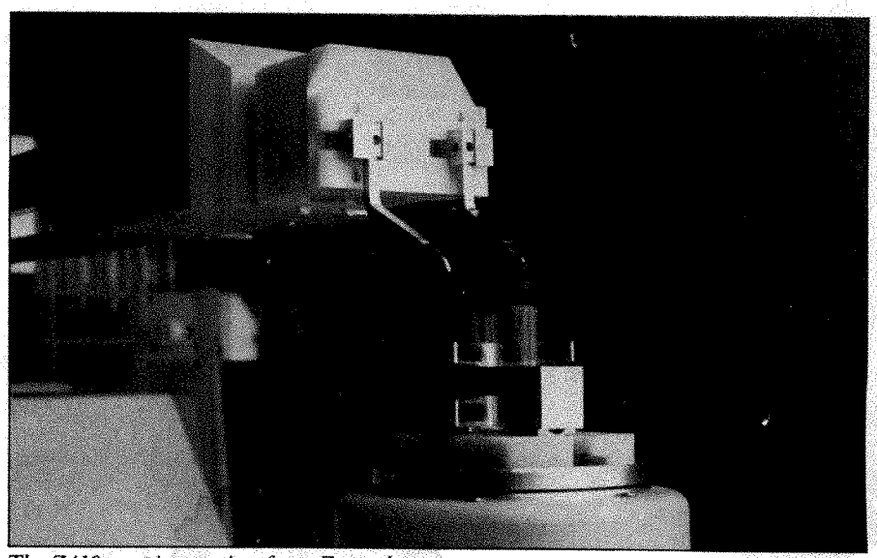
1. Gordon, A., Hutt, R. & Pearson, R. *Undergraduate Sponsorship: Implications for the Labour Market*, Interim Report (IMS, 1983).

The items featured in this week's selection include such diverse instruments as a colloid osmometer, an infrared filter and a powder sampler

● A new line of rotary mechanical homogenizers is available from Heat Systems-Ultrasonics. The Astramixer units mix, emulsify, disperse and homogenize by high intensity or mechanical and hydraulic shearing action. Two laboratory-sized units are included in the line. The first, the micromixer, has three different rotor/stator sets; 7 mm, 12 mm and 21 mm. This allows samples of 250 μl to 1 litre in size to be processed. The standard laboratory unit is available with 35 mm and 45 mm rotor/stator sets for processing 100 ml to 20 litre batches.
Circle No. 100 on Reader Service Card.

● A new range of solid-state mini-ion selective electrodes is available from World Precision Instruments. Each electrode is 10 cm long and has a tip diameter of 3 mm. Calcium, sodium, potassium and chloride sensors can now be supplied.
Circle No. 101 on Reader Service Card.

● Wescor has released a low-cost version of its colloid osmometer. The instrument handles samples of 30 μl and can deal with whole blood flow-through sampling. It has a short response time, new wet-packed premounted membranes and a longer membrane shelf-life.
Circle No. 102 on Reader Service Card.



● Infrared filters designed by Infrared Engineering for inclusion in optical communications equipment are now being held as stock items. Filters ranging in size from 3 to 25 mm in diameter are available for use at wavelengths of 850, 904, 1,060 and 1,300 nm. Infrared filters of other sizes for use at other wavelengths can also be supplied to individual specifications. The filters are optimized for use with light emitting diodes (LED) which typically operate within the 800–1,400 nm waveband or with lasers used as coherent light sources operating at 1,060 nm.
Circle No. 103 on Reader Service Card.

● The new computerized model of Columbus Instruments' animal oxygen consumption monitor can simultaneously measure eight animals located in eight separate cages. The stability of the oxygen sensors is around 0.0054% oxygen which allows for 1% accuracy in measuring oxygen consumption. Results of measurements are printed at 10-min intervals in microlitres of oxygen per kilogram of body weight per hour. The system can operate for 24 h without interruptions. The oxygen consumption monitor can be used for any size of animals by changing the size of the animals' cages. A facility to measure CO_2 production can be added to the system.
Circle No. 105 on Reader Service Card.

● A new automated system for measuring red blood cell aggregation has been introduced by Myrenne Instruments. The Myrenne model MA-1 is based on the Schmid-Schönbein principle and uses a rotating cone and plate arrangement with an integrated infrared photometer. A 20-μl blood sample is subjected to a shear rate of 600 s^{-1} between a rotating transparent disposable cone and a transparent stationary plate, resulting in a dispersion of red cell aggregates. After 10 s, the cone is stopped and the optical effects of recurring aggregation are registered as an increase in optical transmission. The measured parameter, the 'mean extent of aggregation' (MEA), is the integrated area below the transmission curve during the first 10 s after the cone stopped. The MEA is computed and displayed on an LED readout. An analog signal output is provided for use with a recorder.
Circle No. 106 on Reader Service Card.

● Regency Electronics is now marketing a 30-channel programmable scanner that can monitor 15,760 frequencies (in six VHF and UHF bands). The Regency Z30 comes preprogrammed for 30 frequencies in its six covered bands: low VHF (30–50 MHz), VHF 2m amateur (144–148 MHz), high VHF (148–174 MGz), UHF 0.75m amateur (440–450 MHz), standard UHF (450–470 MHz) and extended UHF (470–512 MHz). Its telescoping antenna is electronically optimized for each band and an antenna jack can be provided for an external antenna. When searching, the Z30 covers 400 VHF frequencies (2 MHz) in about 34 s and 400 UHF frequencies (5 MHz) in about 30 s. When searching its 30 programmed channels it covers about 15 channels per second. A channel lockout feature can exclude any selected channels from being scanned. A selected priority channel is sampled every 2 s. If active, it automatically overrides any other signal.
Circle No. 107 on Reader Service Card.

● The Z410 capping station from Zymark automates the capping and uncapping of the screw cap containers used in the laboratory. It is a Zymate laboratory automation system. Sample containers can be automatically uncapped and the solution removed or reagents added. Containers can then be recapped. Vials holding samples which have been prepared for gas chromatography or HPLC can be automatically filled and capped using the Zymate system and capping station. The capping station can be added to any Zymate system and contains all the necessary software.
Circle No. 108 on Reader Service Card.

The Z410 capping station from Zymark

OXFORDSHIRE HEALTH AUTHORITY
Churchill Hospital
MEDICAL GENETICS DEPARTMENT

A CYTOGENETICIST

is required from 1st April 1984 for two years to assist in a clinical research project on karyotyping of chorionic villi. Applicants should possess a first or upper Second Class honours degree, and have experience in human cytogenetics. Salary on Whitley Scale, commensurate with qualifications and experience scale starting at £6,520.

Enquiries to Dr Jon Jonasson, Department of Medical Genetics, Churchill Hospital, Headington, Oxford. Tel Oxford 0865/62834 or 0865/64841 ext 7059.

Job description and application form from Personnel Officer, Churchill Hospital, Headington, Oxford. (1136)A

CHAIRMAN

DEPARTMENT OF ANATOMY

Applications are invited for the position of Professor and Chairman, Department of Anatomy, Schools of Medicine and Dentistry, University of Alabama in Birmingham. We are seeking candidates with research and teaching experience, leadership qualities, and administrative skills. This department has teaching responsibilities for graduate students in anatomy, medical, dental and other students.

Please submit applications and a curriculum vitae to: Antonietta D Hyche, Administrative Officer, University of Alabama School of Medicine, Dean's Office — MEB 306, Birmingham, Alabama 35294. An Equal Opportunity/Affirmative Action Employer. (NW263)A

UNIVERSITY OF TORONTO

PHARMACOLOGIST

Assistant or Associate Professor (Tenure Stream Position). Ph.D. with several years of post-doctoral experience in pharmacology. Demonstrated excellence in teaching and research in pharmacology. Other factors being equal, Cardiovascular Pharmacologist preferred. Salary commensurate with qualifications and experience. Effective date of appointment: July 1, 1984.

Apply to: Chairman, Department of Pharmacology, Medical Sciences Building, University of Toronto, Toronto, Ontario M5S 1A8. Closing date for receipt of applications: April 30, 1984.

In accordance with Canadian Immigration requirements, this advertisement is directed to Canadian citizens and permanent residents. (NW252)A

MONASH UNIVERSITY
Melbourne, Australia
DEPARTMENT OF BIOCHEMISTRY

SENIOR TUTOR

Postdoctoral graduates or those about to complete degree for position involving limited teaching to medical or science students and participation in ongoing research on connective tissue metabolism. Expertise in enzymology, particularly would be relevant to our research into regulation of turnover of connective tissue macromolecules in normal and arthritic tissue. Enquiries to Professor D A Lowther. Salary $A20,164 — $A23,100 pa.

Applications including Ref No. 30213A, curriculum vitae and referees to the Registrar, Monash University, Clayton, Vic 3168, Australia, with a copy to the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, by 29/2/84. (W725)A

Head of Pharmacology

Continental Europe

This is a senior appointment within the modern and well-equipped Research Centre of a European pharmaceutical company which has a growing international reputation.

Research is centred on the company's 250-strong laboratories pleasantly located in a French speaking part of Europe, and there are strong cooperative ventures with other laboratories throughout Europe – including the UK, as well as the USA, Canada and Japan.

The company now seeks an internationally-oriented Departmental Head for its Pharmacology Group, to lead a team of 30 by coordinating the activities of the specialist section heads and, ideally, to provide a major input in cardiovascular research. An important rôle of the Head of Pharmacology will be to enhance the links with

UK equivalent: £20,000+

Medicinal Chemistry and Biochemistry, as well as the more developmentally-oriented departments.

We therefore seek an able PhD scientist who has expertise at team leader level within the pharmaceutical industry, and a broad appreciation of the major branches of pharmacology. Existing European experience would be valuable, but a clear willingness to see your career develop within continental Europe is more important.

The starting salary will be negotiable according to pharmacological and managerial experience, but is likely to provide a standard of living equivalent to at least £20,000 in the UK.

Please write in confidence for an application form, or phone if you would like to discuss the appointment further before applying:

RESEARCH HEAD

Drug Delivery Systems Research

The Upjohn Company, a worldwide leader in pharmaceutical research, is seeking applicants for the position of Research Head of the newly formed Drug Delivery Systems Research unit within the Pharmaceutical Research and Development division.

The successful candidate will lead an expanding interdisciplinary team of professionals dedicated to the elucidation of innovative drug delivery systems. The Unit will interact with other scientists responsible for development of specific human and veterinary products. Responsibilities will include the development of strategies for the discovery of future drug delivery systems, and the management of associated research activities. The successful candidate will be responsible for developing an effective program in drug delivery basic research and will assume responsibility for the evaluation, implementation, and development of collaborative research programs with academic institutions and other appropriate sources.

In addition to a Ph.D. in the biological, chemical, or pharmaceutical sciences, applicants must possess an outstanding publication record and have a minimum of three years' research management experience. Good leadership and communication skills, and the ability to relate to people at various levels, are essential.

Upjohn offers a stimulating research environment, opportunity for career growth, competitive salary and benefits, and relocation assistance.

Kalamazoo is a medium-sized Southwestern Michigan community with immediate access to a mix of excellent cultural, educational, and recreational pursuits, including numerous lakes and a four-season climate.

For confidential consideration, please send your resume to: **Lance D. Williams - 15819-J, Employment, THE UPJOHN COMPANY, 7000 Portage Rd., Kalamazoo, MI 49001, USA.**

Senior Medicinal Chemist

RESEARCH CENTRE

COTE D'AZUR

We are a well known research laboratory and we are creating a position for a Senior Medicinal Chemist in our **BIOCHEMISTRY Department.** He will take part in the creation and initiation of basic and applied research projets. Working closely with pharmacologists and biologists, he will lead a team of technicians. This position will suit a man or woman with a Ph. D. (or équivalent) in Chemistry with 3 to 6 years of research experience in the pharmaceutical industry. Good knowledge of modern methods in organic synthesis, experience of analytical techniques and familiarity with the study of structure-activity relationships are desirable. With excellent working conditions, this laboratory is at the forefront of research in its field and has excellent equipment housed in modern laboratories. This post will attract ambitious researchers of international standing who are bilingual in English and French. Please send a hand-written letter and C.V. to Mme FOURNIAT, under reference 23673/NA at Sélé-CEGOS Méditerranée, 35, rue Pastorelli, 06000 NICE (FRANCE).

HINDUSTAN CIBA-GEIGY LIMITED

requires a

PHARMACOLOGIST

for its Reseach Centre in Goregaon, Bombay, India

Applications are invited from candidates of Indian nationality, aged about 35 years, and holding an MD or PhD in pharmacology, who are capable of independently planning and conducting basic and applied pharmacological research into the central nervous system, with special emphasis on electrophysiological aspects, and the cardiovascular system. The successful candidate will be expected to furnished comprehensive preclinical data on the pharmacological activity profiles of potential new drugs.

At least five years' previous experience in research is essential, and preference will be given to applicants who have received their post-doctoral training in the U.S. or in Europe.

Applications, accompanied with curriculum vitae and a full list of publications, should be sent in strict confidence to: The Personnel Department, HINDUSTAN CIBA-GEIGY LIMITED, 14, J. Tata Road, Bombay 400 020, India.

(W716)A

HINDUSTAN CIBA–GEIGY LIMITED

Specialist in biotechnology at the Science Reference Library

Applications are invited from graduates and postgraduates with a background in microbiology, biochemistry or another discipline related to biotechnology to work on the European Biotechnology Information Project (EBIP). EBIP will be based at the British Library Science Reference Library in London and will be supported by funds from the European Commission. It will be run in collaboration with other European organisations.

The successful candidate will be primarily concerned with the provision of information services in biotechnology by the exploitation of the literature and other sources and the use of computer based techniques. A degree in biochemistry, microbiology or another appropriate subject is essential with an up-to-date knowledge of the field and a keen interest in genetic engineering and other new developments.

Desirable attributes are experience of laboratory work in industry or research, a qualification in librarianship or information science, a knowledge of information provision in biotechnology, experience of using microcomputers and automated methods of information searching, and good communication skills.

The capacity to speak French or German would be a particular asset.

The duration of the post will be one year with the possibility of renewal.

Salary £7,759 pa. plus £1,250 Inner London Allowance.

Application forms (returnable by 15 February 1984) are obtainable from Marie Loftus, The British Library Personnel Section, Sheraton House, 2 Sheraton Street, London W1V 4BH.

Tel: 01-636 1544 Ext. 514. (1147)A

The British Library BL

JAMES COOK UNIVERSITY OF NORTH QUEENSLAND

Professor of Physics

Applications are invited for the position of Professor of Physics. The appointee will also be Head of the Department of Physics. The position is available following the retirement of the Foundation Professor of Physics, Professor J.F. Ward.

The University wishes to develop its interests in physical oceanography and/or metoerology. Accordingly it seeks to appoint a person with appropriate higher degree qualifications and a proven record of research and publication in either or both of these fields.

The salary for the position of Professor is currently $A48,997 per annum, and in addition a locality allowance will be payable at the rate of $A496 per annum for a staff member with dependants (as defined) or $A248 per annum for a staff member without dependents.

Further information may be obtained from the Registrar, James Cook University, Townsville, Qld 4811, Australia, with whom applications close on March 1, 1984. In reply please quote Reference No. 83106. (W705)A

UNIVERSITY OF CAMBRIDGE

SUB-DEPARTMENT OF VETERINARY ANATOMY

POST-DOCTORAL

position available immediately to study effects of exercise on dietary metabolism and egg production in birds. The project is expected to be funded by the Agricultural and Food Research Council, for 3 years. Salary to be within the Cambridge Research Assistant scale £7,190 to £9,425 depending on age.

Send CV and names of 2 referees to: Dr J Brackenbury, Sub-Department of Veterinary Anatomy, Tennis Court Road, Cambridge CB2 1QS. (1106)A

SABBATICAL LEAVE IN SPANISH LABORATORIES

In order to promote the interaction between the Spanish Scientific Community and scientists working outside Spain, the CAICYT (Spanish National Council for Research & Development) is launching a Program encouraging scientists to spend their Sabbatical leave in Spanish Laboratories. The maximum length of stay is one year and the Program will be in operation from 1st September 1984 to 31st July 1986. The visiting scientists will receive a salary that will be awarded on the basis of qualifications and of the percentage of their current salary that is maintained by their home institution. Also some funds for expendable material in the receiving institution will be provided.

Scientists willing to take part in this Program are requested to contact the Spanish Laboratory in which they intend to stay. The CAICYT will also help, on request, to establish a connection between Scientists eventually interested in the Program and those Spanish laboratories working in their area of interest. These contacts should result in a joint proposal that must be submitted to CAICYT before 1st June 1984. Full details of the data that will be required are available either from the Spanish institutions or from CAICYT. The selected candidates will be notified not later than 1st July 1984.

All information concerning this advertisement should be requested from Dr Marisa Pacios, CAICYT, Edificio Torre Rioja, calle Rosario Pino, 14-16, Madrid 20, Spain. Tel. (34)-1-4501063.

FRESHWATER BIOLOGICAL ASSOCIATION

VACANCY FOR PHYSICAL LIMNOLOGIST AT WINDERMERE

Applications are invited for a three year post in physical limnology, to work on exchanges of energy and matter across water-atmosphere and water-sediment interfaces and transport of dissolved and particulate matter in lake ecosystems. Potential candidates should possess at least a good honours degree in physics and/or mathematics and should ideally have some experience of environmental data collection and processing.

Salary and conditions of service are analogous to those of Scientific Officer (£5,682 — £7,765) or Higher Scientific Officer (£7,149 — £9,561) in the Civil Service, gross pay depending on qualifications and experience.

Full details and application forms from the Secretary, Freshwater Biological Association, The Ferry House, Ambleside, Cumbria LA22 0LP (tel: 09662 2468). Closing date 14th February 1984. (1084)A

UNIVERSITY OF WARWICK

POSTDOCTORAL RESEARCH ASSOCIATES

Two positions are available in the Department of Biological Sciences on SERC funded projects:

(i) to work on an in vivo and in vitro study of microbial oxygenase-based bioconversion systems. This research is funded by a three year grant from the Biotechnology Directorate with a view to understanding the fundamental mechanisms which will enable those microbial systems to be used in the production of value added oxygenated chemicals. A working knowledge of enzyme regulation, microbial physiology/biochemistry or oxygenase enzymes would be an advantage. The successful candidate would be expected to collaborate with a co-worker already appointed on this project.

The post is available for three years (commencing as early as possible) on a starting salary up to £8,530 pa on the Research IA scale: £7,190 — £11,615 pa.

(ii) to work on the mechanism of action of the methane monooxygenase enzyme complex from bacteria. The work will cover the purification of the proteins by techniques already developed in the group, and analysis of the iron sulphur flavoproteins on the functioning complex by visible and e.s.r., spectroscopy and stopped flow techniques.

The post is available for 2½ years (commencing as early as possible) on a starting salary up to £8,080 pa on the Research IA scale: £7,190 — £11,615 pa.

Applicants should send a cv with the names and addresses of two referees to the Executive Officer, Department of Biological Sciences, University of Warwick, Coventry CV4 7AL by mid February. Informal enquiries and further particulars from Professor H Dalton, 0203/24011, ext 6025. (1103)A

Biotechnology Australia

Career Opportunities in Biotechnology

Biotechnology Australia Pty Ltd, Australia's leading biotechnology research company, is in the process of expanding its research and development activities. There are immediate opportunities for the research and development positions listed below.

The company provides a first class research environment for over 70 staff in modern laboratories on Sydney's North Shore. The laboratories are equipped with a full range of instruments and fermenters necessary for projects requiring the skills of molecular biologists, microbiologists and biological chemists. Topics under investigation include studies of new methods for vaccine production with recombinant DNA techniques, biological control of insect pests with genetically modified bacteria and parasitic nematodes, and the microbiological leaching of minerals. Most projects involve collaboration with leading groups in universities, CSIRO and research institutions.

The research group is supported by experts in planning and evaluation and there are extensive facilities for scale-up and process development.

Applications are now invited for the following seven positions.

Molecular Biologists

Position No. 1001 is for a candidate with Post-Doctoral experience in molecular biology or allied fields of biochemistry or microbiology, for appointment as a Research Scientist.

Position No. 1002 is for a candidate with an Honours Degree in similar subjects or in immunology, for appointment as an Experimental Officer.

Position No. 1003 is for a Post-Doctoral Fellow funded for 3 years in the first instance. Training in recombinant DNA and allied immunological techniques is required.

Position No. 1004 is for a Post-Doctoral Fellow funded for 2 years in the first instance for the development of vaccines against enteric infections using recombinant DNA technology.

Fermentation Scientist

Position No. 1005 is for a candidate with an Honours Degree in microbiology or fermentation with knowledge of chemical or biochemical engineering. Appointment will be at the Experimental Officer level to work on solid and liquid fermentations and product recovery.

Entomologist

Position No. 1006 is for a candidate with an Honours or higher degree in entomology for appointment as an Experimental Officer. The position would be for 2 years in the first instance.

Biotechnologist

Position No. 1007 is for a candidate with an Honours Degree in microbiology, biochemical engineering or allied discipline for appointment as an Experimental Officer. The position would be for 2 years in the first instance.

All positions carry salaries and conditions of employment competitive with other leading research organizations.

Applications including a c.v. and names of two referees should be sent to:

Professor N. S. Willetts
Director of Research
Biotechnology Australia Pty. Ltd.
P.O. Box 20
Roseville N.S.W. 2069 Australia

(W712)A

BIOCHEMICAL/CHEMICAL/TECHNICAL ASSISTANT

A post is available for an assistant to work on a programme concerning the biochemistry of the nervous system. Training and/or experience in biochemical and chemical techniques is essential. Salary according to BAT.

The post is limited to the end of 1984 with possibility of extension.

Application to: Max-Planck-Institut für biophysikalische Chemie, Abteilung Neurochemie, Sekretariat, Postfach 2841, D-3400 Göttingen, FR Germany. (W714)A

COMMONWEALTH AGRICULTURAL BUREAUX

Applications are invited for the post of

PLANT PATHOLOGIST

in the

COMMONWEALTH INSTITUTE OF BIOLOGICAL CONTROL

The Commonwealth Institute of Biological Control is one of the four Institutes and ten Bureaux which together comprise the Commonwealth Agricultual Bureaux, and provide a comprehensive world-wide information service in agriculture and related fields.

The C.I.B.C. undertakes research and carries out projects on a contract basis from its bases in India, Trinidad, Kenya, Pakistan, Switzerland and the U.K. It also provides an information and advisory service in all aspects of Biological Control and on the development of integrated pest management programmes.

With the increasing interest in biological control worldwide, the C.I.B.C. is expanding and diversifying its programme. A Plant Pathologist is required to join the team in the U.K. Initially he will undertake screening of rusts in the U.K. as potential control agents for weeds in other countries. At the same time, he will be expected to examine the prospects for using rusts and other plant pathogens more widely for weed control, prepare research proposals and undertake field surveys overseas in connection with C.I.B.C. projects on weeds. It would be an advantage if he had an interest in fungal parasites of insects and was able to assist and advise entomologists on their collection, isolation and screening as insect control agents.

QUALIFICATIONS Candidates should have a PhD or equivalent research qualification in plant pathology with a proven interest in, or involvement in, the use of plant pathogens as biological control agents. Overseas research experience and an interest in fungal pathogens of insects would be advantageous.

SALARY & CONDITIONS OF SERVICE The successful candidate would be based at the Commonwealth Mycological Institute initially but some field and laboratory work would be carried out at C.I.B.C., Silwood Park. At a later date, the appointee might be expected to work full-time based at Silwood Park and would be expected to travel widely and to spend periods overseas, if required.

The salary would be in the ranges of £7,149 – £9,561 or £8,970 – £11,476 depending on qualifications and experience, with London Weighting £700 while based at C.M.I.

The appointment would be made on a 3 year contract in the first place with the expectation of permanent superannuated service if performance was satisfactory.

STARTING DATE The successful candidate would be expected to take up the appointment on, or as soon as possible after, 2nd April 1984.

Further information is available from: The Assistant Director, Commonwealth Institute of Biological Control, Imperial College, Silwood Park, Ascot, Berks SL5 7PY, U.K. Tel. No. (0990) 23911 Telex: 847964 Cables Comag, Slough to whom applications, including a CV and names and addresses of two referees, should be submitted by 29th February, 1984.

(1113)A

Applications are invited for faculty appointments in

PHYSICS

to be made in the Physics Department, Memorial University of Newfoundland, effective September 1, 1984. Both tenure-track and two-year contractual positions are being considered. Research opportunities are available in a number of areas, but primary responsibility for at least two years will be for instruction at the first-year level with related activities (e.g., student interviewing and advising, school visitations, etc.). Initial appointments will normally be at the assistant professor level and subject to final budgetary approval. Applications, including curriculum vitae and the names of three referees should be forwarded to:

Dr D.H. Rendell, Head
Department of Physics
Memorial University of Newfoundland
St. John's, Nfld. A1B 3X7

In accordance with Canadian Immigration policy, this advertisement is directed, in the first instance, to Canadian citizens and permanent residents of Canada. (NW248)A

DEAKIN UNIVERSITY
Geelong, Australia

SENIOR LECTURER OCCUPATIONAL HYGIENE

Applications are invited for appointment to the above post. The appointee will be responsible for the operation and future development of the occupational hygiene program.

Applicants must be occupational hygienists and graduates, preferably in one of the physical sciences or engineering, although applicants with backgrounds in medicine, toxicology etc will also be considered.

The appointee must hold a recognised professional qualification in occupational hygiene (eg: qualifications leading to professional membership of an appropriate occupational hygiene society) and have at least eight years relevant experience. A higher degree is desirable.

Salary: $A31390 to $A36585 pa.

The position will be for an initial term of four years, during which there will be a review for continuing tenure.

Applications (quoting reference number 84/01) should include a full curriculum vitae and the names and addresses of three referees and should be sent to the Personnel Branch, Deakin University, Victoria, Australia 3217, by 30 March 1984. Applicants resident in North America and Europe should send an additional copy of their applications to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom further information is available. (W707)A

THE UNIVERSITY OF WESTERN ONTARIO

BACTERIOLOGIST

Applications are invited for a tenure-track position, effective July 1, 1984, as Assistant Professor or Associate Professor, depending upon qualifications, in the Department of Microbiology and Immunology. Applicants should have a PhD and Post-Doctoral training in microbial biochemistry or biochemical aspects of microbial structure. Applicants must have demonstrated continuous ability to conduct and publish original, independent research.

The deadline for applications is March 15, 1984.

In accordance with Canadian Immigration requirements this advertisement is directed to Canadian citizens and permanent residents.

The University of Western Ontario is an equal opportunty employer.

Address correspondence to: Dr N R Sinclair, Chairman, Department of Microbiology and Immunology, University of Western Ontario, London, Ontario N6A 5C1.

(NW253)A

THE AUSTRALIAN NATIONAL UNIVERSITY

RESEARCH SCHOOL OF EARTH SCIENCES

Applications are invited fr suitably qualified men and wom for appointment to the followi positions:

POSTDOCTORAL FELLOW/RESEARCH FELLOW

A number of appointments will made during 1984. The fields which these appointments are ma will be guided by the Schoo evaluation of all applications, whi are invited in the following areas Earth Physics (seismilogy and tecto ophysics), Environmental Geoche istry, Geophysical Fluid Dynami Petrochemistry, Petrophysics (rc deformation), Trace Element G chemistry, Mineralogy, and C Genesis.

Closing date: 31 March 1984.

Conditions of appointment: Sal will be in accordance with qua cations and experience within ranges: Research Fellow $A23394 $30734 pa; Postdoctoral Fell Grade 1 (at fixed point) $A20164 $23100 pa. Current exchange rate $A1 = UK 62p.

Appointment, unless otherw stated, will be: Research Fell normally up to three years with possibility of extension to maxim of five years; Postdoctoral Fell normally two years, with possibility of extension to maxim of three years.

Grants are provided towards tra and removal. Assistance towa housing is given to an appointee fr outside Canberra. Eligil appointees will be required to join Superannuation Scheme Australian Universities. T University reserves the right no make an appointment or to make appointment by invitation at time.

Prospective applicants should w to the Registrar of the Univers GPO Box 4, Canberra, ACT 26 Australia, or to the Association Commonwealth Universit (Appts), 36 Gordon Square, Lon WC1H 0PF, for further particu before submitting applications.

THE WORLD HEALTH ORGANIZATION OF THE UNITED NATIONS

invites applications for the post of

MEDICAL OFFICER

Duties of the post include: Reviewing the situation in national health systems, so as to identify the most important problems and possible solutions for their reorientation towards health for all; Promoting the exchange of experience among Member States and ensuring appropriate technical support, if required; Initiating specific tasks, such as comparative studies and analysis of technical publications, in order to develop cumulative knowledge on health systems reorientation processes in various economic and socio-political conditions; Promoting liaison with and providing support to other programmes and activities, both within and outside WHO, related to organization of health systems based on primary health care; Contributing to scientific meetings, seminars and training courses in the field considered and acting as a resource person for Organization of Medical Care and as the Secretary to the relevant Expert Advisory Panel.

Interested candidates should have graduation in medicine with postgraduate training in disciplines related to the planning and management of health systems and at least ten years of practical experience in these fields at the national level and several years' experience in health systems and at least ten years of practical experience in these fields at the national level and several years' experience in health systems research and training. Experience in international work and problems of developing countries would be an advantage. Excellent knowledge of English or French with a good working knowledge of the other is required.

Salary commensurate with present earnings but not less than US$ 54,070 per annum plus an attractive international benefits package.

Applications are invited from candidates of either sex. Qualified candidates should send their detailed curriculum vitae quoting SHS/84 to:

Personnel (MPR)
World Health Organization
CH — 1211 Geneva 27

Closing date for receipt of applications: end March 1984.

Only those candidates under serious consideration will be contacted. (W709)A

TECHNICAL CHANGE CENTRE
PRINCIPAL RESEARCH FELLOWS

The Centre is seeking to appoint full-time Principal Research Fellows to work on research projects concerned with (a) the careers of graduate scientists and engineers, and (b) the contribution which British academic research makes to the advancement of UK engineering. Applicants should be graduates in science or engineering, or have other relevant qualifications, and have experience of interdisciplinary research studies.

The appointments will be for two years in the first instance. Salaries will be not less than £15,000 pa, depending on qualifications and experience.

Applications in writing, together with a full CV, should be sent to the Secretary, The Technical Change Centre, 114 Cromwell Road, London SW7 4ES from whom further particulars may be obtained. (1098)A

NATIONAL COUNCIL FOR SCIENTIFIC RESEARCH

Applications are invited from suitably qualified persons for the post of

INORGANIC/ANALYTICAL CHEMIST

Qualifications:
Post Doctoral experience in Chemical Engineering or Mineral Processing.

Salary:
Will be according to qualifications and experience on the following scales:
Senior Scientific Officer at K9444 × 372 — K10,932
Principal Scientific Officer at K10,176 × 600 — K12,576
Senior Principal Scientific Officer at K11,196 × 720 — K13,356
Chief Scientific Officer at K12,000 × 900 — K15,600

Applications giving full personal details, qualifications and experience, and names and addresses of three referees should be submitted to:
The Secretary General, National Council for Scientific Research, PO Box CH 158, CHELSTON, LUSAKA, ZAMBIA

(W717)A

Directorate of Fisheries Research, Lowestoft
Ministry of Agriculture, Fisheries and Food

Physical Oceanographer/ Dynamicist

...to work in the field of physical oceanography related to the disposal of low level radioactive wastes to the deep ocean.

You will be responsible for planning, field implementation and analysis of results of the MAFF contribution to the international SOFAR (neutrally buoyant) float experiments in the eastern North Atlantic ocean during 1984-86. Work also involves participation in projects examining the mixing processes occurring at the European Continental Slope, and in research cruises (up to 2 x 1 months duration per annum).

You should have a good honours degree or equivalent in physical sciences or mathematics and at least 2 years' relevant post-graduate experience with proven research ability in dynamical oceanography. A knowledge of ocean mixing processes would be advantageous.

Appointment as Higher Scientific Officer £7145-£9560 or Senior Scientific Officer (minimum 4 years' relevant post-graduate experience) £8970-£11475. Level of appointment and starting salary according to qualifications and experience.

RELOCATION ASSISTANCE MAY BE AVAILABLE.

For further details and an application form (to be returned by 24 February 1984) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours).

Scientific Civil Service

THE AUSTRALIAN NATIONAL UNIVERSITY
JOHN CURTIN SCHOOL OF MEDICAL RESEARCH

POSTDOCTORAL FELLOW/RESEARCH FELLOW/SENIOR RESEARCH FELLOW
(several positions)

Applicants for these research positions should have a PhD degree (or equivalent qualification) and expertise in any of the areas of research listed below. A number of appointments will be available from late 1984 or early 1985.

Department of Biochemistry: Head: Professor F. Gibson) Energy-transducing ATPase; membrane assembly; bacterial transport; bioenergetics; mechanism of action of classical and multifunctional enzymes; molecular biology; gene expression; differentiation; oncogenesis.

Department of Experimental Pathology: (Head: Professor P. C. Doherty) Biology and biochemistry of tumour metastasis, malignancy and host response; viral and auto-immune pathological process in the central nervous system; vascular and lymphatic pathology; inflammation; pathogenesis of malaria.

Department of Human Biology: (Head: Dr R. L. Kirk) Molecular biology of inherited disease, cytogenetics and somatic cell genetics; human population genetics, including DNA polymorphisms.

Department of Immunology: (Head: Professor B. Morris) Ontogeny of the immune response; immunology of the foetus and pregnancy; experimental surgery of the embryo and foetus; embryo transplantation; genetics of disease resistance; reproductive and developmental biology; tissue transplantation; physiology of the lymphatic system.

Department of Medicine and Clinical Science: (Head: Professor W. F. Doe) Mucosal immunity and inflammation; neutral proteases; interleukins and differentiation of bone marro wcells, macrophages and natural killer cells; pathogenesis of inflammatory bowel disease and colon cancer; neurophysiology of intestinal motility; calcium and cell regulation; makignant hyperpyrexia; asthma; platelets, atheroma and haemostasis; transplantation biology.

Department of Medicine and Clinical Science: (Head: Professor W. F. Doe) Mucosal immunity and inflammation; neutral proteases; interleukins and differentiation of bone marrow cells, macrophages and natural killer cells; pathogenesis of inflammatory bowel disease and colon cancer; neurophysiology of intestinal motility; calcium and cell regulation; malignant hyperpyrexia; asthma; platelets, atheroma and haemostasis; transplantation biology.

Department of Microbiology: (Head: Professor G. L. Ada) Histocompatability antigens; viruses; carcinogenesis; immunity to and epidemiology of viral infections.

Department of Pharmacology: (Head: Professor D. R. Curtis) Mammalian central transmitters; pain and analgesia; mammalian peripheral sympathetic synapses; biophysics of smooth muscle; nerve growth factors.

Department of Physical Biochemistry: (Head: Professor L. W. Nichol) Biological macromolecules; interacting protein systems; multienzyme complexes; enzymes of sulphur metabolism; protein conformation and hydration; secretory and blood proteins.

Department of Physiology: (Head: Professor (Elect) P. W. Gage from April 1984; Acting Head to 31 March 1984: Dr. R. I. Close)
Synaptic trasmission at peripheral and central synapses; calcium ionic and gating currents; charge movements in nerve and muscle; contractile activation in muscle; visual information processing.

Experimental Neurology Unit: (Director: Professor R. Porter) Neurophysiology; spinal cord; synaptic transmission at central synapses; respiratory neurophysiology; somatosensory pathways; control of movement; physiology of the cerebral cortex in primates.

CONDITIONS OF EMPLOYMENT: Salary will be in accordance with qualifications and experience within the ranges: Senior Research Fellow: $A32,679 — $A38,980 p.a., Research Fellow: $A23,394 — $A30,734 p.a.; Postdoctoral Fellow Grade 1 (a fixed point on scale) $A20,164 — $A23,100 p.a. Current exchange rate is $A1 = UK62p.

Appointment as Senior Research Fellow/Research Fellow will be for up to three years initially with the possibility of extension after review to maximum of five years; as Postdoctoral Fellow for one or two years initially with possibility of extension to maximum of three years.

Grants are provided towards travel and removal. Assistance towards housing is given to an appointee from outside Canberra. Eligible appointees will be required to join the Superannuation Scheme for Australian Universities. The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Further information and application details are available on request from Heads of Departments, from the Registrar of the University, or from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Prospective applicants are encouraged to write for further information before lodging applications which close with the Registrar of the University, GPO Box 4, Canberra, ACT 2601, Australia, on *16 March 1984*. (W723)A

INSTITUTE OF CANCER RESEARCH AND ROYAL MARSDEN HOSPITAL — Surrey

JOINT DEPARTMENT OF PHYSICS

MEDICAL RADIATION PHYSICIST

at Senior Lecturer level: A vacancy has arisen following the appointment of Dr R P Parker to the Chair of Medical Physics at Leeds. The person appointed will hold a senior position in this large, integrated service and research department and will be expected to undertake research, service and teaching responsibilities in the physics of radio-therapy and radiodiagnosis. The organisation is well equipped for both clinical and scientific work and there is special provision for research funding on a peer-review basis. Members of the department work in close association both with clinicians in the Hospital and with scientific colleagues in other sections of the Institute. Salary in scale £13,515 — £16,925 pa plus London Allowance of £1,186 pa.

Applications in duplicate should give full details of qualifications and experience with the names of two persons familiar with the candidate's work. These should be sent to: The Personnel Officer, The Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting Ref: 300/G/40. Closing date for applications 24th February, 1984.

Further details can be obtained by telephoning Mrs Louise Parkes, Physics Department, Royal Marsden Hospital, Sutton. Tel. 01-642 6011, ext 347. (1109)A

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF CHEMISTRY

RESEARCH ASSOCIATE

Applications are invited from candidates possessing or anticipating a 1st Class or 2(i) Honours degree in Chemistry for a Research Associateship funded by the Cancer Research Campaign. Appointee will undertake research work in collaboration with Dr P L Coe on The Synthesis of Tamoxifen Analogues.

Successful candidate may be permitted to register for a higher degree on a part-time basis.

Post tenable for up to three years from 1 April 1984.

Salary on the Research Associate 1B scale £6,310-£8,530 plus superannuation.

Starting salary will depend on age, experience and qualifications.

For further particulars phone 021-472 1301 ext 2559, quoting reference F1.

No formal application form. Three copies of application, including full Curriculum Vitae and naming three referees to Assistant Registrar, (Science and Engineering), PO Box 363, Birmingham B15 2TT by 17 February 1984. (1141)A

MEDICAL RESEARCH COUNCIL

DEVELOPMENTAL NEUROBIOLOGY UNIT

Applications are invited for a

SHORT-TERM NON-CLINICAL SCIENTIFIC POST

to join a team in this Unit studying factors affecting neural development especially in culture. Background in protein separation techniques, membrane biochemistry and immunology, and experience in tissue culture are desirable. Candidates, with training in neurochemistry or cell biology, of immediately postdoctoral or equivalent status will be preferred. The appointment will be for 3-5 years. Renumeration will be at an appropriate point on the scales for University non-clinical academic staff.

Applications together with a full cv and the names of two professional referees should be sent to Robert Balazs, MRC DNU, 33 John's Mews, London WC1N 2NS (Tel: 01-242 1496) by 27 February 1984.

There is an immediate vacancy for the post of a Technician to assist in a research programme in cellular and developmental neurobiology. Applicants should have laboratory experience in biochemistry and some knowledge of tissue culture techniques and cell biology, a degree would be an advantage.

Starting salary, depending on experience, will be in the range of £5,491 — £7,747 + £932 London Weighting. Please apply with cv and the names of two professional referees to Robert Balazs at the address above. (1105)A

MRC RADIOBIOLOGY UNIT, HARWELL

TUMOUR BIOLOGIST/IMMUNOLOGIST

Applications are invited for a Short Term Non-Clinical Scientific post in this Medical Research Council Unit tenable for 3 years, to work with a group of scientists studying the effects of radiation and drugs on tumour systems. Candidates of immediately post-doctoral or equivalent status will be preferred. It is expected that the successful applicant will have some research experience in at least one of the fields of vascular physiology, experimental tumour therapy or monoclonal antibody production.

Salary and conditions of service according to MRC non-clinical scientific scales. Hostel accommodation or housing may be available.

Please write or telephone if you would like further information about this post. Applications, together with curriculum vitae and the names of two referees, should be sent to the Personnel Officer, MRC Radiobiology Unit, Harwell, Didcot, Oxon OX11 0RD, Tel 0235 834393. Closing date February 27th 1984.

(1132)A

SOUTH MANCHESTER HEALTH AUTHORITY
CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE
PATERSON LABORATORIES
LABORATORY TECHNICIANS

Required to join a new Molecular Biology team studying the role of Epstein-Barr virus in human cancer.

1. Research Technician (PL/84/4) Applicants should have a sound practical knowledge of relevant techniques including eg tissue culture, plasmid preparation, gel-electrophoresis, nick-translation and sequencing. Candidates qualified to degree or HNC standard will be preferred.

2. Junior Research Technician PL/84/5) The team also require a junior to assist, initially with routine matters such as maintenance or cells, preparation of stock solutions etc. The post would suit a school leaver with A levels in science. Day release to further qualifications will be available.

3. Part-Time Technician (PL/84/6) There are also vacancies for two part-time technicians, preferably with experience in molecular biology as indicated above. These posts will suit applicants wishing to use their experience on a part-time basis.

Salaries according to age and experience: Research Technician £5491 — £7747 pa. Junior Research Technician £3456 — £4818 pa.

Applications, enclosing a SAE, should be sent to the Laboratory Manager, Paterson Laboratories, Christie Hospital and Holt Radium Institute, Wilmslow Road, Withington, Manchester M20 9BX. Closing date 12 February 1984.

Wir über uns:
BOEHRINGER MANNHEIM
gehört zu den ersten Adressen der forschenden pharmazeutischen Industrie.
Jeder 5. Mitarbeiter ist bei uns in der Forschung und Entwicklung tätig.

Unser Forschungszentrum Biochemie befindet sich in reizvoller Lage in Tutzing am Starnberger See, südlich von München.

Unsere rasch wachsende Forschungsgruppe Mikrobiologie besteht aus qualifizierten Spezialisten verschiedener Disziplinen. Für die Leitung einer weiteren Arbeitsgruppe suchen wir einen promovierten

Molekular- oder Zell-Biologen

Zielsetzung der Gruppe ist die Entwicklung von therapeutisch wirksamen Proteinen.

Von unserem neuen Mitarbeiter erwarten wir eine molekularbiologische Ausbildung mit breiter experimenteller Erfahrung in DNA-Neukombinationstechniken: Klonierung und Expression von Genen in Säugetierzellen. Am besten paßt zu uns ein Mitarbeiter mit Teamgeist und Eigeninitiative.

Wenn Sie diese anspruchsvolle Aufgabe reizt, senden Sie uns bitte zur Gesprächsvorbereitung Ihre Bewerbungsunterlagen (Zeugnisse, Lebenslauf und Lichtbild).

UNIVERSITY OF MANITOBA
DIVISION OF HUMAN GENETICS
MOLECULAR GENETICIST

The Division of Human Genetics of the Faculty of Medicine invites applications for a full time Assistant Professor to commence by July 1, 1984. Preference will be given to individuals with demonstrated research experience in molecular genetics using recombinant DNA technology on mammalian systems, particularly in the area of genome organization, control of gene expression or gene mapping. A PhD, postdoctoral training and potential for an independent career as an experimental scientist are prerequisites.

An interest in developing expertise and a desire to be an effective educator are desirable qualities. The position is open to both women and men. Both women and men are encourged to apply. In accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada.

For full consideration send a concise description of projected research goals and interests, names of at least 3 individuals for letters of reference, and a curriculum vitae to: Dr. P. J. McAlpine, Division of Human Genetics, Faculty of Medicine, University of Manitoba, 770 Bannatyne Avenue, Winnipeg, Manitoba, Canada R3E 0W3. Deadline for receipt of applications: March 1, 1983. (NW254)A

ACADEMIC APPOINTMENT IN IMMUNOLOGY

The position is within the Immunology Research Center. The successful candidate will be expected to conduct an independent research program in fundamental or applied Immunology. Opportunities exist as well to participate in research programs already underway in the Center or at the Institut, to supervise and train graduate students, to become involved in production activities and/or to assume administrative duties.

QUALIFICATIONS: A candidate must have obtained a PhD or the equivalent from an accredited university in Canada or elsewere and must have a training in Immunology. Preference will be given to candidates with post-doctoral or other experience indicating that the candidate can pursue his or her research autonomously. Priority will be given to Canadian citizens and permanent residents of Canada. The candidate is expected to possess or to be willing to acquire a working knowledge of French.

LEVEL OF APPOINTMENT: Rank will be determined on the basis of the qualifications and experience and the salary will be according to the scale presently in effect at Institute Armand-Frappier (University of Quebec).

TO APPLY: Send your *curriculum vitae* including a list of publications, 3 letters of recommendation and any other pertinent information before February 29, 1984, to: Service des ressources humaines, Institut Armand-Frappier, 531 boulevard des Prairies, Case postale 100, Laval-des-Rapides, Laval, Québec H7N 4Z3.

(NW208)A

POSITIONS OPEN

The Hellenic Institute Pasteur is seeking to fill the following positions:
- An experienced Virologist PhD degree or MD having an experience in Virology, expected to assume responsibility of a research program.
- An experienced Parasitologist MD or VD having an experience in the entomological area, expected to assume responsibility of a research program on the Leishmaniasis.
- One Immunologist PhD degree or MD having an experience in the area of immunological techniques, expected to actively participate to a research program.

The candidates should be of Greek nationality.

Please write or call for additional information to the:
Secretary

MICHIGAN STATE UNIVERSITY

RESEARCH ASSOCIATE POSITIONS (2):

Veterinarian, DVM (possible PhD or MS given right experience) in biochemistry, immunology, microbiology or genetics. Immediate openings for two individuals in a University based biotechnology program dealing with domestic animal lymphokines, including interferon. Full time research positions — funded three year program.

Candidates must be experienced in cell culture, gene cloning and macromolecule purification. Candidates must be clinically innovative and have experience in dealing with domestic animals in a research setting. Expertise in basic biomedical research is essential. Salary dependent upon experience.

Applications should consist of curriculum vitae, statement of research and clinical experiences and interests and list of three references. Michigan State University is an affirmative action/equal opportunity institution.

Applications and inquiries should be directed to: Dr Robert W Bull, Department of Medicine, Michigan State University, East Lansing, Michigan 48824-1317. Telephone: (517) 355-4616. (NW255)A

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

(UNIVERSITY OF LONDON)
Keppel Street,
London WC1E 7HT

DEPARTMENT OF MEDICAL MICROBIOLOGY

POSTDOCTORAL RESEARCH FELLOW

is required for appointment up to three years to join a group working on the development and properties of viral peptide vaccines. The research will be concerned initially with the enhancement and analysis of cellular immune responses to viral polypeptides synthesized following examination of the nucleotide sequence of the hepatitis B genome. This work will be extended at a later date to other viral systems, including hepatitis A, herpesviruses and the flaviviruses. Preference will be given to candidates with experience in cellular immunology. Salary within the range £7190 — £11,615 plus £1186 London Weighting per annum. Applications consisting of full curriculum vitae and naming two referees should be submitted to the Senior Assistant Secretary at the above address. (1120)A

INSECT NEUROBIOLOGIST

Full-time, tenure-track appointment at the rank of assistant professor. We will seek candidates having research interests in areas such as: integrative functions of the insect CNS, neuroendocrine mechanisms, neurogenetics, neurodevelopment, neuron physiology and pharmacology. Appointee will teach annual undergraduate course in general insect physiology and conduct graduate seminars. Applicants should have a Ph.D. and should demonstrate outstanding potential for research and teaching.

Applications should include the following: (1) Curriculum vitae, academic transcripts and evidence of teaching skills and experience; (2) bibliography and selected reprints or manuscripts; (3) statement of research objectives and approaches proposed; (4) names and addresses of at least three people who can provide recommendations. Submit all materials by 1 April, 1984, to E S Sylvester, Chair, Department of Entomological Sciences, 201 Wellman Hall, University of California, Berkeley Calif. 94720. The University of California is an Equal Opportunity, Affirmative Action Employer. (NW264)A

LABORATORY Scientific Officer required to assist in a 3 year research project funded by the Multiple Sclerosis Society to investigate mechanisms of immune mediated demyelination in CNS. Candidates must have HNC or equivalent qualification, with experience in light and electron microscopy. Experience in immunocytochemical techniques an advantage. Initial salary in range: £5,491 — £6,144 plus £1,042 London Weighting. Apply in writing to the Secretary, United Medical and Dental Schools, Guy's Hospital Medical School, London Bridge, London SE1 9RT, quoting Ref. AD2. (1130)A

UNIVERSITY OF SOUTHAMPTON

PROFESSORIAL MEDICAL UNIT

RESEARCH ASSISTANT

A suitably experienced graduate is required to assist in the characterisation of autoantibodies to insulin in the above department, which maintains strong connections with the adjacent Tenovus Immunology Laboratories. Broad experience in immunological methods is important, and previous involvement in monoclonal technology would be an advantage.

Salary, according to experience, up to £8,530 pa.

Applications, including cv and the names of two referees, should be sent to Dr T J Wilkin, Professorial Medical Unit, Level D, South Laboratory and Pathology Block, Southampton General Hospital, Tremona Road, Southampton SO9 4XY, telephone (0703) 777222 ext 4291, by 20 February, 1984. (1111)A

MRC RADIOBIOLOGY UNIT, HARWELL

IMMUNOLOGIST

Applications are invited for a Sh Term Non-Clinical Scientific pos this Medical Research Council U tenable for 3 years, to work wit group of scientists studying effects of radiation, and t application of monoclor antibodies in tumour systems Candidates of immediately po doctoral or equivalent status will preferred. It is expected that t successful applicant will have so research experience in the field monoclonal antibody production.

Salary and conditions of serv according to MRC non-clini scientific scales. Hostel accomn dation or housing may be availabl

Please write or telephone if y would like further information ab this post. Applications, together w curriculum vitae and the names two referees, should be sent to Personnel Officer, MRC Rad biology Unit, Harwell, Didcot, O OX11 0RD, Tel 0235 834393. Clos date February 27th 1984.
(1133)A

VETERINARY Anatomist. Assist professorship, July 1, 1984 at Io State University for PhD or DV MS. Participation in teachi preferably in gross anatomy, development of independent resea program or active collaboration current research are expected. Sal commensurate with qualificati Send résumé and three letters recommendation to: Dr Jean Carithers, Department of Veterin Anatomy, Iowa State Univers Ames, Iowa 50011, before March 1984. Iowa State University is Equal Opportunity/Affirmat Action Employer. (NW258)A

IMPERIAL COLLEGE O SCIENCE AND TECHNOLOGY

DEPARTMENT OF BIOCHEMISTRY

RESEARCH TECHNICIA (Grade 5)

A Research Technician (grade 5 required to work with Dr K O'H on the effects of gene expressio Drosophila melanogaster of chro some rearrangements induced hybrid dysgenesis. The approache be used will include Drosophila g tics and recombinant D techniques. Experience in these a is desirable but not essential.

The appointment is funded b MRC project grant to run October 1986, and the positio available immediately. Salary is the Technical Grade 5 scale (£6 — £6,689 plus £1250 pa Lon Allowance).

Suitably qualified candid should send a full curriculum v and the names of two referees to I O'Hare, Department Biochemistry, Imperial College Science and Technology, Lon SW7 2AZ. (1119)

The University of Agriculture provides agricultural education at an academic level in the Netherlands. The university has a staff of approximately 2800 and some 6000 students attending more than 70 vocational courses and conducting research. The registry comprises administrative offices, the library and a computer department.

WAGENINGEN
LANDBOUWHOGESCHOOL

Research assistant m/f

for a to be established section Plant Cell Biology for a five-year period

Duties

To stimulate plant cell biological research, the Faculty has decided to add a section Plant Cell Biology to the vocational group Molecular Biology Amongst the duties are developing plant cell biological research within the vocational group Molecular Biology. Such research shall form part of the WUB biotechnological group "Plant cell and Animal cell", in which six other University groups participate. It is expected that, after an initial period, you will conduct graduate studies and laboratory work and that graduate students can participate in research in obtaining their degree.

Requirements and benefits

You are a (molecular) (cell) biologist, experienced in plant cell biological research and an obvious interest in practical agricultural research application. You will collaborate closely with colleagues of various University vocational groups and with agricultural research institutions.
We offer a salary in accordance with Civil Service standards of Dfl. 6.561,- gross per month, depending on age, qualifications and experience.
Vacancy no. 83-066/2407.

Information regarding this position may be obtained from Prof. Dr. A. van Kammen, telephone 00 31 8370 82036/7.

The personnel policy of the University of Agriculture is aimed at achieving a reasonable balance between male and female staff members. In view of the fact that the number of women employed remains behind, women in particular are encouraged to apply. In the event of matched qualifications, preference shall be given to female applicants.

Your application should be addressed within fourteen days, to the head of the Personnel Department of the University of Agriculture, P.O. Box 9101, 6700 HB Wageningen, the Netherlands.
State the Vacancy number in the upper left hand corner of your letter and enveloppe.
A job description can also be obtained at this address. The University application code shall apply.

(W702)A

POSTDOCTORAL POSITION:

MOLECULAR BIOLOGY OF TUMOUR PROMOTION

Suitable for a PhD or MD with research experience who will join our program employing recombinant DNA technology to investigate effects of TPA on mammalian cells. Supported by the Terry Fox Training Grant Program established by the National Cancer Institute of Canada.

Send CV and references to Dr. David Denhardt, Cancer Research Laboratory, University of Western Ontario, London, Ontario, N6A 5B7 Canada. (NW257)A

SOUTH MANCHESTER HEALTH AUTHORITY
CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE
PATERSON LABORATORIES

RESEARCH TECHNICIAN

For experimental work on the biology of self-renewing systems in the Section of Epithelial Kinetics. Candidates should have a degree or HNC equivalent qualification in Biology: some experience or cell culture techniques preferred.

Salary according to age and experience £5491 — £7747.

Applications, enclosing a SAE to the Laboratory Manager, Paterson Laboratories, Christie Hospital and Holt Radium Institute, Wilmslow Road, Withington, Manchester M20 9BX, quoting reference PL/84/3. Closing date 12 February 1984.
(1126)A

THE SCHOOL OF PHARMACY
UNIVERSITY OF LONDON
Neuropharmacology Research Group
DEPARTMENT OF PHARMACOLOGY

RESEARCH TECHNICIANS

TWO Grade 4 technical posts available for up to 5 years from date of appointment.

1. ASSISTANT ELECTRONICS TECHNICIAN

to assist in the design and construction of electronic apparatus under the direction of the electronics experimental officer. The preferred applicant should have an interest in microprocessor and/or computer applications. Ref: AET/1.

2. TISSUE CULTURE TECHNICIAN

to assist in studies on nerve cells in culture. The applicant should have an interest in tissue culture techniques and their application. Ref: TCT/2.

Practical experience for both these posts, supported by appropriate qualifications, essential. Salary £5,826 — £6,702 pa + LW £1,250 pa. 5 weeks + public holidays. Season ticket loan scheme.

Enquiries to Mr G B Withers (tel: 01-837 7651 ext 17). Application forms from: Personnel Officer, The School of Pharmacy, 29/39 Brunswick Square, London WC1N 1AX. (1137)A

HOUGHTON POULTRY RESEARCH STATION

GRANT-AIDED BY THE AGRICULTURAL & FOOD RESEARCH COUNCIL

IMMUNOLOGIST

The Institute is seeking an Immunologist in the Microbiology Department to provide immunological input to a multi-disciplinary project on the use of the techniques of genetic manipulation to produce novel vaccines for poultry. Specific duties will be to examine the local and systemic immune response of the chicken to viral and other antigens presented to mucosal surfaces but the appointee will also be expected to develop an interest in other immunological problems that are being investigated on the Station.

Applicants should have a first or upper second class honours degree in a biological subject and preferably a PhD, and will have had several years' post-graduate experience in immunology. At least 2 years relevant post graduate research experience is required for HSO grading; 4 years for SSO.

The appointment will be made in the Higher Scientific Officer or Senior Scientific Officer grade, according to experience. Salaries HSO: £7,149 x 6 to £9,561; SSO: £8,970 x 7 to £11,476.

For further details and application form please contact the Secretary, John Andrews, at Houghton Poultry Research Station, Houghton, Huntingdon, Cambs PE17 2DA. Tel St Ives (0480) 64101. (1088)A

MEDICAL RESEARCH COUNCIL
NEUROENDOCRINOLOGY UNIT
Newcastle upon Tyne

RESEARCH OFFICER (Electronics)

The appointee will be responsible for the design, construction and maintenance of electronic equipment to be used in biophysical investigations of the properties of neurones and neurosecretory cells. Design tasks will include: very low-level current detection circuitry; high-speed multichannel optical recording devices; computer-controlled stimulation equipment; instrumentation amplifiers; analog signal transformation circuitry. The appointee should have some experience of computer interfacing.

Minimum requirement is a university degree, HNC or equivalent qualification, with two years relevant experience after qualification. Salary scale (due for revision) Research Officer £6204 — £8126; Senior Research Officer £8204 — £10467.

For further information contact: Dr R N McBurney, MRC Neuroendocrinology Unit, Newcastle General Hospital, Westgate Road, Newcastle upon Tyne NE4 6BE Telephone (0632) 735251.

(1124)A

The European Molecular Biology Laboratory, a research institute situated in Heidelberg, West Germany, invites applicants for the following vacancy

TECHNICAL ASSISTANT

The successful applicant will work in a group concerned with the problems of membrane protein traffic in animal cells. The techniques employed include cell fractionation, in vitro protein synthesis, biochemical as well as immunological isolation and characterization of membrane proteins. Some knowledge of nucleic acid methodology would be advantageous.

Appropriate training and experience in biochemical technology and analysis is essential. Preference will be given to candidates having experience in the application of immunological tools in biochemistry and cell biology (monoclonal antibody production, affinity chromatography, immuno-fluorescence microscopy etc.) A working knowledge of English is essential; a second language (French or German) is desirable.

An above average salary will be offered to the successful candidate. Certain allowances are payable in addition, depending on personal circumstances. An initial contract of 3 years' duration which can be renewed, will be offered.

Please write briefly for an application form, quoting ref. No. 84/3 to:
EMBL, Personnel Section,
Postfach 10.2209,
D-6900 HEIDELBERG
(W711)A

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF PHARMACY

TEMPORARY LECTURESHIP IN PHARMACEUTICAL AND MEDICINAL CHEMISTRY

Applications are invited for this appointment. The successful applicant will be required to contribute to undergraduate and post graduate teaching in Pharmaceutical and Medicinal Chemistry as well as to undertake research in these areas.

The appointment is for three years and preference may be given to applicants with relevant experience in medicinal chemistry and whose research interests complement those currently active in the department. These are summarised in the further particulars.

Salary in the range £7,190 to £14,125 per annum.

Further particulars and applications forms, returnable not later than 9th March 1984 may be obtained from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD. Ref No 917. (1128)A

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF GENETICS

Applications are invited for a

UNIVERSITY LECTURESHIP

vacant on 1 October 1984.

The scale of stipends is at present £9,875 a year, rising by annual increments to £15,085, or, if the person appointed is ordinarily resident in College, £9,776 rising to £14,986.

Well qualified applicants from any field of genetics will be considered but, all other things being equal, preference may be given to a plant geneticist.

Further particulars may be obtained from: The Secretary of the Appointments Committee of the Faculty Board of Biology 'A', Department of Zoology, Downing Street, Cambridge CB2 3EJ, to whom applications should be sent as soon as possible and in any case to reach him not later than 1 May 1984. (1115)A

REGIONAL CYTOGENETICS LABORATORY EAST BIRMINGHAM HOSPITAL

BASIC GRADE SCIENTIFIC OFFICER

Required in the above laboratory. Experience in cytogenetics or cell culture desirable.

Salary range, depending on experience and qualifications £5,681 — £8,349 per annum.

For application form and job description please contact Regional Cytogenetics Laboratory, East Birmingham Hospital, Bordesley Green East, Birmingham B9 5ST. Tel: 021-772 4311 ext 4354. (1129)A

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

DEPARTMENT OF IMMUNOLOGY

POSTDOCTORAL RESEARCH ASSISTANT

required to work with a team actively studying rheumatoid arthritis and autoimmune thyroiditis. Initially the project will involve production, characterization and functional activity of human monoclonal autoantibodies.

The candidate must have considerable experience of tissue culture techniques. The appointment is for 3 years in the first instance, and salary is according to age, qualifications and experience within the range £8,376-£12,801 pa inclusive of London Allowance.

Applications to include the names of two referees, should be sent to Professor I M Roitt, Department of Immunology, The Middlesex Hospital Medical School, Arthur Stanley House, 40-50 Tottenham Street, London W1P 9PG. (1101)A

THE UNIVERSITY OF BRITISH COLUMBIA

GRADUATE STUDIES IN CHEMISTRY

Applications are invited from candidates with high academic records who wish to pursue further studies towards the MSc and PhD Degrees in Chemistry. Excellent research facilities are available in all areas of modern Chemical Science, ranging from Biological Chemistry to Chemical Physics. Teaching and research assistantships are available for all students in the programme. Stipends up to $20,800 are available to highly qualified students who hold scholarships; the minimum stipend for 1983/84 is $11,000.

Application forms and further particulars may be obtained from: Dr L Weiler, Professor and Head, Department of Chemistry, The University of British Columbia, 2036 Main Mall, Vancouver, BC, Canada V6T 1Y6. (NW773)A

IMPERIAL CANCER RESEARCH FUND RESEARCH OFFICER/SENIOR RESEARCH OFFICER

required to run a cytogenetics service at the ICRF Medical Oncology Unit, St Bartholomew's Hospital London, and to work in close collaboration with the Human Cytogenetics Laboratory at the main laboratories in Lincoln's Inn Fields.

Degree or equivalent plus experience in human cytogenetics essential.

Salary range including London Weighting, £7454 to £11,717.

For further details and application form write or telephone Ms S M Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2 on 01 242 0200 ext 305, quoting reference 45/84. (1125)A

SCIENTIFIC DIRECTOR

Large regional blood center searching for a Scientific Director for the direction of an expanding research and development program in collaboration with academic departments of the University of Connecticut Health Center. Significant internal research support and faculty appointment at University of Connecticut Health Center and/or Yale University School of Medicine available to qualified applicants.

Applicant should possess an MD or PhD degree and have at least five years of research experience at the post-doctorate level with demonstrated ability to perform independent research and direct the research of others. Salary is competitive and a complete benefit package is available.

Submit Curriculum Vitae and research plans to Dr Ritchard Cable, Director, American Red Cross Blood Services, Connecticut Region, 209 Farmington Avenue, Farmington, Ct 06032. (NW267)A

University College London

POSTDOCTORAL POSITION IN RECEPTOR RECONSTITUTION

Applicants are invited for work on reconstitution of neurotransmitter receptors into lipid bilayers. It is expected that the primary approach will involve single ion channel recording from such preparations. The laboratory has long term MRC support (to D Colquhoun and S G Cull-Candy) and is well-equipped for this work, which will involve collaboration with Professor E A Barnard of Imperial College London.

A salary in the range of £8,376 — £10,611 will be available from October 1984.

Applications, together with cv and names and addresses of the referees should be sent to Prof D Colquhoun Dept of Pharmacology, University College London, Gower Street London WC1E 6BT, UK. (1100)A

COMMITTEE FOR THE FACULTY OF BIOLOGY 'A'

DEPARTMENT OF ZOOLOGY

UNIVERSITY LECTURER

Neurobiologist required experienced in the analysis of neurons in the vertebrate brain or spinal cord using modern cellular techniques. Interest in local circuit neurons is desirable but not essential. ("New Blood" post with a normal age limit of 35.)

Appointment will be for three years with the possibility of re-appointment to the retiring age. The pensionable scale of stipends if not ordinarily resident in College is £9,875 a year rising by eleven annual increments to £15,085.

Further information from the Secretary of the Appointments Committee for the Faculty of Biology 'A', Department of Zoology, Downing Street, Cambridge CB2 3EJ to whom applications (5 copies) curriculum vitae and names of three referees should be sent by 21 February 1984. (1117)A

UNIVERSITY OF OXFORD

READERSHIP IN ATMOSPHERIC PHYSICS

In association with JESUS COLLEGE

Applications are invited for the above post, to be filled from October 1st 1984. The post carries the headship of the Department of Atmospheric Physics and the successful candidate may be offered a fellowship at Jesus College.

Details of the University and College appointments may be obtained from the Chairman of the Interdepartmental Committee for Physics, Professor K W Allen Department of Nuclear Physics Keble Road, Oxford, to whom completed applications (six typed copies one for overseas candidates) should be sent by February 28th. (1116)A

UNIVERSITY OF EAST ANGLIA
Norwich

POSTDOCTORAL RESEARCH ASSOCIATE

in Physical Organic Chemistry, required in the School of Chemical Sciences. The post is funded jointly by SERC and ICI (Pharmaceuticals Division), to investigate potential pro-drugs based on masked lactones. The appointment is for one year, and will commence April 1984, or as soon as possible thereafter. The starting salary will be up to £8,530 per annum. Applicants should have experience in techniques of physical organic chemistry, particularly kinetic procedures, and in organic synthesis, and be prepared to develop interests in the biochemical and medicinal chemical fields. The work will be carried out at Norwich.

Applications with curriculum vitae and names and addresses of two referees to be sent to:- Dr C.D. Johnson, School of Chemical Sciences, University of East Anglia, Norwich NR4 7TJ as soon as possible. (1108)A

ASTRONOMY FACULTY position. The Department of Physics & Astronomy invites applications for one or two tenure-track faculty positions starting September 1984 at a professorial rank commensurate with the qualifications of the candidate. The position is open to any astronomer with expertise in millimeter wavelength observations, who will be expected to conduct an active research program at the Five College Radio Astronomy Observatory. Candidates with exceptionally strong credentials in related observational programs, eg infrared, will also be given consideration and are urged to apply. A résumé and the names of three references should be sent to Dr David Van Blerkom, Astronomy Program Chairman, GRC Tower B, University of Massachusetts, Amherst, MA 01003. Deadline for submission of application is March 15, 1984. The University of Massachusetts is an Affirmative Action/Equal Opportunity Employer.
(NW262)A

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS

Applications are invited for the post of
LECTURER in PHARMACOLOGY.

The duties of the post are to teach in the BSc Honours Pharmacology course and to engage in research in Pharmacology.

Initial salary within the range £7,190 — £9,425 per annum on a scale rising to £14,125 per annum.

Applications, together with the names of three referees, should be received not later than 20 February, 1984 by the Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/216/N (1118)A

THE INSTITUTE OF ZOOLOGY, THE ZOOLOGICAL SOCIETY OF LONDON

POSTDOCTORAL RESEARCH ASSISTANT

required to study surface antigens of gametes and early embryos in mammals. Experience of appropriate biochemical and immunological techniques is essential.

POSTDOCTORAL RESEARCH ASSSISTANT

required to investigate ultrastructural aspects of sperm maturation and embryo development. Experience of electron microscopy and immunocytochemistry is essential.

LABORATORY TECHNICIAN

required to work on the production of monoclonal antibodies raised to mammalian gametes. Experience of tissue culture is essential and of monoclonal development is desirable.

The appointments are within the MRC/ARC Comparative Physiology Research Group and are for two years initially, commencing from April 1984, with possible extension for a further two years. Salary will be appropriate to age, qualifications and experience in relation to the scales for research assistants or research technicians in the University of London.

Please apply in writing by providing c.v. and names and addresses of two referees to the Establishment Officer, Zoological Society of London, Regent's Park, London NW1 4RY, to arrive before 15 February 1984. (1104)A

UNIVERSITY OF CAMBRIDGE
DEPARTMENT OF GENETICS

POSTDOCTORAL POSITIONS

Applications are invited for a postdoctoral post funded by SERC from 1 April 1984 to study the genetics and evolution in the rDNA multigene family in Drosophila.

Applications, including curriculum vitae and names of two academic referees, to Dr G A Dover, Department of Genetics, Downing Street, Cambridge CB2 3EH.
(1114)A

NEUROSCIENCES AT BAYLOR COLLEGE OF MEDICINE

Baylor College of Medicine offers an interdepartmental Neuroscience Program for students interested in advanced study leading to the PhD in neuroscience. Applications must be completed by 1 April 1984, and applicants will be notified regarding admission and financial support by 15 May 1984.

Information regarding the program curriculum, faculty, research opportunities, and application procedures may be obtained from:

Scott F Basinger, PhD, Director, Predoctoral Program in Neuroscience, Cullen Eye Institute, Baylor College of Medicine, Texas Medical Center, Houston, Texas 77030.
(NW256)A

THE UNIVERSITY OF MANCHESTER

Research Assistants in Radio Astronomy

Applications are invited for appointments as Post-Doctoral Research Assistants in the Nuffield Radio Astronomy Laboratories, Jodrell Bank. Research Assistants are expected both to carry out their own research and assist with existing research activities. Current areas of research include quasars and active galaxies; radio spectral line studies of galaxies and stars; pulsars; and the isotropy of the microwave background radiation. The appointments are tenable from August 1st, 1984 initially for a period of one year with a good possibility of extension up to a maximum of 3 years. A number of appointments are available immediately.

Salary range p.a.: £7,190 — £11,615 (Superannuation) depending upon age and experience.

Enquiries should be addressed to: The Director, Nuffield Radio Astronomy Laboratories, Jodrell Bank, Macclesfield, Cheshire SK11 9DL. (1138)A

THE UNIVERSITY OF WAIKATO
New Zealand

OFFICE OF VICE-CHANCELLOR

(Re-advertisement)

The position of Vice-Chancellor of the University of Waikato will become vacant on 1 February 1985, following the retirement of Dr D R Llewellyn, who has held the office since 1964 as the first Vice-Chancellor of the institution.

The Vice-Chancellor is the academic and administrative head of the University responsible to the Council.

The Council invites enquiries from or suggestions concerning suitably qualified persons. Correspondence should be marked *Personal and Confidential* and should be addressed to the Chancellor at the following address: University of Waikato, Private Bag, Hamilton, New Zealand.

This position is being readvertised and applications will now close on *30 April 1984.* (W706)A

ETH

INSTITUTE OF ASTRONOMY
Zurich, Switzerland

RESEARCH ASTRONOMER

Applications are invited for a position on the regular scientific staff of the Institute of Astronomy, ETH Zurich (Swiss Federal Institute of Technology). Candidates should have earned a doctorate in astronomy or a closely related physical science. Their research record should include experience in plasma astrophysics or solar radio astronomy.

The successful applicant should perform independent research work within the framework of the current research programs of the Institute of Astronomy, preferably with an emphasis on research related to solar radio astronomy.

Initial appointment will be for a period of three years, but can be renewed. The salary will depend on the qualifications of the applicant, according to the regulations of the ETH.

Applicants should submit curriculum vitae, list of publications, the name of two referees, and date of availability, to:

Prof. J.O. Stenflo, Director
ETH-Zentrum
CH-8092 Zurich, Switzerland.

Closing date for the applications is April 1, 1984. (W703)A

THE UNIVERSITY OF LEEDS

ASTBURY DEPARTMENT OF BIOPHYSICS

POSTDOCTORAL RESEARCH FELLOW in the Deisgn of Enzyme Inhibitors using Computer Graphics in collaboration with G D SEARLE & CO

Applications are invited for the above post for research on computer model-building and molecular mechanics studies leading to the development of enzyme inhibitors for clinical use as drugs. The project will make use of an Evans & Sutherland PS300 colour display system. Applicants should have, or be about to obtain, a PhD degree in protein crystallography, molecular graphics or related structural studies. The appointment is funded by an SERC Co-operative Research Grant and is for a fixed period of up to two years.

Salary on the IA Range for Research and Analogous Staff (£7,190-£11,615), according to age, qualifications and experience.

Informal enquiries may be made to Dr A J Geddes or Professor A C T North of the University of Leeds, telephone (0532) 431751 ext 7088 or 6130.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference no 42/5/D. Completed applications should be returned to the Registrar as soon as possible.

(1145)A

UNIVERSITY OF YORK

DEPARTMENT OF BIOLOGY

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post which is funded by the Medical Research Council. The post is for a period of three years and is available immediately.

The work, with Dr D C S White and in collaboration with Dr D R Trentham FRS and Dr M R Webb both of NIMR, Mill Hill, will involve a study of the kinetics of the reactions following the hydrolysis of ATP in intact muscle fibres, using phosphate-water oxygen-exchange as the probe. Experience in kinetics and/or enzyme mechanisms is desirable.

Salary range: £7,190 — £8,530 pa.

Four copies of applications, including a full curriculum vitae and the names of two referees should be sent as soon as possible to the Registrar, University of York, Heslington, York YO1 5DD. Please quote reference number 11/6189.

(1144)A

THE UNIVERSITY OF ADELAIDE

invites applications from both men and women for the following position:

POSTDOCTORAL FELLOW IN APPLIED GEOPHYSICS (S8805) (FOR MATHEMATICIAN, PHYSICIST OR ENGINEER)

in the field of airbone magnetic surveys. The position will be in the Department of Economic Geology which will be amalgamated with the Department of Geology and Mineralogy in 1985, to form a single Department of Geology.

The appointee will participate with Professor D Boyd and a small research group in the development of a practical system of computer aided interpretation of digital aeromagnetic data which is being applied to problems in mineral exploration and geological studies.

Applicants should hold a PhD degree in one of the three fields of mathematics, physics or engineering, and should have used computing in postgraduate studies and be interested in solving complex real problems. Experience in geophysics is an advantage but is not essential.

The person appointed should take up the post before the end of June 1984. The appointment will be for one year in the first instance and, subject to the satisfactory performance of duties, will be extended for a further two years.

Further information on the duties of the position may be obtained from Professor D Boyd (telephone: (08) 228 5843) and Dr P Brooker (telephone (08) 228 5842) or telex: UNIVAD AA89141.

Further information about the general conditions of all appointments may be obtained from the Senior Assistant Registrar (Personnel) of the University.

Salary per annum: $A20164 × 5 — $23100.

Applications, in duplicate, quoting reference numbers and giving full personal particulars (including citizenship), details of academic qualifications and names and addresses of three referees, should reach the Senior Assistant Registrar (Personnel) at the University of Adelaide, GPO Box 498, Adelaide, South Australia 5001 (telex: UNIVAD AA89141), not later than 1 April 1984.

The University reserves the right not to make an appointment or to appoint by invitation. (W731)A

WANTED AND FOR SALE

Scientific and Technical Reviews.

(W708)Q

FELLOWSHIPS

ONE YEAR FELLOWSHIP
(from 75,000 to 180,000 FF)
AVAILABLE IN PARIS
for a Biochemist to work on growth factors. Send application to Dr BARRITAULT for Jan.'85 before March 1st at: INSERM U. 118— 29 rue Wilhem 75016 PARIS — France.

(W727)E

THE UNIVERSITY OF AUCKLAND New Zealand

RESEARCH FELLOWSHIP IN GEOTHERMAL RESERVOIR ENGINEERING

Applicants should have a PhD in engineering or applied mathematics and some experience in reservoir modelling is desirable. The Fellowship will be for one year in the first instance with the probability of renewal for at least 2 further years.

Commencing salary up to NZ$22,487 per annum. Conditions of Appointment and Method of Application are available from the Assistant Registrar (Academic Appointments), University of Auckland, Private Bag, Auckland, New Zealand, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1 0PF.

Applications in accordance with Method of Application should be forwarded to the University as soon as possible but not later than 31 March 1984. (W730)E

THE FLINDERS UNIVERSITY OF SOUTH AUSTRALIA

SCHOOL OF MEDICINE

RESEARCH FELLOWSHIP

Applications are invited fron suitably qualified persons for Research Fellowship tenable withi any of the fields represented in th School of Medicine of the University The Research Fellowship, which i available immediately, is tenabl initially for one year, bu applications may be entertained fro persons who wish to take up th position for a shorter perioc Applicants should have completed PhD degree prior to taking up th appointment, or have had equivaler research experience.

The appointment will be mad according to qualifications an experience within the salary rang $A20,164 — $A23,100. Persons wit a PhD will normally be appointed o the third step ($A21,338). A contribution will be made towarc the travel costs of the Fellow an his/her dependents in taking up th Fellowship.

Further details concerning the stal of the School and their fields c interest may be obtained from th Registrar.

Applications, including fu personal details, details of academi record and publications, outline c research interests and names an addresses of at least two referee should be lodged, in duplicate, wit the Registrar, The Flinder University of South Australia Bedford Park, South Australia 5042 by 29 February 1984. Applicant should ask their referees to forwar their reports directly to the Registra before the closing date. (W724)E

UCG Coláiste na hOllscoile Gaillimh

UNIVERSITY COLLEGE GALWAY

POSTDOCTORAL FELLOWSHIP

Applications are invited for a postdoctoral position that will soon be available in the laboratory of Dr. Frank Gannon. The successful candidate will work on the molecular cloning and manipulation of eucaryotic genes as part of a recently established active research group.

Previous experience with recombinant DNA techniques, while not essential, will be an advantage to the applicant.

Please send Curriculum Vitae to Dr. Frank Gannon, Department of Microbiology, University College, Galway, Ireland. (1135)E

UNIVERSITY OF GÖTEBORG, Göteborg, Sweden

A POST-DOCTORAL FELLOWSHIP in arterial cell and molecular biology arterial.

A post-doctoral fellowship is available for 12 months in the arterial biology group of the University of Göteborg, Göteborg, Sweden. The arterial biology group is involved in research on the cellular and molecular biology of atherosclerosis. Graduate or post-graduate training in either cell or molecular biology is required.

Post-graduates with the appropriate back-ground should write to Dr G. Bondjers, Arterial Biology Group, Medical Faculty, University of Göteborg, S-413 45 Göteborg, Sweden, enclosing a curriculum vitae, reprints and manuscripts, and the names of two referees. (W710)E

UNIVERSITY OF BIRMINGHAM

DEPARTMENTS OF ICROBIOLOGY AND GENETICS

POSTDOCTORAL ESEARCH FELLOWSHIP

plications are invited for the ve post which is funded by an C grant to Dr C W Penn (Micro- logy) and Dr C M Thomas netics). The work will involve iing and expression of antigens es of the syphilis agent ponema pallidum in Escherichia . Candidates should have a back- und in microbiology and/or bio- nistry and should preferably have e experience of recombinant A techniques, although this is not ntial.

ost tenable for up to three years n 1.4.84 or as soon as possible eafter.

alary on the Research Fellow 1A e £7,190-£11,615 plus super- uation.

SEMINARS and SYMPOSIA

TENTH EMBO ANNUAL SYMPOSIUM 1984

Control of Transcription in Eukaryotes

24—27 September 1984

EMBL Heidelberg (F.R.G.)

Invited speakers include:

M. E. Akam (Cambridge; V. G. Allfrey (New York); M. Beato (Marburg); P. Borst (Amsterdam); F. Cuzin (Nice); E. M. De Robertis (Basel); A. van der Eb (Leiden); H. Eisen (Paris); D. Gallwitz (Marburg); W. J. Gehring (Basel); F. G. Grosveld (London); I. Grummt (Würzburg); P. Gruss (Heidelberg); L. Hereford (Boston); A. Johnson (San Francisco); C. Kédinger (Strasbourg); W. Keller (Heidelberg); U. Laemmli (Geneva); T. Maniatis (Cambridge, USA); K. Nasmyth (Cambridge); M. S. Neuberger (Cambridge); C. S. Parker (Pasadena); M. Revel (Rehovot); R. G. Roeder (New York); W. Schaffner (Zürich); U. Schibler (Lausanne); W. T. Schrader (Houston); G. Schütz (Heidelberg); A. Sentenac (Gif-sur-Yvette); P. A. Sharp (Cambridge, USA); T. Shenk (Stony Brook); K. Struhl (Boston); G. Tocchini-Valentini (Rome); C. Weissmann (Zürich); N. M. Wilkie (Glasgow); K. R. Yamamoto (San Francisco); M. Yaniv (Paris)

Although the main theme of the Symposium is the control of transcription in eukaryotes, some aspects of RNA processing will also be discussed.

The Symposium will be at the European Molecular Biology Laboratory, Heidelberg, with registration on Sunday, 23 September 1984. Plenary sessions will be held in the mornings and evenings of 24 — 26 September, and the morning and afternoon of 27 September. There will be poster sessions in the afternoons of 24 — 26 September inclusive, to allow participants to present their work. It is also intended to organize informal workshops during the Symposium, the themes of which, depending on the posters received, may include inducible genes, cell-type specific gene expression, promoter organization and the structure of active chromatin.

Applications for participation, including a curriculum vitae, a brief description of current research interests, and a 1-page (DIN A 4) abstract of your poster, if you wish to present one, should be sent to: Dr. J. Tooze, Executive Secretary, EMBO, Postfach 1022.40, D - 69 Heidelberg, F.R.G.

The registration fee, which includes daily transport to the EMBL from Heidelberg during the Symposium, lunches, and the Symposium reception is DM 180, for graduate students DM 90, and for participants from industry DM 360. Participants will be accommodated in hotels in Heidelberg, and a small number of inexpensive rooms will be available in the EMBL Guest House. The registration fee does NOT cover the cost of accommodation.

Applications should reach Heidelberg by 1 June 1984. The facilities available make it necessary to restrict the number of participants to about 220 and, therefore, the Organizing Committee may be obliged to make a selection from the applications received. Those accepted will be notified by 31 July 1984 at the latest. The registration fee should NOT be sent until you have been notified of your acceptance for the Symposium.

Organizing Committee: L. Philipson (EMBL Heidelberg) — Chairman, M. Birnstiel (Zürich), P. Chambon (Strasbourg), R. Cortese (EMBL Heidelberg), H. Pelham (Cambridge), J. Tooze (EMBO). (W715)M

FOURTH INTERNATIONAL SYMPOSIUM ON RAPID METHODS AND AUTOMATION IN MICROBIOLOGY AND IMMUNOLOGY

Sponsored by: German Society of Hygiene and Microbiology (DGHM)
International Union of the Microbiological Societies (IUMS)
(1981 Washington, 1976 Cambridge, 1973 Stockholm)

BERLIN, JUNE 7-10, 1984

18 seminars with 80 invited speakers will cover:

Time realities in the evaluation of vaccines for safety and efficacy; hybridisation technology in microbiology; hybridisation technology in virology; rapid diagnosis by IgM-detection; application of monoclonal antibodies; problems of hybridoma technology; data processing in microbiology and serology; fluoroimmunoassays; bioluminescence; physical detection of microorganisms; chromatography; antigen detection; isolation of microorganisms; identification of microorganisms; antimicrobial susceptibility tests; assays of antimicrobial agents in fluids and tissues; food microbiology; environmental microbiology.

Chairmen:

A. Balows (Atlanta); T. Bergan (Oslo); J. Chidlow (London); L. Corey (Seattle); T.O. Diener (Beltsville); S. Falkow (Standord); A.A. Gershon (New York); D. Gröschel (Charlottesville); N. Guttman-Bass (Jerusalem); K. -O. Habermehl (Berlin); P. Halonen (Turku); W.J. Hausler, Jr. (Iowa City); W. Heeschen (Kiel); L. Hertzenberg (Stanford); M.R. Hilleman (West Point); H.D. Isenberg (New York); B. Jarvis (South Ruislip); L. Kaufman (Atlanta); U, Krech (St. Gallen); S. Krugman (New York); M. Lovett (Los Angeles); J.M. Matsen (Salt Lake City); C.W. Moss (Atlanta); S.W.B. Newsom (Cambridge); C.E. Nord (Stockholm); S.H.W. Notermans (Bilthoven); I. Phillips (London); K. Ryan (Tucson); A.N. Sharpe (Ottawa); T. Staehelin (Basel); A. Thore (Bromma); R.C. Tilton (Farmington); L.S. Tompkins (Palo Alto); A. Turano (Brescia); S. Ulitzur (Haifa); I. Yano (Osaka); R.H. Yolken (Baltimore); H. zur Hausen (Heidelberg).

In addition: 16 seminars of 130 contributors and additional poster sessions. The Symposium will be held at the International Congress Center Berlin in combination with an Industrial Exhibition.

Requests for the preliminary program, registration forms, and applications for scientific contributions should be sent to: **Institute of Clinical and Experimental Virology, Free University Berlin, Hindenburgdamm 27, D-1000 Berlin 45, Tel. (030) 7983696.**

Registration fee: Participants before March 1st, 1984 DM 350.-, after March 1st, 1984 DM 450.-. Students (with certification of the University) DM 120.-. Accompanying persons DM 60.-. The registration fee includes a volume of abstracts and a book of proceedings, published by Springer Verlag Berlin, Heidelberg, New York, Tokyo.

European Society for Animal Cell Technology
International Association of Biological Standardization

The joint ESACT/ IABS meeting on the PRODUCTION AND EXPLOITATION OF EXISTING AND NEW ANIMAL CELL SUBSTRATES

will be held on MAY 21st-25th 1984
in GARDONE RIVIERA, Italy

The Meeting is organized by:
"Menarini" International Foundation, Florence, Italy
Zooprophylactic Foundation, Brescia, Italy

SUBJECT AREAS: Genetic Engineering or Modification of Animal cells, Characterization of Cell Substrates.

Safety Aspects Relating to the Exploitation of Animal Cells, Oncogenes, Regulatory Proteins, Regulatory Authorities.

Production of Antibody from Hybridomas and the Scale-Up of such Systems.

Developments in Large-Scale Cell Production Equipment.

Medium Developments for Cell and Product Generation.

Serium-Free Media (Pains and Pleasures).
Downstream Processing of Materials Produced from Cultured Animal Cells.

New Product Areas (Lymphokines, Enzymes, Hormones).

Organizing Secretariat: G. F. Panina c/ o FONDAZIONE INIZIATIVE ZOOPROFILATTICHE, Via Bianchi 1, 25125 Brescia — Italy. (W649)M

INTERNATIONAL SYMPOSIUM on "RETROVIRUSES AND HUMAN PATHOLOGY"

September 25-26, 1984 — S. Terenzo di Lerici, La Spezia, Italy

INVITED SPEAKERS

M. BARBACID (USA)
A. BURNY (Belgium)
J.C. CHERMANN (France)
R. DULBECCO (USA)
R.C. GALLO (USA)
J. HILGERS (The Netherlands)
J.A. LEVY (USA)
B.A. NEXO (Denmark)
D. STEHELIN (France)
J. SVOBODA (Czechoslovakia)
R.A. WEISS (England)
J. WYKE (England)
O. JARRETT (Scotland)

PRELIMINARY PROGRAMME

W.P. Rowe Memorial Lecture
Lecture sessions on:
retroviruses and the murine model system
retroviruses and the vertebrate model systems
retroviruses and human pathology
round table discussion on:
the role of retroviruses in nature: an update
non-stop poster session,
limited to 100 participants

Deadline for abstract submission:
March 30, 1984

ORGANIZING AND SCIENTIFIC SECRETARIAT:
OLIVIERO E. VARNIER
Institute of Microbiology, School of Medicine
Viale Benedetto XV, 10
16132 GENOVA, Italy — Phone: (010) 501337 (W718)M

INTERNATIONAL SYMPOSIUM ON MONOCLONAL ANTIBODIES: BIOLOGICAL AND CLINICAL APPLICATIONS
Florence, Palazzo dei Congressi, October 16-19, 1984

Scientific Secretariat: A. Pinchera — G. Doria — F. Dammacco — A. Bargellesi

The meeting is intended to cover three broad areas of biological and clinical applications of monoclonal antibodies: Markers of the Immune System; Hormonal Receptors and Related Autoimmune Disorders; Experimental and Clinical Oncology.

The Scientific Program will consist of Invited Lecturers and Poster Sessions. A limited number of Posters will be selected for oral presentation.

Invited Speakers: L. Adorini (Italy), R. C. Bast (USA), C. A. Bona (USA), M. I. Colnaghi (Italy), P. Comoglio (Italy), G. Corte (Italy), S. Dower (USA), P. A. W. Edwards (UK), A. Falaschi (Italy), I. D. Goldfine (USA), M. F. Greaves (UK), G. L. Greene (USA), C. Grossi (Italy), S. Hakomori (USA), L. D. Kohn (USA), J. Lindstrom (USA), R. G. Lynch (USA), J. P. Mach (Switzerland), S. L. Morrison (USA), K. Rajewski (FRG), M. D. Scharff (USA), R. H. Schwartz (USA), J. Strominger (USA), J. Schlessinger (Israel), T. Tada (Japan), I. S. Trowbridge (USA), P. E. Thorpe (UK), J. C. Venter (USA), T. A. Waldmann (USA), L. N. Warner (USA).

The deadline for submission of Abstracts is June 15, 1984. For further information write to the *Organizing Secretariat:* Organizzazione Internazionale Congressi (O.I.C.), Via Gustavo Modena 19, 50121 Florence (Italy). Tel: (055) 53962-571082 — Telex 570243 OICCONGRE.

Preliminary Program — International Symposium on MONOCLONAL ANTIBODIES '84: BIOLOGICAL AND CLINICAL APPLICATIONS
Florence, October 16-19, 1984

Tuesday, October 16 — 17:00 — 19:00 OPENING CEREMONY

R. Masi (Italy): Presidential Address

A. Falaschi (Italy): New Frontiers of Biotechnology

Wednesday, October 17 MARKERS OF THE IMMUNE SYSTEM

Morning 8:30 — 12:20

Chairmen: G. DORIA and A. BARGELLESI

M. D. SCHARFF (USA): Advances in Monoclonal Antibody Technology

S. L. MORRISON (USA): Ig Gene Expression in Transformed Lymphoid Cells

C. A. BONA (USA): Regulatory Idiotopes

K. RAJEWSKI (FRG): Monoclonal Antibodies in the Analysis of the Idiotypic Network and the Selection of the Antibody Repertoire

J. STROMINGER (USA): Human Histocompability Antigens: Genes and Proteins

12:20 — 14:00 — LUNCH AND POSTERS

Afternoon 14:00 — 18:20

Chairmen: M. RICCI and F. DAMMACCO

L. ADORINI (Italy): Antigen-Specific Monoclonal T Cell Products

R. H. SCHWARTZ (USA): Cellular Co-Recognition of MHC and Antigen

T. TADA (Japan): The Immunoregulatory Molecules Studied with Monoclonal Antibodies

C. GROSSI (Italy): Multiple Marker Analysis of Human Lymphocyte Subpopulations

N. L. WARNER (USA): New Developments in the Definition of Human Leucocyte Subsets by Monoclonal Antibodies

M. F. GREAVES (UK): Human Lymphoid Malignancies

18:20-19:20

Chairmen: G. TRIDENTE and S. ROMAGNANI

POSTER DISCUSSION Thursday, October 18

HORMONAL RECEPTORS AND RELATED AUTOIMMUNE DISORDERS

Morning 8:30 — 12:20 Chairmen: A. PINCHERA and A. ALBERTINI

L. D. KOHN (USA): Thyrotropin Receptor

I. D. GOLDFINE (USA): Insulin Receptor

J. LINDSTROM (USA): Acetylcholine Receptor

G. L. GREENE (USA): Immunochemical Studies of Estrogen Receptor in Normal and Neoplastic Tissues

B. MONCHARMONT (Italy): Application of Monoclonal Antibodies to the Study of the Estrogen Receptor Structure

12:20 — 14:00 — LUNCH AND POSTERS

Afternoon 14:00 — 17:00

Chairmen: M. SERIO and L. MARTINI

CONFERENCES and COURSES

Royal Postgraduate Medical School

(University of London)

Advances in the Applications of Monoclonal Antibodies in Clinical Oncology 6—8 June 1984

This course will cover advances in the understanding of antibody — antigen interactions, and uses in diagnosis and therapy of the new and expanding field of antibody guided localisation of cancer.
The course is suitable for both laboratory scientists and clinicians.

TOPICS INCLUDE:

Heterogeneity of tumours

Blood group antigens on tumours

Differentiation of human germs cells

Growth factors and their receptors on normal and neoplastic cells

Tumour markers

Antibody guided scanning by external body scintigraphy using
a) Radioiodines
b) Other isotopes eg Indium III

Potential uses of antibodies in
a) NMR Imaging
b) Positron emission tomography

Clinical Case Presentations

Ways to improve localisation
a) Use of antibody fragments
b) Use of second antibodies
c) Emission tomography

Therapeutic applications
a) *In vitro*
Bone marrow transplantation
b) *In vivo*
Cytotoxic antibodies
Chemotherapy—antibody conjugates
Radiolabelled antibodies
Antibody-boron complexes for neutron capture
Immunotoxins

SPEAKERS INCLUDE:

Professor K Bagshawe, London, UK,
Professor R W Baldwin, Nottingham, UK,
Dr R Beany, London UK
Dr R Begent, London, UK
Dr W F Bodmer, London, UK
Dr A R Bradwell, Birmingham, UK
Dr K E Britton, London, UK
Dr D Carr, London, UK
Dr D Catovksy, London, UK
Dr K A Chester, London, UK
Dr A A Epenetos, London, UK
Dr R Fairchild, Brookhaven, USA
Dr S Ferrone, New York, USA
Professor D Galton, London, UK
Dr J Goldman, London, UK
Dr P Goodfellow, London, UK
Dr W Gullick, London, UK
Dr J Habeshaw, London, UK
Dr K E Halnan, London, UK
Dr P Lavender, London, UK
Dr E Lennox, Cambridge, UK
Dr J P Mach, Lausanne, Switz.
Dr M Myers, London, UK
Dr M Neville, Sutton, UK
Professor S Orr, London, UK
Professor D K Peters, London, UK
Professor R Steiner, London, UK
Dr P Thorpe, London, UK

COURSE ORGANISERS:
Dr A A EPENETOS, Senior Research Fellow in Clinical Oncology, RPMS, Hammersmith Hospital
Dr K E HALNAN, Director of Radiotherapy and Oncology, RPMS, Hammersmith Hospital

COURSE FEE: **£100 including catering**
Application forms, abstract forms and further details may be obtained from: School Office (SSC), Royal Postgraduate Medical School, Hammersmith Hospital, Du Cane Road, London, W12 0HS. (Telephone: 01-743 2030 ext 351).

Course enquiries:— **Dr A A Epenetos (Telephone: 01-743 2030 ext 353).**

One half day will be open for paper presentations.
Abstracts will be considered for oral and/or poster presentation and, if accepted, will also be considered for publication by the British Journal of Cancer.

CLOSING DATE: 1 April 1984 (1102)C

Industrial Liaison Program of the Massachusetts Institute of Technology presents a short course entitled:

"CONTROLLED RELEASE TECHNOLOGY: POLYMERIC DELIVERY SYSTEMS FOR DRUGS, PESTICIDES, AND FOODS"

Dates: June 4-7, 1984
Chairman: Professor Robert Langer, MIT
Other Speakers: Dr Frank Harris, University of Akron
Dr Jorge Heller, SRI International
Dr Marcus Karel, MIT
Dr Nicholas Peppas, Purdue University
Dr Frank Szoka, University of California

Location: Vienna, Austria

Contact: Maria Clara V. Suva Martin
Industrial Liaison Program
Tel: (617) 253-2691; TELEX: 921473

Attendence Fee: Industrial Liaison Program (ILP) Members — $700.00, Non ILP Members — $900.00.

Topics: Fundamental Principles of Controlled Drug Release; Pharmaceutical Applications; Agricultural Applications; Pesticides; Food Applications; Fabrication Technology of Controlled Release Systems; Liposomes; Microencapsulation; Polymer Technology for Release Systems and Diffusion of Drugs in Polymers.

Abstract:
Controlled release systems improve the ways in which chemical or drugs are administered. Normally, a chemical is administered in a high dose only to have to repeat that dose several hours or days later. This is not economical and sometimes results in damaging side-effects. Thus, increasing attention has been focused on methods of giving drugs continuously for prolonged time periods and in a controlled fashion by incorporating the drugs within polymers.
The program will explore recent advances in controlled release technology and cover polymers systems as they relate to achieving appropriate design of controlled release formulations. (NW260)C

UNIVERSITY OF NOTTINGHAM
MSc COURSE IN MEAT SCIENCE

Applications are invited from GRADUATES in appropriate subjects (normally in Agricultural, Biological, Chemical or Veterinary Sciences) for admission to an advanced course of study leading to the degree of MSc (by examination) in Meat Science. The course, which is of one year's duration, includes Production of Meat Animals, Physiology of Meat Animals, Animal Health & Meat Inspection, Commodity Science of Meat and the Economics and Marketing of Meat. A short dissertation based on research of a topic selected from one of these 5 subjects constitutes part of the overall assessment for the degree.
The course is designed to provide those having appropriate scientific training with specialist knowledge of meat whereby they would be suitably qualified to accept responsibility for the scientific control of ...odity in relation to developments within E.E.C. and in ...

...nts, scholarships may be available.
...the 1984-85 session should write before ...plication form, from the following:
...**Of Agriculture, University of ...hborough Leics LE12 5RD**
(1110)C

KING'S COLLEGE LONDON
MSC in HUMAN AND APPLIED PHYSIOLOGY

A one year course to train graduates in measuring and studying the physiological functioning of man in normal and abnormal environments. The course will equip students to specialise in the applications of physiology to man in industrial, Service and clinical situations and the teaching of human physiology. Topics studied include:— basic measurements; life support systems; exercise; locomotor; postural; climatic; high altitude and hyperbaric physiology.

September 1984 — September 1985

Applicants should normally have a good degree in Physiology or be medically qualified.

Further details and application form from: Dr S Rowlands, King's College London, Strand, London WC2R 2LS, quoting reference N921.

Closing date for applications: March 31 1984. (1121)C

LOUGHBOROUGH UNIVERSITY OF TECHNOLOGY

SEPARATIONS FOR BIOTECHNOLOGY AND BIOCHEMISTRY

SHORT COURSE
26th—30th March 1984

This residential course (forme entitled "Gel Filtration and Electrophoresis") provides thorough and up-to-date coverage of the separation methods used in preparative and analytical biochemistry. Lectures will be supplemented by extensive practical sessions involving the most modern techniques. The course fee including accommodation and all meals, is £275. For reservations and further details contac Miss C D Newton, Departmen of Chemistry, tel: 0509 26317 ext. 351. (1097)C

1984 Cold Spring Harbor Laboratory

Meetings Schedule

Molecular Biology of the Cytoskeleton, April 25-29
Organizers: C. Borisy, *University of Wisconsin*, D. Cleveland & D. Murphy, *Johns Hopkins Medical School*

First International Meeting on Ciliate Molecular Genetics, May 2-6
Organizers: P. Bruns, *Cornell University*, M. Gorovsky, *University of Rochester*

Molecular Biology of the Photosynthetic Apparatus, May 9-13
Organizers: L. Bogorad, *Harvard University*, C. Arntzen, *Michigan State University*, S. Bonitz, *CSH Lab*

RNA Processing, May 16-20
Organizers: H. Robertson, *Rockefeller University*, A. Shatkin, *Roche Institute*, M. Mathews, *CSH Lab*

RNA Tumor Viruses Ninth CSH Meeting, May 22-27
Organizers: T. Hunter, *Salk Institute*, S. Martin, *University of California, Berkeley*

Recombination at the DNA Level, 49th CSH Symposium on Quantitative Biology, May 30-June 6
Organizers: A. Klar & J. Strathern, *CSH Lab*

Molecular Biology of SV40, Polyoma and Adenoviruses, August 15-19
Organizers: T. Grodzicker, *CSH Lab*, M. Botchan, *University of California, Berkeley*

Phage and Bacterial Regulatory Mechanisms, August 21-26
Organizers: S. Adhya, *NIH*, H. Echols, *University of California, Berkeley*

Polypeptide Hormones, August 28-September 1
Organizers: O. Rosen, *Albert Einstein College of Medicine*, R. Ross, *University of Washington*, J. Feramisco, *CSH Lab*

Modern Approach to Vaccines, September 12-16
Organizers: R. Chanock, *NIH*, R.Lerner, *Scripps Clinic*

For information and applications write to:
Meetings Coordinator *or* Course Registrar

Cold Spring Harbor Laboratory
Box 100, Cold Spring Harbor,
New York 11724

Courses in Neurobiology

Neurobiology of Human Disease, June 8-17
Instructors: X. Breakfield, *Yale University*, I. Black, *Cornell University*

Immunoglobulins: Molecular Probes of the Nervous System, June 8-28
Instructors: S. Hockfield, *CSH Lab*, C. Kintner, *Medical Research Council*, L. Swanson, *Salk Institute*, E. Weber, *Stanford University*

Neurobiology of *Drosophila*, July 1-21
Instructors: L. Jan, Y. Jan, & P. O'Farrell, *University of California, San Francisco*, R. Greenspan, *Princeton University*

Molecular Biology of the Nervous System, July 5- 18
Instructors: R. Kelly, *University of California, San Francisco*, R. McKay, *CSH Lab*

Developmental Neurobiology, July 20-August 2
Instructors: D. Purves, *Washington University*, P. Patterson, *California Institute of Technology*

Advanced Electrophysiological Methods, July 24-August 13
Instructors: P. Ascher, *Ecole Normale Supérieure*, S. Schuetze & S. Siegelbaum, *Columbia University*

Courses in Genetics

Molecular Biology of Plants, June 8-28
Instructors: I. Sussex, *Yale University*, R. Malmberg, *CSH Lab*, J. Messing, *University of Minnesota*

Molecular Cloning of Eukaryotic Genes, June 8-28
Instructors: A. Bothwell, *Yale University*, F. Alt, *Columbia University*, J. Mullins, *Harvard School of Public Health*

Advanced Bacterial Genetics, July 1-21
Instructors: T. Silhavy & M. Berman, *Frederick Cancer Research Facility*, L. Enquist, *Molecular Genetics, Inc.*, S. Bear, *NIH*

Molecular Embryology of the Mouse, July 8-21
Instructors: B. Hogan, *Imperial Cancer Research Fund*, F. Costantini, *Columbia University*, L. Lacy, *Sloan-Kettering Cancer Center*

Advanced Techniques in Molecular Cloning, July 24-August 13
Instructors: T. Atkinson & M. Smith, *University of British Columbia*, J. Fiddes, *California Biotechnology, Inc.*, D. Shortle, *State University of New York, Stony Brook*

Yeast Genetics, July 24-August 13
Instructors: F. Sherman, *University of Rochester*, G. Fink, *Massachusetts Institute of Technology*, J. Hicks, *CSH Lab*

(NW261)C

STUDENTSHIPS

UNIVERSITY OF EAST ANGLIA
NORWICH

POSTGRADUATE STUDENTSHIPS
SCHOOL OF BIOLOGICAL SCIENCES

Applications are invited for SERC Studentships from candidates with interests in any of the following areas: —

Biophysics, Biochemistry, Ecology, Genetics, Microbiology, Plant Biology, Physiology, Zoology

Candidates should have, or expect to obtain in 1984, a First or good Upper Second Class degree. It is expected that at least five Studentships will be available. Applicants should write to the Director of Graduate Studies (C), School of Biological Sciences, University of East Anglia, Norwich NR4 7TJ, enclosing the names of two academic referees. Details of the research interests of members of faculty are available on request. (1112)F

SOUTH MANCHESTER HEALTH AUTHORITY

CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE

STUDENTSHIPS FOR TRAINING IN RESEARCH

Five Cancer Research Campaign financed studentships will be awarded in these multidisciplinary laboratories for full time studies leading to higher degrees in research fields relevant to cancer. Successful applicants will work in one of the following divisions; biophysical chemistry, radiobiology, experimental chemotherapy, carcinogenesis, cell biology, experiment haematology, cell and tissue kinetics, ultrastructure, immunology and molecular biology.

Awards will be tenable for three years from 1 October 1984, with a tax-free grant of £2,880. Applications are invited from candidates who have or expect to obtain a first or upper second class honours degree.

Applications, which should include a detailed curriculum vitae and the names of three academic referees, should be sent to the Director, The Paterson Laboratories, Christie Hospital and Holt Radium Institue, Wilmslow Road, Withington, Manchester M20 9BX (Tel. 061-445 8123 ext 400) as soon as possible and in any case not later than 1 March 1984. (1087)F

GRANTS and SCHOLARSHIPS

GUNNAR NILSSON CANCER RESEARCH TRUST FUND

Grant applications up to £15,000 sterling will be considered to assist cancer research projects where money is not available from the normal grant giving bodies. An application form is available, and applications should be received by 30 June 1984.

Applications to be sent to Dr Norman Howard, Chairman, Gunnar Nilsson Cancer Research Trust Fund, Department of Radiotherapy and Oncology, Charing Cross Hospital, Fulham Palace Road, London W6 8RF. (1096)H

THE ROYAL SOCIETY GOVERNMENT GRANT FOR SCIENTIFIC INVESTIGATIONS

Applications for grants from the first allotment of the Government Grant for Scientific Investigations for the year 1984 (for which the amount available will be substantially less than in recent years) should be made not later than 15 March 1984 on forms of application to be obtained from the Executive Secretary of the Royal Society, 6 Carlton House Terrace, London SW1Y 5AG.

Applicants must be British subjects domiciled in the United Kingdom. Grants may be made to promote and support research in science and to assist scientific expeditions and for personal stipends or [illegible]ions.

ASSISTANTSHIPS

AFRC UNIT OF NITROGEN FIXATION

RESEARCH ASSISTANTSHIP

Applications are invited for a 3 year research assistantship in the Unit of Nitrogen Fixation, leading to a D.Phil. degree at the University of Sussex. The project is under the supervision of Drs J R Dilworth and B E Smith and will involve chemical and spectroscopic studies of the iron-molybdenum co-factor of nitrogenase and the synthesis of relevant iron and molybdenum sulphur complexes.

Applicants should hold or be likely to hold a 2.1 (minimum) honours degree in Biochemistry or Chemistry and should send a curriculum vitae to the Secretary, AFRC Unit of Nitrogen Fixation, University of Sussex, Brighton, BN1 9RQ. (1122)P

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
DEPARTMENT OF BIOCHEMISTRY

POST DOCTORAL RESEARCH ASSISTANTSHIP

Available immediately for approximately two years to work on "Control of Testis Leydig Cells by Intra- and Extra-Testicular Factors". Appointment supported by a grant to Professor B A Cooke from the Wellcome Trust. Candidates should have experience in one or more of the following:- Cell purification and culture, radioimmunoassay, receptor assays and steroid biochemistry.

Full curriculum vitae, including the names and addresses of two referees, should be submitted by 17 February 1984 to the School Office, RFHSM, Rowland Hill Street, London NW3 2PF (telephone 01-794 0500 ext 4262) from where further particulars are available. Please quote reference BAC/RA. (1139)P

LADY TATA MEMORIAL TRUST
INTERNATIONAL AWARDS FOR RESEARCH ON LEUKAEMIA AND ALLIED CONDITIONS

ACADEMIC YEAR 1984 — 198

The Trustees of the Lady Ta Memorial Trust invited applicatio for Awards for personal support f research on leukaemia, in th Academic Year beginning 1 October, 1984. In view of the affini between leukaemia and other form of neoplastic disease, candidate with programmes of research on an aspect of malignant disease whic may throw light on problems leukaemia will be eligible f consideration. The Trustee specially wish to encourage studie of the leukaemogenic viruses animals, the epidemiology pathogenesis, and immunology leukaemia.

Awards are open to suitab qualified investigators of a nationality, working either in th own institutions or in other cent abroad.

Stipends will be adjusted accordi to the place and institution at whi the work will be done, with provisio for annual increments an superannuation if required. Awar in recent years have usually bee between £5,000 and £10,000.

Awards are tenable for 1 year in t first instance, renewable up to maximum of 3 years.

Further particulars and applicatio forms may be obtained by writing the Secretary of the (Europea Scientific Advisory Committe Lady Tata Memorial Trust, MR Leukaemia Unit, Royal Pos graduate Medical School, DuCa Road, London W12 0H Applications must be submitt before 1st March, 1984 and awar will be announced by the Trustees June. (1131)N

ASSOCIATESHIPS

THE UNIVERSITY OF SYDNEY RESEARCH ASSOCIATESHIP — PLASMA PHYSICS

Applications are invited for Research Associateship in plas physics. The appointment would for two years from a date in period July-December 1984. T appointee would collaborate in theoretical aspects of t Department's Alfven wave heat program.

Salary range: $A20,164 $A22,513 pa.

Further information can obtained from Professor M Brennan, Wills Plasma Phys Department.

Applications close with Registrar, University of Sydn NSW 2006, Australia, on 31 ma 1984.

Equal employment opportunity University policy. (W728)C

AWARDS

The Wellcome Trust

Major Award for Psychological Research into Mental Disorders

The Wellcome Trustees invite proposals from suitable departments in the United Kingdom for an award totalling £250,000 over five years, for the pursuit of experimental and development psychological research into the genesis of mental disorders.

Please write for an application form to: The Grants Section, The Wellcome Trust, 1 Park Square West, London NW1 4LJ.

Completed applications must be returned not later than 6th April 1984.

The living proof

The 1,000 delegates to Biotech '83 were proof positive that the business of biotechnology is booming. There is tremendous enthusiasm and need to know.

Biotech '84 Europe builds on that success to present a totally fresh forum. The solid information you want and need to know will be presented by key figures in the fast-growing fields of biotechnology and their commercial applications.

Topics featured strongly in the programme include *Novel Tools and Technologies* such as protein modelling using computer graphics and site-directed mutagenesis, new approaches in *Healthcare and Diagnostics, Agricultural Biotechnology* and the vital, but frequently neglected intricacies of *Regulations* and *Finance*.

The informal programme includes a Government-hosted reception at the Banqueting House in Whitehall, visits to the concurrent Biotech '84 exhibition and, naturally, the opportunity to glean news from colleagues from every corner of world biotechnology.

...Quality

Actually, the Pharmacia P-L Biochemicals Product Reference Guide lists over 2000 products for biochemistry and molecular biology. The products range from restriction nucleases to coenzymes, from lipids to polynucleotides – but our most important product is the quality that goes into each biochemical that we make.

At Pharmacia P-L Biochemicals, we take our commitment to "excellence in biochemistry" seriously. We make our biochemicals with quality – we know no other way.

The 1984 Product Reference Guide from Pharmacia P-L Biochemicals

Quality biochemicals for quality research.

Why researchers pay a little more for our acrylamide.

They have discovered the unsurpassed performance of Bio-Rad acrylamide:

- Reproducible separations. Even small impurities can make a big difference in results!
- Higher resolution from techniques such as Laemmli SDS-PAGE, 2-D electrophoresis, and electrofocusing.
- Gels that polymerize reproducibly and quantitatively.
- Separations free of artifacts which interfere with clear interpretation of results.
- High purity also means longer shelf life.

If your bottle says "store at 4°C," it's not pure. Bio-Rad acrylamide can be stored dry at ambient temperatures for long periods.

The acknowledged quality of our acrylamide is typical of all Bio-Rad electrophoresis chemicals, including glycine, Bis, Tris and SDS.

Furthermore, Bio-Rad supports you with a wealth of technical data, applications assistance, and tips on proper technique. That alone is worth the price.

Contact us for our latest Technical Bulletin on step-by-step polymerization protocols.

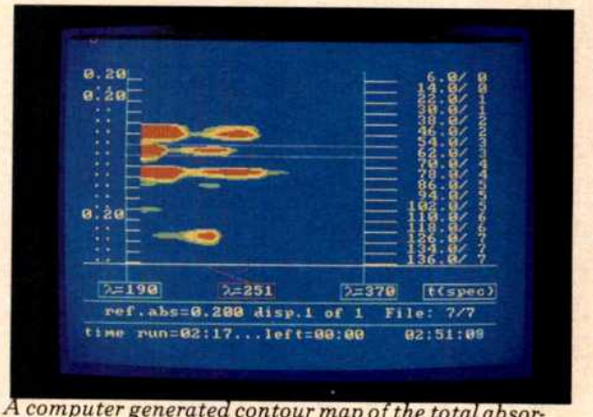
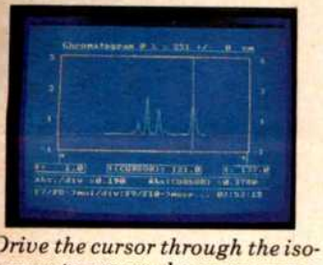
YOU JUST CAN

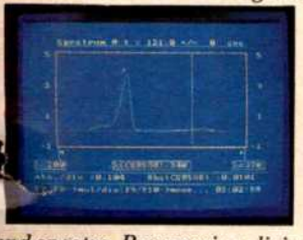


WITH LKB's NEW DI

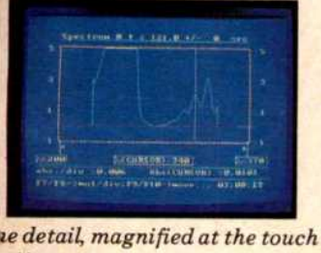


T MISS PEAKS

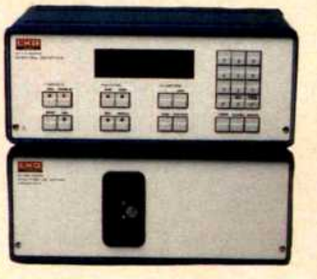
E ARRAY DETECTOR



ush-button access to chromatograms and spectra, combined with an innovative icing technique, automatically surveys and explores the whole chromatographic ndscape. Equips you with colour-graphic ed back for an analytical follow-through no her system offers. Power to track, expose id pinpoint all your peaks. Only LKB's Rapid pectral Detector lets you rapidly pursue, sily discover and clearly reveal every single eak—and then deliver it blown-up in perfect detail. So however small, or wherever it's hidden, you'll just never miss a peak—you just can't! The Rapid Spectral Detector is a computer based diode array detection system that offers dramatic breakthroughs in HPLC. With real time display and raw data storage Rapid Spectral provides the true visual command you need for complete analytical insight. Lets you probe new perspectives to give you more information and better results. So if you want to find those missing peaks, get in touch with LKB. We'll send you a broschure that describes the very best in diode array technology. You'll find it infinitely revealing, just like our Rapid Spectral Detector.



A computer generated contour map of the total absorbance pattern after separation. The vertical and horizontal axes are time and wavelength respectively. Colour coding is used to represent different levels of absorbance for each isogram.



Drive the cursor through the isograms to access chromatograms...

and spectra. Progressive slicing rapidly reveals every peak, hidden or not.

ue detail, magnified at the touch of utton.

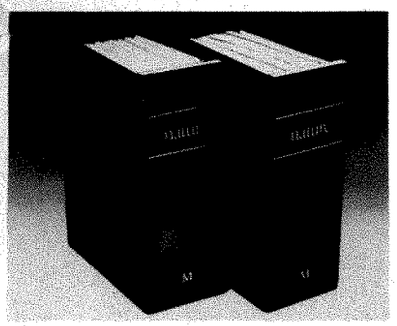
SKATRON MICROFRACTION COLLECTOR

The Skatron microfraction collector was designed to be used with 96 well microplates or macrowells in microplate pattern and very short tube change. This gives also the following features:

- Fractions are automatically numbered
- Easy handling and storage in minimal space
- Improved economy
- Direct measurements by ELISA or RIA
- No sample loss
- Collection of equal sized fractions

SKATRON MICROWASH 96 WELL AUTOMATIC MICROPLATE WASHERS



2 models of 96 well washers available. The Microwash will wash both rigid and flexible microplates.
An off centre inlet tube combines turbulence with dilution to maximize washing efficiency, a semi-beveled outlet tube permits thorough aspiration regardless of well shape, and an overflow prevents crosscontamination of wells by wash fluid.

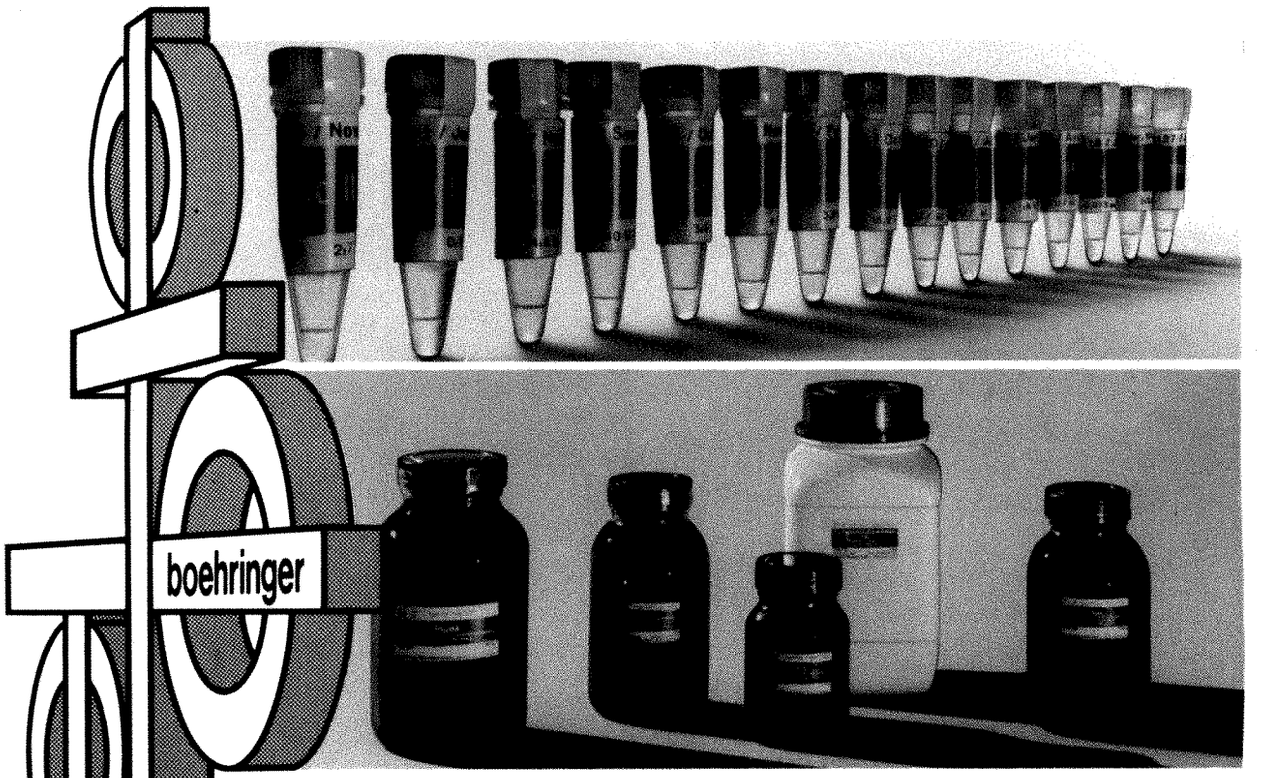
GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.



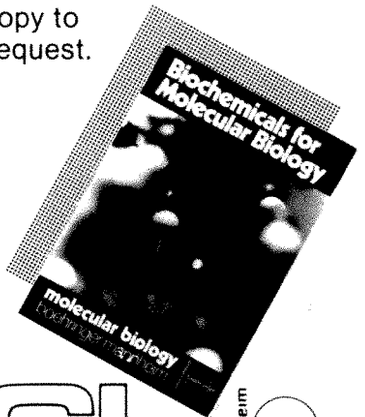
Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*



Boehringer Mannheim are extending their range of restriction enzymes and buffers

Aha III, Sau I (MstII) and Stu I are part of the rapidly expanding programme of restriction enzymes from Boehringer Mannheim. Not only is our range *wider* than ever, but each new enzyme is supplied with a comprehensive batch-specific data sheet for optimal control of experimental conditions.

Boehringer Mannheim's range of buffers is expanding too. Each one undergoes the highest standard of purification and quality control to provide you with a reliable yet economical preparation. *Tris*, for example, is notable for its low level of heavy metal contamination, whilst *Hepes* is suitable as a cell culture buffer since it is function tested for cell growth.

A new book *"Biochemicals for Molecular Biology"* presents information on our range of products for the Molecular Biologist. We will send a copy to you on request.

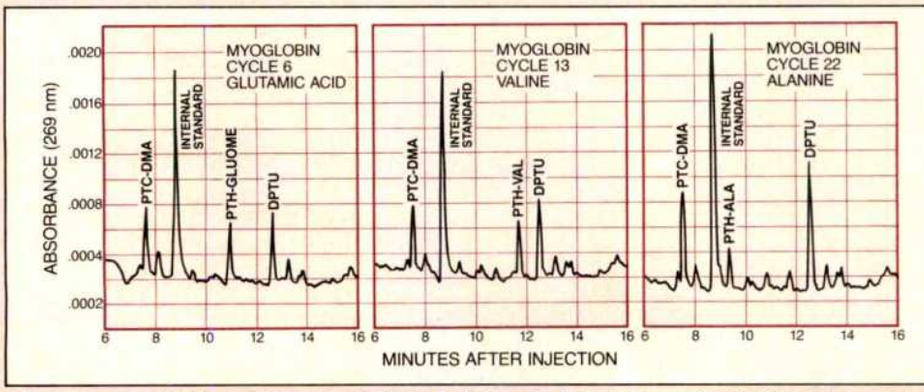
BIOSYSTEMS UPDATE

Gas-Phase Protein Sequencing

A Progress Report

Less than two years ago, Applied Biosystems introduced new gas-phase protein sequencing technology which, though in its infancy, set new standards of analytical performance and sensitivity. We are now pleased to announce the first in a series of improvements in chemistry, programming and hardware which begin to further realize the still untapped potential of the Model 470A Gas-Phase Protein Sequencer.

Changes in the coupling, cleavage and solvent extraction times, and use of an optional miniature sample cartridge, substantially increase repetitive yields and decrease lag on picomole level samples. Sequencer artifacts which can interfere with high sensitivity PTH-AA chromatography are also reduced by a factor of three to five.



34 residues of 20 picomoles of sperm whale apomyoglobin. Repetitive yield is 96% calculated from the least squares linear regression plot of individual amino acids quantitatively recovered at each sequenced cycle. Lag averages less than 1%/cycle.

The improvements are particularly dramatic with peptides. A user evaluating our new chemistry has reported sequencing the octapeptide angiotensin II to completion with only 25 picomoles of sample.

A new miniature PTH conversion flask increases typical PTH-AA recovery to greater than 95%. The improvement is most significant on serine, threonine and tryptophan since drying times are reduced threefold.

Best of all, these improvements, and others still under development, are designed to be compatible with every instrument we've built so our current users will continue to be at the leading edge of protein sequencing technology. The 470A Gas-Phase Protein Sequencer is capable of setting even higher performance standards and Applied Biosystems, in collaboration with many of our users, is continuing to investigate further improvements to this remarkable instrument. If you'd like more information, please circle number 8.

Actual HPLC chromatograms, without background subtraction or data enhancement, of residues 6, 13 and 22 from sequencing analysis of 20 picomoles of sperm whale apomyoglobin. The data illustrate the low background and high sensitivity of the Model 470A Gas-Phase Protein Sequencer.*

**Chromatography: IBM Cyano Column. Internal Standard: MTH tyrosine. PTH yields normalized to 100% injection: Cycle 6 (glutamic acid)—11.7 pmol, cycle 13 (valine)—9.1 pmol, cycle 22 (alanine) 6.2 pmol. PTC-DMA, phenylthiocarbamyldimethylamine; DPTU, diphenylthiourea.*

Eupergit®

the carrier for advanced biotechnology

Eupergit®

Research & Development
Industrial large scale processing

the carrier for a wide range of application in bioengineering:

- covalent immobilization
- bio-catalysis
- all other bio-affinity techniques

Advantages

- high quality and quantity product yield
- excellent stability of matrix and bonded ligands
- suitable for most reactors
- easy to handle
- ecologically safe
- non-toxic

Go with Eupergit into production of biopharmaceuticals, e.g.:

- 6-amino-penicillanic acid
- amino acids for parenteral infusions
- optically pure substances

Pharmaceutical grade:

- deoxy nucleotides and nucleosides
- enzymes, enzyme inhibitors, hormones, blood proteins, immuno globulins, antibodies and their fragments
- immune modulators, such as interferons or interleukins

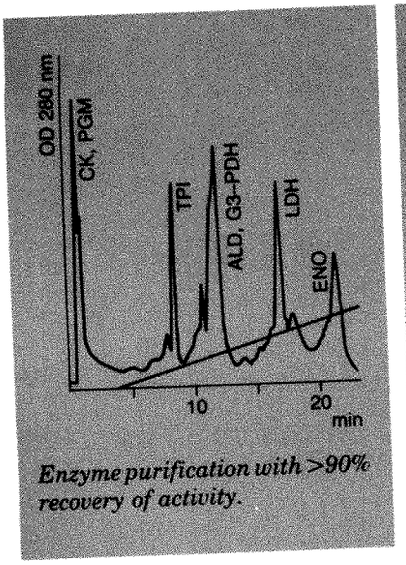
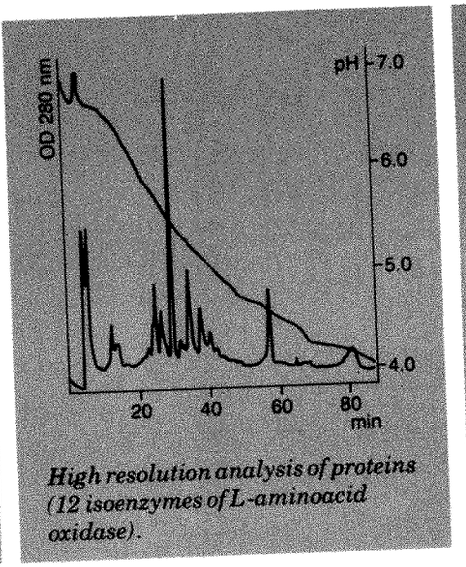
FPLC means ...

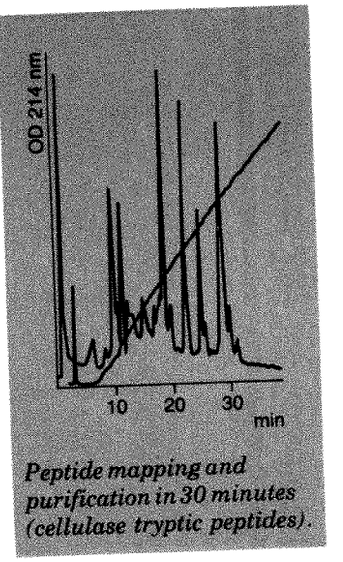


Separation power



Fast Protein/Peptide/Polynucleotide Liquid Chromatography – but speed is not its only virtue.

FPLC means new unique, hydrophilic, monodisperse media providing high performance resolution and high recovery of biological activity: and new silica based media providing high performance resolution, superior yields of proteins, peptides and polynucleotides – with sample sizes up to 100 mg.

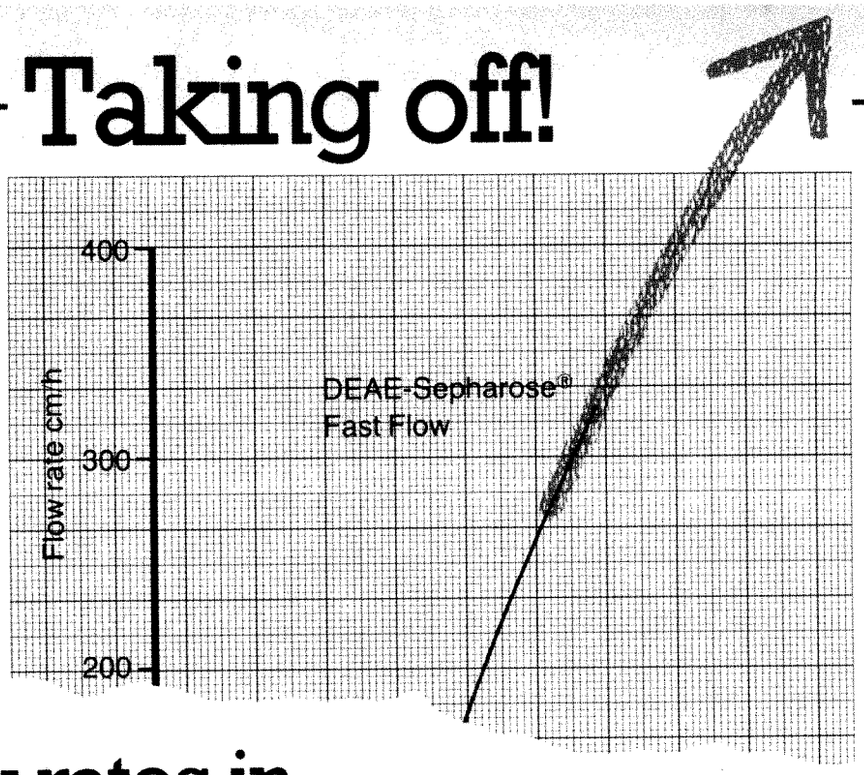


FPLC means new instruments, new media and methods – the combination of which is a high performance liquid chromatography system providing a degree of resolution, capacity and speed previously unattainable for purifying proteins, peptides and polynucleotides.

Enzyme purification with >90% recovery of activity.

High resolution analysis of proteins (12 isoenzymes of L-aminoacid oxidase).

Peptide mapping and purification in 30 minutes (cellulase tryptic peptides).



For further information about the separation power of the FPLC System, please contact your local representative of Pharmacia Fine Chemicals.

Taking off!

Flow rates in large scale chromatography

The flow rates that you can get in laboratory, pilot and production scale ion exchange chromatography are taking off.

The reasons?

- *DEAE-Sepharose Fast Flow*
- *CM-Sepharose Fast Flow*

The results?

- *Faster processing and greater through-put*
- *Easier scale up and simpler operation*
- *Switch from batch to column techniques*

Both of these Fast Flow ion exchangers are new. They're based on the widely-used and well-documented DEAE- and CM-Sepharose CL-6B gels. Optimization of the cross-linking now allows you to use high flow rates at all scales of operation – up to 180 cm/h at pilot and production levels and much much more at the laboratory bench. This means well over 10 bed volumes per hour or up to 15 l/min in Sephamatic® GF 08-015 seventy five litre production columns under normal operating conditions.

Even in difficult processing situations, Fast Flow gels make life easier for you. For example, 500 litres of bacterial cell extract containing a biosynthetic product maintained at 4°C – and that means a fairly viscous solution – can be run through a 16 litre KS 370 Stack column containing DEAE-Sepharose Fast Flow in about 5 hours. (Data from KabiVitrum AB, Stockholm). And if you're currently operating batch ion exchange processes, these gels will probably allow you to change to more convenient and reproducible column techniques.

Scaling up processes becomes easier as well, now that you can use high flow rates all the way from the laboratory, through pilot plant and into production.

Some things haven't changed though. The first class chemical and physical stabilities of the CL-6B gels have been kept. You can re-equilibrate and wash *in situ* and you don't have to worry about fines breaking off and blocking the column. And when the new and old gels were assessed by independent producers in Europe and the United States, they found no differences in the characteristics of the purified products.

Act fast yourself. Order from your usual representative of Pharmacia Fine Chemicals ...

	500 ml	10 litre
DEAE-Sepharose Fast Flow	17-0709-01	17-0709-05
CM-Sepharose Fast Flow	17-0719-01	17-0719-05

... or request further information today.

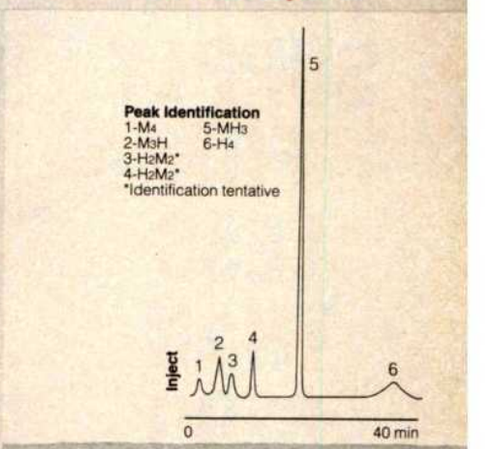
Now isolate and analyze proteins faster, with higher resolution and recovery.

Waters HPLC systems with new ion exchange, gel filtration and hydrophobic packings for biological separations.



High speed gel filtration separation of insulin.

Total recovery of enzymatic activity from a crude bacterial extract using ion exchange.

High resolution ion exchange separation of isoenzymes.

Separation time: 12 minutes.

Waters new high speed gel ation methods allow rapid tionation of protein samples. s same gel filtration method lets profile sample composition, ate all components and verify purity of collected fractions.

ple: 10 µl Insulin, 5 mg/ml
mn: PROTEIN-PAK 125
nt: 0.1% Trifluoroacetic Acid, pH 2.1
Rate: 1.0 ml/min
ction: 214 nm, 0.5 AUFS

100% recovery of biologically active protein.

The large pore size of Waters polymeric ion exchange packings (1,000 Å) gives you recoveries of enzymatic activity approaching 100% for even high molecular weight enzymes.

Sample: 100 µl Bacterial Extract, 3 mg/ml
Activity: Glucose-6-Phosphate Dehydrogenase
Column: PROTEIN-PAK DEAE 5PW
Gradient Conditions
Eluent A: 0.02M Tris HCl, pH 8.5
Eluent B: 0.02M Tris HCl, pH 8.5 + 0.5M NaCl
0-100% B, curve 6, 25 min
Flow Rate: 0.5 ml/min
Detection: 280 nm, 0.1 AUFS
Specific Activity Increase: 4.9
Activity Recovery: 100%

Complete resolution of LDH isoenzymes.

The resolving power of Waters high performance ion exchange packings provides resolution of the closely related isoenzymes of lactate dehydrogenase.

Sample: 100 µl LDH Isoenzymes, 1 mg/ml
Column: PROTEIN-PAK DEAE 5PW
Gradient Conditions
Eluent A: 0.02M Tris Acetate, pH 8.0
Eluent B: 0.02M Tris Acetate, pH 8.0
+ 1.0M NaOAc
0-100% B, curve 6, 45 min
Flow Rate: 0.5 ml/min
Detection: 280 nm, 0.05 AUFS

Add the performance of Waters HPLC to your separations. And achieve greater success in protein isolation and analysis.

For a demonstration or additional information, contact your local Waters representative or call 617-478-2000 (X 2665).

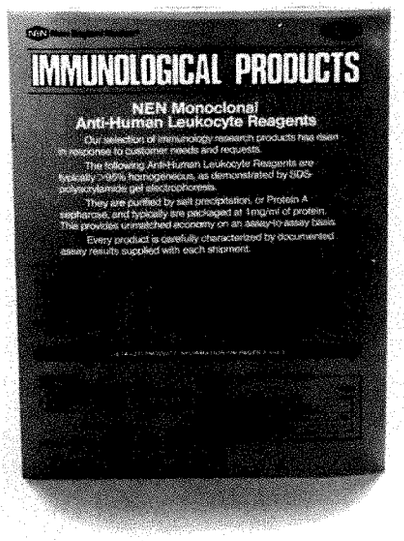
Monoclonal Anti-Human Leukocyte Reagents

Are you differentiating cell types—myeloid, CALLA, lymphoid (B- or T-cell subsets)? If so, consider our new and thoroughly characterized reagents for building your panels.



Our monoclonal anti-human leukocyte reagents are >95 percent homogeneous, as demonstrated by SDS-polyacrylamide gel electrophoresis. They are purified by salt precipitation, or on protein A sepharose, and are packaged at a protein concentration of 1 mg/ml. This provides unmatched economy on an assay-to-assay basis.

Equally important, every reagent is carefully characterized by lot-specific assay results supplied with each shipment.

Don't be without our catalog of reagents for immunological studies. In it you will find anti-human leukocyte reagents, as well as:

- Monoclonal antibodies specific for mouse immunoglobulin studies
- Allele-specific monoclonal anti-mouse lymphocyte reagents
- Enzymes and fluorescent-labeled conjugates of both monoclonal and polyclonal antibodies
- Hybridoma screening systems for murine immunoglobulins

Simply circle the inquiry number to receive the catalog without charge. We'll also keep you informed of future products as they're developed.

Reagan votes for basic research

The budget deals generously with basic science; the snags are that the election will tempt Congress to deny the President what he wants and that the strategy of budget deficits may blow up in his face.

PRESIDENT Ronald Reagan's pre-election budget is what his pollsters had been expecting and will not surprise even his would-be opponents next November. Between now and then, politicians and voters alike will be less concerned with what is called the bottom line — the huge deficit yet again in prospect — than with the details of spending plans for the financial year that will have just begun by election day. In the circumstances, it is commendable that the new budget is less like an electioneering document than it might have been. Moreover, other things being equal as the economists say, the budget could do much to strengthen basic research in the United States. So the important question is whether Congress will let good things come about. And while there is no reason to suspect that Congress has its knife into basic science, the danger is high that in the run-up to the election, large chunks of the budget will be so encumbered with spending plans the administration cannot accept that the business of the United States will be managed by continuing resolutions until after the votes have been counted. Those planning to order new equipment on the strength of last week's budget will prudently contain themselves in patience.

Of all the components of the budget, the most welcome because the most overdue is the proposal that federal support for agricultural research should be put on a more rational basis. The plan is that, from next October, the US Department of Agriculture should have $50 million to spend on research grants awarded competitively, twice as much again as in the year now under way. This shift of resources, in magnitude only modest, will be significant if it can be taken as a commitment by the administration to the principle that agricultural research in the United States should be reformed.

Opposition

Handing out large parcels of public money to the land-grant colleges was a powerful stimulus to self-conscious agriculture at the end of the nineteenth century, while the Department of Agriculture's own research establishments were fruitful sources of basic science as recently as half a century ago. But times have changed. It is now comically anomalous that agriculture, the most important single industry in the United States, should uniquely be deprived of more than token access to the groups of imaginative people in US universities willing and able to break a lance or two in the interests of the agriculture of the future — and without demanding a public service contract and pension in return. None of this is to pretend that competition for research grants, and the peer reviews that attend them, are free from blemish or to deny the value of what industrial companies are now spending — perhaps $100 million a year — on basic research in agriculture. But it will be a test of the administration's seriousness towards research that it should be prepared to battle for the modest proposal now put forward in the face of the entrenched opposition there will be in Congress.

The next most welcome development is the proposed generosity towards the National Science Foundation, still no better endowed in real terms than in the early 1970s. Again it makes sense that the only agency of government able to support projects not tied to what are called missions (public health included) should have more funds at its disposal when executive agencies and private industry are both busily spending more in the universities, helping to shape the pattern of research in the image that suits them best. Because the foundation's spending bears more directly on the quality of technical education, in secondary schools as well as in universities, the promised increase cannot fail to be a sound investment. The fact that they may materialize is a feather in the cap of Dr George ("Jay") Keyworth, director of the Office of Science and Technology Policy at the White House. So too is the decision not to leave to Congress the choice of a number to represent the budget of the National Institutes of Health, for there will now be less scope for the dreaded Waxmans to monkey with the constitution of the institutes.

Disappointments

For the rest, where research support is concerned, the new budget is the predicted mixture of small disappointments. The National Aeronautics and Space Administration will continue to gather information about the Solar System more quickly than it can afford to have the data analysed and digested. There will, indeed, be $150 million to be spent next year on the early design of a space station whose purpose has not yet been decided. There seems to be nothing in the budget to offset the decline of modest overseas collaboration threatened by the proposed withdrawal from the United Nations Educational, Scientific and Cultural Organization (Unesco). Star wars, or preparations for them, are to flourish. The fast breeder reactor has finally been abandoned but for the wrong reason; the Department of Energy should have recognized years ago that the Clinich River design is technically obsolete, but should this year have made provision for the "crash programme" of fast reactor development for which Congress will be crying when it gets to hear of the European plan for cooperation in this field.

These complaints are only minor minuses compared with the outstanding weakness of the federal budget for 1985 — the administration's plan to finance its operations during the coming year by the device on which it has relied since it came to office, the trick of paying its bills with borrowed money. The sums involved are vast, in round numbers $200 million a year or two-thirds of the enlarged defence budget that Congress is being asked to approve. The federal government's borrowing amounts to 6 per cent of the gross national product of the United States, which is another way of saying that the government used the whole of last year's growth to cover the gap between what it spent and what it raised in taxes. The debt that has accumulated after nearly a decade of this spendthrift way of running a government has risen so that annual interest payments now exceed 2 per cent of the gross national product, and are reaching the point at which no Secretary of the Treasury can hope to escape from them. The borrowed funds come from two sources, domestic savers (including corporations) in the United States who lend to the government funds that would otherwise be invested in productive industry, and investors overseas who find it profitable to put money into US financial securities while interest rates remain high and who have so far also thought it safe. As the months go by, they increasingly ask themselves whether it is wise to have lent so much on the chance that the federal government will one day be in balance again.

The symptoms of this imbalance are plain, at least from the outside. Because interest rates must be kept high to attract borrowers, the dollar is strong compared with other currencies, US

© 1984 Macmillan Journals Ltd

manufacturers are less able to sell their products on world markets and the United States must run a huge deficit on its trade balance — $40,000 million last year, probably more in 1984. Even though the flexibility of the US economy has in the past year allowed for growth (by no less than 6 per cent) without accelerating inflation, even President Reagan agrees that this state of affairs cannot continue much longer. His offer last week to negotiate with Congress some way of moving towards a balance (by 1989) is unlikely to bear fruit in the run-up to the election. The question that will increasingly keep people awake at night is whether before then the house of cards will collapse, perhaps because overseas investors in the United States take fright, perhaps because still higher interest rates bring the economic recovery to a stop.

On the face of things, these arcane considerations may seem to have no bearing on the provisions in last week's budget for the support of basic science. But they are crucial. In due course, the federal government will have to balance its books more closely by increasing taxes or by spending less. Either way, the flickering economic revival will be impeded. If spending cuts are the chosen method, who can be sure that the generosity of this year's budget towards basic science can be maintained? If higher taxes bear the brunt, who can be sure that the funds now channelled from industry towards basic science will continue to flow. And if the administration, this or the next, chooses to fudge the issue by allowing inflation to run riot again, who will be safe? □

Time to move Greenwich

On the centenary of the choice of the zero of longitude, other places for it deserve a hearing.

IN the week in which Britain, once an imperial power on whose vast possessions, it was said, the Sun never set, has suffered the humiliation of being thoroughly beaten by upstart New Zealand at the national sport of cricket (like baseball, played with pieces of wood and bruising balls, but unlike baseball in that games can last for five days), it is natural that there should have been nostalgic celebration of the centenary of the choice of the meridian through Greenwich as the commonly agreed zero of longitude. Here at least, wishful argument seems to go, is proof that there was a time when the centrality of the British place in the world was generally acknowledged. But even that may be a slightly hollow comfort.

The truth is that Greenwich is far from being the most convenient place through which to trace the zero of longitude. In Western Europe, one of the most densely populated regions of the world, several countries (Britain, France, Spain and so on) find themselves straddling the meridian, unable to decide whether they belong to the Eastern or the Western Hemisphere. Plainly a better choice would have been to place the zero of longitude 10 or even 20 degrees west of where it is at present; the first choice would have left only New Zealand uncertain where it is, the second would have bisected the surface of the Earth in such a way that no country of importance was thus embarrassed. Astronomers, after all, are usually reasonably clever people, and would have been able to assimilate the notion that the zero of longitude should be in the mid-Atlantic just as astronomers in Potsdam and Pulkova have had to learn that they have been well to the east of it.

It is also important, at this centenary, modestly to acknowledge that the conference in Washington in 1884 that settled on Greenwich (with one dissenting vote) let slip a splendid opportunity to put on a more reasonable footing the measurement of angular displacement. The sad truth is that, from sheer indolence and inertia, generation after generation of people who acknowledge the good sense of measuring most quantities on a decimal scale have indolently allowed themselves to continue measuring angles in an arithmetic whose radix, for practical purposes, is 60. By doing so, they have lazily adopted a system variously attributed to the Babylonians and to the ancient cultures of India. It is true, of course, that changing to a system in which, say, radians would be the equivalent of 100 degrees would have been a considerable undertaking, and that it would have been necessary also to decimalize time. But that is no excuse for having done nothing. □

How not to test drugs

British and French anxiety about human volunteers in drug trials should be settled quickly.

THE British pharmaceutical industry, long used to the cultivation of an air of injured innocence in the face of complaints from central government about the prices of drugs sold to the public health services and from sections of the general public that its products are unsafe, has every reason to be aggrieved that some of its arrangements for testing a new drug in volunteers should have called in question the whole basis on which the toxicity of new compounds is assessed (see page 495). The only immediate comfort is that a similar issue has, by coincidence, arisen in France.

The circumstances in which this row has arisen are not nearly as complicated as they seem. In Britain as elsewhere, clinical trials to assess the efficacy and side effects in patients of a potential drug require formal approval from the regulatory body, the Department of Health acting on the advice of the Committee on the Safety of Medicines. But manufacturers, required by established procedures to provide evidence of the toxicity of a new drug by means of tests with animals, also have an incentive to provide evidence that the new material causes no obvious harm to people. The tradition that a person responsible for developing a new material will try it out on himself and his close colleagues (never satisfactory) has in the past few years become outdated as the need has grown for more and more systematic tests in human beings as part of the process of licensing a drug for clinical trials. The result is the practice of delegating testing in volunteers to commercial companies.

Except to those who hold or seem to hold that new medicines as such are an abomination, there is nothing wrong with these procedures, at least when they are followed sensibly. What has gone wrong with the study of a putative tumour inhibitor is that the good sense of the proposal has not been assessed by people at once knowledgeable enough to make an informed judgement, independent in the sense that no benefit accrues to them and publicly identifiable. A commercial company's internal ethical committee whose identity is not disclosed will not suffice when volunteers are recruited publicly, and invites complaints that participants have been less than fully informed of the risks they run. The failure of the company concerned to inform the volunteers' own physicians of what was afoot is another needless omission. But it is sheer humbug that many who should know better have been complaining that by offering participants a cash reward of £250, those mounting the study have been offering inducements great enough to sway a person's judgement of his own long-term interests. It could just as well be argued that a participant without the wit to demand a fee of this order is unlikely to be fit to give informed consent.

The danger now is that the Department of Health will panic at what appears a little like the discovery of a loophole in the arrangements for the regulation of drug testing, introducing another layer of paperwork with which to belabour the drug industry and, worse still, to impede the development of new medicines. The need, however, is far simpler — a publicly agreed set of guidelines by which all drug testers can be bound. The rules should be easily devised. The socially disadvantaged, especially prisoners and old people, should not be allowed to volunteer for drug tests unless, as the French ministry of health suggests, there is reason to think their health may benefit. People who are not sufficiently alert to give informed consent should similarly be excluded. Consent for all drug studies should be given by properly constituted ethics committees, whose names and credentials are known and whose opinions will be made publicly available. Nobody should complain if people or even university departments occasionally make modest sums of money out of these procedures. Now and again, ministers of health should summon up their courage and make public speeches pointing out the need for such activities, now too easily and too often counted as dispensable. □

US budget

Military and basic science offered more rapid growth

Washington

PRESIDENT Reagan released his proposal for the 1985 federal budget last week, and left no doubts about the direction of his research and development policy: massive increases on the military side. The President proposed a record $33,852 million for military research and development, an increase of 22 per cent over current spending. And while total civilian research and development spending would be held almost constant under the President's plan, its basic research components would increase by 10 per cent overall, with particularly generous treatment for the National Science Foundation (NSF), the National Aeronautics and Space Administration (NASA) and the Department of Energy.

The new money for basic research is to come largely from deep cuts in applied research and — that particular bugaboo of the Reagan Administration's free-market philosophy — the engineering demonstration project. Energy projects, notably solar and fossil, but also (against the administration's will) the Clinch River fast breeder reactor, are the chief victims.

Basic research

Dr George Keyworth, the President's science adviser, has been taking pains to cast this budget as staunchly pro-science. For the first time, basic research is to receive a larger share of total non-military research appropriations than either applied research or development. Keyworth points with pride, too, to new funds for university instrumentation and training and to the fact that basic research support to universities has grown steadily during Reagan's term, reaching nearly $4,000 million in this year's proposal, an increase of more than 25 per cent in real terms from the level where it had stagnated under the previous administration.

Last week also provided some apparently good news about industry's contribution to US research and development. According to a forecast released by the Battelle Memorial Institute, industrial support is expected to grow by 10 per cent in 1984 to a point where it makes up slightly over half of all US research and development expenditure, public and private.

The emphasis on basic academic research in the President's budget may well stifle complaints that the real increases have been reserved for military projects. If the Reagan budget is adopted, military research and development will have more than doubled (in nominal dollars) in just four years. Most of the military spending supports the new weapons systems to which the Reagan Administration has committed itself, including the Trident II and MX missiles and the B-1 bomber. A significant share of the new funds, however — roughly $250 million — is earmarked for the ballistic missile defence programme (also known as Strategic Defense Initiative or star wars).

Science foundation

On the civilian side, NSF is once again in line to be the big winner, with a 14.6 per cent increase in its budget to come on top of last year's 17 per cent increase. Mathematical and physical sciences and engineering would receive the lion's share of the new money, which includes $10 million for the establishment of "Centers for Cross-Disciplinary Research in Engineering" to focus university research on problems faced by industry and to train graduate and undergraduate engineering students.

The NSF budget also includes a 22 per cent increase in support for scientific instrumentation — a total of $237 million, $122 million of which will be available under research grants to individual researchers with the remainder going to support university-based and national centres. Support for graduate students under research grants will increase by 15 per cent, allowing an additional 1,050 students to participate. And a new half-million-dollar experimental programme will provide women scientists with an opportunity to initiate research projects.

NSF has received the go-ahead to begin construction of the Very Long Baseline Array (VLBA), a network of radio telescopes across the United States. VLBA is expected to offer 100 times greater resolution than any existing radiotelescope.

A modest effort in supercomputing — far short of what advocates had hoped for — is also included in NSF's proposed budget. No new hardware will be purchased, but $20 million is to be made available to pay for access to existing supercomputers and to cover local user costs, such as terminals, software, networks and communication time. In a separate budget item, NSF plans to acquire a new supercomputer for the National Center for Atmospheric Research at Boulder, Colorado.

Energy

The Reagan philosophy is most evident in the proposed budget for the Department of Energy. While overall spending on research and development is to grow by only 1 per cent, basic research is to receive an 18 per cent increase.

Funds will be provided to start construction of the electron accelerator designed by the Southeastern Universities Research Association, which beat Argonne National Laboratory last year in a bitter political fight. Brookhaven National Laboratory, which last year lost another bitter fight to keep its illfated ISABELLE accelerator alive, is to receive its expected consolation prize of $15 million for a tunnel that will link its existing van de Graaf accelerators and synchrotron, creating a new heavy-ion facility. A plan to incorporate the ISABELLE ring to create a massive relativistic heavy-ion machine is apparently still several years away.

The energy budget also provides support for initial studies of the Superconducting Super Collider concept in order to establish its feasibility and then to produce a specific design in several years.

Keyworth's pet project at Lawrence Berkeley Laboratory, the Center for Advanced Materials, has survived a year of criticism and, having lost its synchrotron advanced light source and the prefix "National", is to receive $11 million with which to continue construction.

This year, the administration has taken a ▶

President Reagan's 1985 budget for research and development, fiscal years (1 October–30 September) 1984 and 1985

different approach to its perennial battle with Congress over the National Institutes of Health (NIH).

In past years, the tactic has been to ask for no increase for NIH in the knowledge that Congress in its rapture with that most popular of scientific agencies will add too much anyway. The administration has become increasingly concerned, however, that Congress's enthusiasm tends to be channelled into advocacy for narrow, disease-specific research, a tendency that threatens NIH's traditional freedom to support valuable but less glamorous basic research. "The 'disease-of-the-month club' syndrome is no longer a joke", Keyworth said recently.

This year, the administration is proposing to give NIH an additional $102 million, but specifically for areas of basic research that it believes have been neglected, such as neurobiology. Keyworth said he hopes that this proposal will "open a dialogue" with Congress and will give the administration a chance to air its views on the importance of basic research in the life sciences — particularly its role in underpinning US competitiveness in biotechnology.

The Environmental Protection Agency, which in past years has felt the full weight of the administration's budget-cutting, is in for a modest increase this year in research funding. The news may not cheer the environmental lobby, however, as much of the new money will go for further studies of acid rain at a time when many — including a panel that Keyworth himself assembled — have concluded that enough studies have already been done to support regulatory action, a step at which Reagan still baulks.

The National Oceanic and Atmospheric Administration (NOAA), the National Bureau of Standards (NBS) and the US Geological Survey are all in for major cuts in support for research and development on the principle that much of their research belongs in the private sector.

Particularly hard hit is NOAA, which is to lose a full one-third of its $242 million research and development budget. And NBS's fire and building research centres are once again under threat of closure.

Stephen Budiansky

Agricultural research

Towards grant competition

Washington

THE US agricultural system, which has been repeatedly criticized for fostering mediocrity and neglecting basic science, is in for a major shake-up if the Reagan Administration has its way. The 1985 budget proposal would triple the size of the small programme of competitive grants for agricultural research, bringing it up to $50 million, the maximum level currently authorized by law. The bulk of the new money would be reserved for basic research related to biotechnology.

Under the administration's proposal, most of the federal funds for sponsored research in agriculture would continue to be distributed to the country's land-grant colleges according to a state-by-state formula not involving peer review. But by rapidly expanding the competitive grants programme beyond its token level of $17 million, the administration hopes to effect a major change in the way agricultural research is carried out. The expanded programme is expected to attract researchers at non-land-grant universities (among them the leading US basic research centres, such as Harvard and Stanford Universities) which are shut out from the formula-fund system. It may also bring some scientific rigour, by way of peer review, to a system often accused of drifting more and more to applied research of dubious scientific merit.

The new money, £33 million, is to come in part from an overall increase in the research budget of the Department of Agriculture (USDA) and in part from the phasing-out of the so-called "special grants", funds earmarked, usually by Congress, for specific projects.

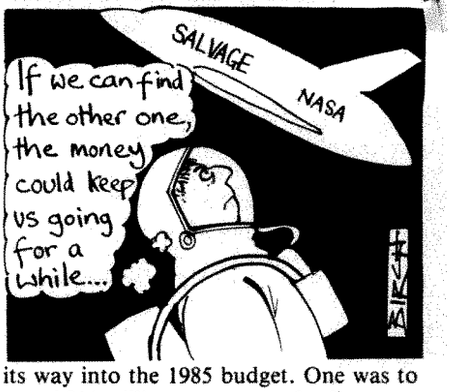
Congress has baulked at past efforts to expand the competitive grants programme, which the smaller land-grant colleges in particular see as a threat to their assured support from the formula funds. This time things may be different. Many of the larger and scientifically more competitive land-grant institutions have broken ranks and have declared themselves in favour of an enlarged competitive grants programme. And both Secretary of Agriculture John Block and presidential science adviser George Keyworth have taken a personal interest in the programme.

Besides the new effort in biotechnology (which would receive $28.5 million), the administration's proposal would establish a small effort in animal sciences ($4.5 million); existing components in plant sciences ($15 million) and human nutrition ($2 million) would continue. Approximately one-quarter of the competitive research funds would be expected to support graduate research assistants working under project grants.

The National Science Foundation's plant biology programme, which has traditionally taken up the slack in basic plant research, is also due for an increase under the President's budget — a 16 per cent rise, to $58 million.

The USDA formula funding would grow by 2 per cent next year; and Department of Agriculture's own in-house research arm, the Agricultural Research Service, would receive a 3 per cent increase. Beltsville is not to be frozen out.

Stephen Budiansky



Space science

Panel's advice ignored

Washington

SPACE scientists are unlikely to give more than two cheers for the 1985 budget request for the National Aeronautics and Space Administration (NASA). The agency's basic research receives a hefty increase to $828 million and three important new projects — the Mars Geoscience/Climatology Orbiter, the Upper Atmosphere Research Satellite and the Scatterometer experiment — have been given the go-ahead. But NASA has unexpectedly baulked at a plan to inject urgently needed new funds into university research groups.

The plan, devised jointly last year by university space scientists and NASA officials, carried the *imprimatur* of Frank McDonald, NASA's chief scientist. Yet neither of its chief recommendations found

its way into the 1985 budget. One was to spend $11 million extra a year for five years to buy new equipment for universities — chiefly oscilloscopes, spectral analysers, computers, micro-ion probes and gas analysers. The other was to resurrect the NASA graduate fellowships that helped build up university space science in the 1960s.

Worse still, the budget contains no increase for basic research grants for university space science. Support for physics and astronomy is held at the same level as last year, while the amount for planetary science is reduced. Only one important recommendation of the McDonald report — more money to analyse mission data — has been incorporated in the 1985 request. Funds for space shuttle operations are due to rise from $81 million to $105 million, but that is not expected to be enough to make shuttle science significantly cheaper or faster; since 1978 there has been a backlog of experiments waiting to fly.

NASA's overall budget increase is a scant $274 million, or 4 per cent. That is enough, however, to keep alive major projects such as the Space Telescope (now renamed the Hubble Space Telescope), the Galileo mission to Jupiter and the Venus Radar Mapper. For 1985 only $150 million is allocated for research on the proposed space station.

US military research

Caltech to expel Army think-tank

Pasadena, California

A US Army think-tank set up at the California Institute of Technology (Caltech) is to be closed at the urging of the faculty. Growing concern over the think-tank, known as the Arroyo Center for Army Analysis, led last week to an emotional two-hour faculty meeting at which Caltech's president, Marvin Goldberger, was criticized for having allowed the centre to be established under what could be viewed as Caltech's auspices. The faculty urged Goldberger to sever ties with the centre "expeditiously and in a responsible fashion at the earliest possible time".

Goldberger said he would honour the faculty's wishes, but that the university would meet its existing commitments to the Army. The centre could thus keep its ties with the university for up to three years.

The centre is the Army's first outside think-tank. Its mandate is to examine future needs of the Army and to carry out objective analyses of policy questions. It was hoped that association with a leading university would give the centre an air of independence and attract good people.

The Army got its foot in Caltech's door by way of an expanding relationship between the Department of Defense and the Jet Propulsion Laboratory (JPL), the Pasadena space research centre operated by Caltech for the National Aeronautics and Space Administration (NASA). Three years ago, NASA slashed its support for JPL, most of whose planetary exploration missions were shelved. The Caltech faculty, saying it wished to preserve JPL's "unique" research teams, with some trepidation authorized JPL to accept up to 30 per cent of its support from the Department of Defense, and the proportion has indeed grown to 12 per cent (roughly $50 million of its $425 million budget).

Ironically, NASA's fortunes have rebounded in the past year, and JPL is now busy with a new mission to Venus and several smaller projects. Nonetheless, Goldberger and JPL's director, Lew Allen (a former Air Force chief of staff), have continued to encourage the military to invest in JPL's future. The Arroyo centre was seen as a "goodwill gesture" to the Army — and a direct link with the Army's upper echelon. The centre now has 23 employees, a director and a separate facility at JPL.

The Caltech faculty began to be concerned about the centre last autumn. "We were told everything was exploratory", said one faculty member, "but real commitments were being made." Last week's "Faculty Discussion" — a special session called only when serious matters need airing — concluded that the Army centre does not fit in with Caltech's strengths and expertise. A particular concern was that Caltech could be seen as lending its reputation to the policy recommendations made by the centre. Although 60 per cent of the Caltech faculty have individually consulted for the military, 95 per cent say it is wrong for the university to enter into an institutional arrangement with them.

Goldberger said that there had been a breakdown in communications with the faculty on the issue and that "all the worries should have come up sooner". He said that Caltech and the Army have yet to work out the details of how the centre will be operated in the light of the faculty's recommendations.

Sandra Blakeslee

US foundations

Kettering changes course

Boston, Massachusetts

A SMALL drama of scientific tradition confronted by unavoidable change is being played out in Ohio. As part of a major shift of focus of its research, the Charles F. Kettering Foundation of Dayton, Ohio, is arranging to hand over the Kettering Research Laboratory of Yellow Springs to the Battelle Memorial Institute, the large non-profit contract research organization in Columbus, Ohio.

The Kettering Laboratory has built its reputation over the past 50 years on basic research in the plant sciences, concentrating on nitrogen fixation and photosynthesis. It has some twenty senior scientists in a staff of eighty. In the past, 60 per cent of its financial support has been provided by the foundation, most recently to the tune of about $1.6 million a year, while the remainder has been made up of federal grants and some contracts.

The foundation announced the new arrangement in May 1983, and Battelle took over management of the laboratories last September. Assuming that the Internal Revenue Service approves the merger, the deal will be completed in the next few weeks. The Kettering Foundation will provide $8 million over the next five years to maintain current operations during the laboratory's adjustment to becoming part of Battelle.

Battelle, a public trust whose charter states that it must "benefit mankind", and whose net income is disbursed to charity through the Battelle Foundation, carries out applied contract research for clients in such areas as metallurgy, information sciences and organic chemistry. Battelle is otherwise similar to a profit-making business: it must generate income by selling its work to government and industry.

The expected changes are worrying the laboratory's staff, used to functioning independently in an academic atmosphere and focused primarily on long-term non-applied questions. One leading investigator asserts that he and about half of the senior staff at the laboratory are seriously hunting for other jobs. Under the new regime, members of staff will deal with novel concepts such as "deliverables" and "marketing", anathema to many of them, and will be responsible to Battelle management.

Albert Adelman, associate director of Batelle Columbus, claims that he and his staff are trying to make the changes as easy as possible for those at the laboratory. Battelle has asked everyone at the laboratory to stay on. It is consulting the staff about major decisions, particularly in the search for a new scientific director, and new people with more experience in business will be phased in gradually.

The question remains of why the Kettering Foundation decided to divest itself of the Kettering Research Laboratory. Kettering is an "operating foundation", meaning that more than 80 per cent of its endowment income is channelled into its own projects. In addition to the laboratory, the foundation has supported social science research, including an international affairs programme, the Institute for Development of Educational Activities and an urban management programme. All three have either been gutted or spun off since 1981, when David Matthews, Secretary of Health, Education and Welfare under President Gerald Ford, became president of the board of trustees.

According to Robert Daley, director of public affairs at the foundation, the decision to transfer the laboratory to Battelle was made by the trustees to "ensure the long-term growth of the laboratory". He claimed that Battelle was chosen because it would be better for the laboratory to be associated with a larger international company with wide experience in research management. He says that the laboratory staff were informed of the decision-making process, but at least two senior researchers insist that the announcement of the merger plan last May was a complete surprise.

Meanwhile, the Kettering Foundation has turned its attention to matters of public policy. It now supports a Domestic Policy Association whose goal is to foster public understanding of federal policies. It is also developing other programmes to educate the public about government, says Daley.

The Kettering Laboratory was founded in the late 1920s by the successful inventor and entrepreneur Charles F. Kettering "to sponsor and carry out scientific research for the benefit of humanity", particularly in plant science and agriculture. Despite the foundation's contention that it is maintaining Kettering's original trust, many staff members feel betrayed by what they see as abandonment by the foundation and its trustees of its essential purpose.

European information technology

Only one dog left in manger

Brussels

WEST Germany will agree to contribute its share towards Esprit, the £1,000 million Brussels-inspired European research programme on information technology, at a meeting of research ministers later this month. So, at least, European Commission sources believe after the visit to Bonn by research commissioner Etienne Davignon two weeks ago.

In the past six months, Britain and West Germany together having been blocking progress on the project pending a wider European agreement on the budgetary problems of the European Communities. But now, it seems, Britain may be the only obstacle.

According to Brussels, West German opposition was limited to tying a release of Esprit funds to an offsetting reduction of the whole Brussels research budget (which is dominated by energy, including nuclear fusion). But, it seems, Bonn has been convinced that such a move would be counter-productive: the Brussels research directorate has recently been putting its house in order, and, Davignon argues, is ready to take on more work.

Thus, with West Germany ostensibly out of the way, Davignon is turning all his attention to Britain where the nut will certainly be harder to crack. Not only has the United Kingdom set up its own information technology programme under the Alvey directorate (on a scale roughly equivalent to what Britain might get out of Esprit), but the British Prime Minister insists on a complete solution to the European budget issue before new spending is approved. Davignon seeks to tackle this policy at its source.

Ironically, the Esprit sums for 1984 are already written into the current Brussels budget, but cannot be released until the ministers agree. Frustrated, the Commission is already unofficially preparing the official "call for tenders" that would follow ministerial approval. The hope is that after 28 February (when research ministers will meet in Brussels) the Esprit motor will be warmed up and running, just waiting to leap off the grid in its race against Japan and the United States.

Meanwhile, the European Commission has managed to get at least one new technology project under way: an eight-laboratory effort, costing £1 million, to produce the semblance of a working, optical computer within two years.

Esprit, although considered advanced and pre-competitive by industry, does not include "optronics", considered by some as the real future of computing and by others as a mere dream. But Esprit has now been all but taken over by the Brussels industry directorate, leaving the research directorate to look further ahead.

This it certainly has done. One goal of optronics is a thousandfold increase in computing speeds (to picosecond rather than nanosecond switching times) but there is at present no demonstrable read-write memory or clock working at these rates. But the optronics programme, which has been under way for little more than a month, will put Europe ahead of the United States and Japan in these fields, according to one of its co-directors, theorist Dr P. Mandel of the University of Brussels.

The eight groups involved, at Heriot-Watt University (Glasgow) (where Dr S.D. Smith is director of the experimental part of the European project), Milan, Pisa, Strasbourg, Frankfurt, Freibourg, Munich and Brussels, knew of one another before the Commission programme was mooted, but they are now working together with a will, claims Mandel. **Robert Walgate**

UK data protection

Reservations over data bill

THE British Government's Data Protection Bill successfully ran the gauntlet of its second reading debate in the House of Commons last week, despite Labour opposition and public reservations by several professional bodies.

The bill, which has been controversial from the start (see *Nature* **302**, 641; 1983), sets out to prevent the abuse of personal information held in machine-readable form so as to allow Britain to ratify the Council of Europe's convention on data protection. But many fear that the vague terms employed in the bill and the wide scope of its exemptions from this laudable aim will make it a burden on companies which would be required to register as "data users" while providing no worthwhile protection to people about whom data are held, "data subjects" as they are called.

Soviet computing

Aleksandrov urges speed

ATTEMPTS to computerize the Soviet economy could turn out to involve "vast and futile expenditure", Academician Anatolii P. Aleksandrov, president of the Soviet Academy of Sciences, has been warning. Writing in *Izvestiya*, Aleksandrov alleges that the Soviet Union is failing to make proper use of "even the comparatively small amount of computer equipment" that it manufactures.

The main bottleneck, according to Aleksandrov, is the shortage of trained personnel in the Soviet Union and a lack of awareness of the potential of computers among the population at large; overcoming these deficiencies will be a task comparable with "eleminating illiteracy" after the revolution.

Aleksandrov's article is ostensibly a call for a massive training programme, with the necessary computer manuals produced "before 1985", tuition in computer sciences (already partially implemented in tertiary education) at the secondary level and salary incentives for employees who complete computer familiarization courses.

Computers and automation equipment, Aleksandrov urges, must be "highly reliable", with at least 3-5 years of "trouble-free working". Accidental power failures, he said, should not lead to loss of information or to damage.

The situation with software is more complicated. The introduction of computers into the Soviet economy has taken place piecemeal, so that the various designers and ministries have produced equipment which, although "quite good for its time", is incompatible in software and components.

The need therefore is for a major overhaul of the Soviet computer industry so that all future hardware and software would be compatible. The logistical implications of such a revision of plans would be considerable — particularly in the Soviet context, where quarterly, annual and quinquennial production targets make no allowances for retooling or changes of production lines. If a switch to fully compatible hardware and software is decided, the planners will be hard pressed to incorporate it into the directives for the 1986–1990 five year plan.

The technical quality of existing Soviet software, to judge from Aleksandrov's remarks, is not entirely satisfactory. Existing tasks in the software sphere, he says, include the adaptation of software to automatic search systems and the protection of software against distortion due to voltage or frequency fluctuations, electromagnetic interference and the like.

For Aleksandrov, however, the task is clearly that of education. His programme for computer education (if the comparison with the literacy campaign of the 1920s has any real meaning) would embrace about half the population of the Soviet Union. Such a programme would itself require a major coordinated effort and, according to Aleksandrov, even the production of computer education manuals ("before 1985") must be preceded by work by the State Committee for Science and Technology, the Academy of Sciences, all ministries manufacturing computer equipment and automation facilities and the ministries of higher and secondary education, in order to "integrate" the available technical resources and software. **Vera Rich**

The several amendments agreed by the House of Lords have not been enough to satisfy the critics. Holders of personal data stored in machine-readable form — subject to certain exemptions — would be required to register with a new Data Protection Registrar, who would keep records on the sort of information being held. (Personal data, as defined in the bill, include expressions of opinion about individuals but not indications of data users' intentions regarding those individuals.) Data subjects — subject to further exemptions — would be allowed access to information held about them and would be entitled to demand that any inaccuracies be corrected. Data users, for their part, would in general be prevented from unauthorized disclosure of personal information — again, subject to exemptions.

It is the exceptions to the general principles of the bill that arouse anger. The main concern of the British Medical Association is that computerized medical records would, if the bill became law, have to be registered, presumably by the health authorities, whose representatives — including non-medically qualified personnel — would then be empowered to pass on such records either to the police or to the Inland Revenue. The medical profession considers this quite unacceptable.

The British Medical Association (BMA) and a medical inter-professional working group on personal information have been negotiating with the Department of Health to find a solution to the problem. The department has offered some concessions based on voluntary codes that would in any case apply only while records were within its purview. BMA and the working party want medical records to be specifically exempted from the general provisions of the bill so that they could only ever be disclosed to an outside authority on the order of a crown court judge. At the same time the bill must not interfere with epidemiological research.

An earlier blanket exemption from the bill's subject access provisions and prohibitions on disclosure for data relating to immigration control has now been dropped, but it seems that the Home Secretary retains the power to exempt much government-held data from subject access "if they appear to him to be of such a nature that their confidentiality ought to be preserved". Universities are worried about the possibility of having to hand over their students' academic records on demand. And although data subjects who do manage to establish that inaccurate information about them is being held do not now have to prove damage in order to be awarded compensation, this does not apply if the data are improperly disclosed, a surprising omission picked up by Liberal Member of Parliament Mr Simon Hughes.

Quite apart from these sensitive issues, many fear that the proposed system for control of computerized personal data would be quite unworkable. The Data Protection Registrar would probably have a staff of about 20; the number of data users who would have to register would be of the order of hundreds of thousands, many of them holding entirely innocuous information. The definitions in the bill are so vague that it is unclear whether many computer systems will be required to be registered or not. The bill contains no detailed guidelines or codes of practice to help data users, and some Members of Parliament have suggested simple devices that would enable the letter of the bill to be complied with while breaking its spirit — for example, maintaining different (but unlabelled) lists for (say) creditworthy and uncreditworthy customers.

Those who defend the bill point out that as there is now no protection against the abuse of personal data in British law, the bill must at least be an improvement. But this would be to forget that once an important bill becomes law, major modifications are unlikely to be made for some years afterwards. Liberal and Social Democrat Members of Parliament who voted for the bill say they will be pressing for further changes in the committee stage. But the committee will be very limited in the expert opinion on which it will be able to call, and a Labour move to put the bill before a special standing committee was heavily defeated. However, the Home Secretary appears willing to accept that further modifications to the bill will be necessary.

Tim Beardsley

Fast reactors

Anglo-French accord at last

THE British and French electricity utilities have agreed on an outline programme of fast reactor development.

Sir Walter Marshall for the Central Electricity Generating Board (CEGB) and M. Jean Guilhamon for Electricité de France (EDF) signed a document on Tuesday which "sets out principles for long-term cooperation" covering the joint construction of fast reactors. According to CEGB, the first such joint reactor would be built in France, while the locations of future stations have yet to be decided.

In the short term, this implies CEGB support for the building of Superphénix II, a putative successor to the 1,300 MW Superphénix I now nearing completion near Avignon. Previously, EDF has shown itself cool to the Superphénix II project because of its probable cost (about twice that of an equivalent pressurized water reactor (PWR)).

Sir Walter Marshall said on Monday that the CEGB contribution to a Superphénix II would be "neither large nor trivial", and certainly more than 16 per cent. CEGB would receive electricity and revenues in proportion.

Assuming this more advanced reactor would cost no more than 40 per cent more than an equivalent PWR, the electricity so bought by CEGB would be cheaper than electricity made by burning coal in the United Kingdom, said Sir Walter.

According to M. Guilhamon, EDF is aiming to start Superphénix II in 1986. "Breeders are easier to operate than PWRs" said Guilhamon. Breeder operators suffer less exposure to radiation, and the thermal inertia of the sodium cooling circuit offers greater protection against accident, Guilhamon claimed. The sodium is unpressurized, and normally runs at 500°C; but it must reach 1,000°C before it boils. The water in a PWR, however, is superheated. This gives a PWR a 20 minutes safety margin but a fast breeder reactor two hours, he claimed.

Sir Walter would be happy to see just one British demonstration fast reactor before 1997 (his retirement date), he said. The main constraint was not cost but the "exhausting" prospect of a public inquiry probably longer and larger than the current Sizewell inquiry into the proposed British PWR. This has been "psychologically very difficult" said Sir Walter. Sizewell must be well out of the way before another such inquiry were contemplated.

Meanwhile, further agreements between British and continental agencies are expected, following the outline inter-state agreement on fast reactor cooperation signed in January. One between the UK Atomic Energy Authority (UKAEA) and its European partners is taking longer than promised — but as this shares out the research among signatories, and as research is the main component of fast reactor work at present, the delay is not surprising. A UKAEA spokesman pointed out wryly that while the CEGB–EDF agreement was between only two agencies, the research agreement involves several in a number of countries.

In fact, some years ago UKAEA had been seeking just such a bilateral agreement — but with the United States rather than France. The authority hoped that the trouble over federal support for the Clinch River project would lead the United States to fall into the arms of a British collaboration; but the US fast breeder programme was finally seen to be so confused and irretrievable that the decision was made to join in with Europe.

It may be considered significant that Sir Walter Marshall, who as the then chairman of UKAEA was behind the approach to the United States, has now also concluded a bipartisan agreement (though this time with France) as chairman of CEGB. Sir Walter approves of clarity, and it may have been against his taste to negotiate with a plethora of European agencies (as are involved in the existing European consortium behind Superphénix I).

UK drug trials

Row over student trial

EVENTS have forced the British Medicines Commission into an urgent study of arrangements for testing new drugs on healthy volunteers. The issue has come to a head in the wake of complaints that plans for testing a new antitumour drug among London students are ethically objectionable and pay scant attention to the safety of the volunteers.

The disputed study, begun some months ago but now abandoned, was being carried out by a company known as Charterhouse Clinical Research Unit Ltd, on behalf of the manufacturer, Ortho-Cilag Pharmaceuticals Ltd. Volunteers, mostly students,

were paid £250 to be given 20 consecutive doses of up to 450 mg of hydroxyphenylretinamide (HPR), an analogue of vitamin A shown to be a tumour inhibitor in animals.

The study, designed to provide information of toxicity in human beings, has been criticized on the grounds that volunteers were not fully informed of the risks and that the testing company had failed to make adequate arrangements for monitoring participants' health. Inevitably, the result has been to reopen the contentious question of how clinical data on the effects of new drugs should be gathered — and of the role of academic pharmacologists in the process.

Under present arrangements in Britain, drug studies with healthy human volunteers are regarded as a private matter between consenting adults — the drug company and the volunteers. Since 1981, manufacturers have not been required to seek advance approval from the Committee on the Safety of Medicines (established, like the Medicines Commission, under the 1968 Medicines Act). One result has been the emergence of a number of companies linked with academic departments to provide human toxicity testing as a service to pharmaceutical manufacturers.

The whistle seems to have been blown on the Charterhouse trial by Professor Brian Rabin, professor of biochemistry at University College, London, who says HPR may plausibly accelerate the growth of some tumours, and who complains that Charterhouse had provided no information to the volunteers' own physicians and that it had no plans to follow up its volunteers to detect long-term untoward effects. He also attacks the information sheet given to volunteers for failing to list all possible side-effects of HPR and says the silence of Charterhouse's consent form on the matter of compensation in the event of damage being suffered is "totally disgraceful".

These criticisms are rejected by Professor Paul Turner, an adviser to Charterhouse and director of clinical pharmacology at St Bartholomew's Hospital Medical College. He says that "ill-considered remarks" and "destructive press coverage" have severely impeded research on a promising anti-tumour drug "showing no signs of toxicity".

Turner says that Charterhouse accepts work only on the condition that a written indemnification against damage claims is provided by the client company. A new consent form being drawn up by Charterhouse will aim to comply with a recommendation of the Association of British Pharmaceutical Industry that no-fault compensation should be offered explicitly to volunteers. Turner argues that new drugs such as HPR are best tested in an independent company separate from the manufacturer.

Although the HPR study had been approved by Charterhouse's own ethics committee, the deans of the London medical schools have now recommended that their students should take part only in studies that have been subject to independent scrutiny. Under a new agreement between Charterhouse and the Metropolitan Conference of Medical Deans, studies on students will in future be approved by the ethics committee of St Bartholomew's Hospital, with which Charterhouse is closely associated.

Although many British pharmaceutical manufacturers have in-house testing units, more and more volunteer studies have recently been carried out by small independent companies, often associated with pharmacology departments in medical schools, whose earnings can provide a welcome source of research funds. Charterhouse Clinical Research Unit Ltd was set up by Synthelabo, a non-profit charity linked to St Bartholomew's Hospital Medical College.

The demand for volunteer studies has grown rapidly since the introduction in 1981 of the Clinical Trials Exemption Scheme, which allows manufacturers with a good case for a drug to go into clinical trials without first facing a full-length scrutiny by the Department of Health's Committee on the Safety of Medicines. It is widely believed that a good volunteer study increases the chances of an exemption certificate being granted.

Practice varies from one company to another: some, such as Drug Development (Scotland) Ltd, linked to the University of Dundee, routinely notify volunteers' physicians about studies. Dr John McEwen, the company's medical director, says that information from volunteers' physicians has often proved useful to those running the studies. The company also offers no-fault compensation in the event of claims for damages, and is insured to cover any claim.

The Medicines Commission, which advises the government on matters related to medicines generally, now has some difficult questions to face. Members will certainly be mindful of Professor Turner's warning that if drug development is hampered in this country, the big manufacturers will simply pack their bags and go elsewhere.

Manufacturers feel hard done by because more is expected from them and from their pharmacological agents than from academic researchers in, say, physiology. Thus in the event of harm to a volunteer in an experiment by an employee of the Medical Research Council, the council would offer an *ex gratia* payment but there would be no legal redress unless negligence could be proved. The voluntary code on compensation to which most commercial companies adhere commits them to damages in a way the Medical Research Council and the Department of Health have been unwilling to apply to themselves.

Tim Beardsley

France seeks rules

THE testing of new drugs in France is to be tightened up, in a move by the ministry of health. No precise bill is yet on the table, but a "draft project" is under study, according to the French evening newspaper *Le Monde*.

French law on the matter is obscure, with some experts claiming that human tests are totally illegal. Testing has nevertheless been carried out, but often in a clandestine and unsatisfactory manner, making France — according to some — an effectively liberal regime in which multinationals can conveniently try out new formulas.

According to the ministry's draft, however, subjects and the authors of trials should sign clear written agreements with each other; payment should be according to published terms; authors would have the burden of proof; and prisoners, or members of the author's staff, would not be used as subjects unless it would be to the benefit of their health. Further, all human trials would be subject to the approval of a regional ethical committee — though the constitution of such a body remains, for the moment, undefined. Robert Walgate

Sahel drought

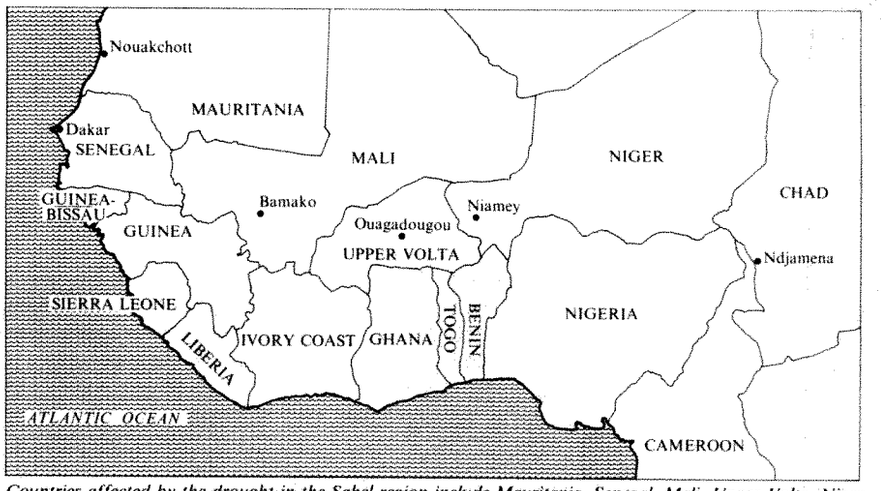
Call for joint action

A CALL for the formation of a Sahel fund to combat the area's drought and desertification was issued last week at the end of the sixth meeting of the Permanent Interstate Committee for Drought Control in the Sahel (CILLS), at Niamey, the capital of Niger. The committee was formed ten years ago by eight West African governments (Cape Verde Islands, Chad, Gambia, Mali, Mauritania, Niger, Senegal and Upper Volta) to coordinate action during severe droughts. The sixth meeting was attended by heads of governments and the director-general of the Food and Agricultural Organization.

The World Meteorological Organization considers that the drought in Africa which began in 1968 has not yet ended, and is worst in the Sahel. Agencies working in the area report that although conditions in the Sahel are not everywhere as serious as in 1968–73, drought is now locally severe in the north. For example, in Mauritania, 85 per cent of the basic cereal crop has failed, with the result that half the population is now gathered in the capital of Nouakchott. In northern Mali, all cereals are badly affected. In Upper Volta, millet has failed entirely and the sorghum crop is poor. So a return to the conditions of the 1970s is feared. Ghana, with its third consecutive poor harvest and an increase of 10 per cent in population since the expulsion of Ghanaians from Nigeria, is expecting a fourfold increase in food prices within six months. In Senegal the cereal situation is disastrous, with animals dying and water holes drying up. But in the southern areas, harvests have been adequate and there are even some surpluses.

Water is the main problem. It is estimated that only 25–30 per cent of Sahelians have access to sufficient water. Desertification, which according to the United Nations Environment Programme, consumes 1.5 million hectares of potentially productive land a year, is exacerbated by population growth (2.7 per cent a year) and overgrazing.

Wood consumption (90 per cent of it for burning) is also a worry, especially because attempts at reafforestation have not been encouraging. The area could show a substantial surplus if consumption were reduced by even one per cent.



The effects of physical problems are made worse by the chronic social and economic conditions of the region, including inadequate transport, low farm prices, which discourage the production of food, and a general insufficiency of money. Emergency aid is difficult to deliver.

According to the Club du Sahel, formed by the Organization for Economic Cooperation and Development and several West African governments and various development agencies, aid to the area has doubled in ten years and now amounts to 15 per cent of the total gross national product in the Sahel states and more than 20 per cent of the gross national product in half of them. So dependent on aid has the region become that some agencies now fear that long-term massive food aid is sapping the ability of the region to acquire the resources necessary to respond to normal climatic swings, let alone to cope with disaster. Oxfam, the British charity, agrees with the UK Overseas Development Administration that the best help is the swift delivery of emergency food aid followed by agricultural aid, such as the supply of seed corn, as conditions improve.

One novel possibility is that climatic change and crop yield may be predictable from satellite data (see p.528 for a study of satellite results); this would be especially valuable if there is a recurring pattern comparable with the 10-year cycle now established for Botswana. A British project is currently under consideration by the Overseas Development Administration and the Food and Agricultural Organization. The World Meteorological Organization, however, considers that drought cannot be predicted and that there is no practical method of enhancing precipitation, but that much could be done to ameliorate the effects of droughts by improving agrometeorological monitoring services and the wide application of increased information on an interdisciplinary basis.

Conditions in the Sahel are part of a climatic threat to the world's poorest people. Nine Southern African states also made an emergency appeal last week. Oxfam, in common with other international agencies, has received more requests for help in the past six months than at any time in its entire 40-year history. Abnormal weather, Oxfam says, could lead to "the collapse of development across a whole sweep of countries so economically depressed that they cannot possibly cope themselves".

Sarah Tooze

Countries affected by the drought in the Sahel region include Mauritania, Senegal, Mali, Upper Volta, Niger, Nigeria, Chad and Ghana.

The day before

SIR — In a leading article in *Nature* of 1 December 1983 (p.412) it is recommended that ABC show the film "The Day After" again, and then again, in order that people do not forget the effects of an all-out attack with megaton weapons which have been extrapolated from the known effects of the 20 kiloton explosions over Hiroshima and Nagasaki.

I was struck by what seem to me to be significant omissions about what happened the day before: the actors portrayed in the film made almost no organized effort to improve their chances of survival. There are two scenes showing men shovelling small quantities of earth against the foundations of a church and a farmhouse, while there are innumerable scenes showing people panicking in city streets, grocery stores and on the highways. In one scene Dr Oats, the senior surgeon-haematologist, washes his hands at a scrub sink while an orderly tells him, in a tone of voice appropriate for the revelation that skinned cats have been found in the hospital kitchen, and that there is a rumour that people are leaving Kansas City. The question is asked, "Where does one go from Kansas City?"

It would have been even-handed and more interesting had the producers of the ABC film shown that the people of Kansas City could have moved into the large complex of commercially developed caverns which underlie the city and its environs. These caverns were artificially excavated out of limestone to provide crushed rock for the Kansas and Missouri interstate highways. The excavated areas are covered by between 80 to 200 feet of bedrock and soil, have an even temperature (57–62° F), a large area (several hundred acres) and are connected to each other and to the surface by many miles of roads and railroads. The Monsanto and Libby food companies have stored very large quantities of canned food and frozen fruit juice in the caverns, and other companies have stored cars, tractors and vodka. It has been estimated that everyone in Kansas City is within 45 minutes of one of the entrances to these caverns, and that the caverns could be used for blast and fallout protection[1].

Few cities have the opportunities for evacuation comparable with those of Kansas City, but then few cities are located beside 150 Minuteman missile silos. It has been estimated that an all-out attack with megaton weapons would kill or injure 50–80 per cent of the unprotected population of the United States, and that the destruction of hospitals would make it impossible for physicians to "intervene effectively in the (resultant) human injury and death"[3]. These speculations have been repeated so often that many authors accept them as fact[3,4]. However, these estimates assume that urban populations remain unprepared and unprotected. Most of the casualties from megaton weapons would result from the blast effects, and by removing people from the likely target areas, evacuation could substantially reduce the number of deaths[5].

In a broader context, it is critically important that the superpowers and their allies keep talking in order to reduce as much as possible the number of nuclear weapons and the likelihood that any of those weapons will ever be used. Until such talks have borne generous fruit, the nations of the Northern Hemisphere would be wise to emulate Sweden, Switzerland and the Soviet Union and improve their civil defence capabilities.

Crucifixion date

SIR — I read with great interest the review article by Humphreys and Waddington entitled "Dating the Crucifixion" (*Nature* **306**, 743-746; 1983). The date of 3 April, of the year AD 33, the 14 Nisan of the Jewish Calendar, appears to be well supported by their evidence. But one of their statements may be in error. They write ". . .we note . . . that the Crucifixion must have occurred on 14 Nisan and that the interpretation of the Last Supper as a Passover meal held at the official time cannot be correct". However, it is likely that the official time for the Passover meal in AD 33 was on the night of 13 Nisan. In support of this view I present the following paragraph from p. 326 of *Jesus of Nazareth* by Joseph Klausner (Macmillan, New York, 1944).

> "According to the ruling which was newly promulgated by the Pharisees in Hillel's time, the Passover was regarded as a *public* sacrifice; if, therefore, the 15th of Nisan fell on a Sabbath and the 14th on the eve of Sabbath, the Passover was sacrificed on the eve of Sabbath (the 14th of Nisan) at the moment "between the two days", even if this profaned the Sabbath; they used to argue that, like every public sacrifice, "the Passover abrogates the Sabbath rules." According, however, to an earlier ruling, which held good among the priestly party almost to the close of the period of the Second Temple, the Passover was regarded as a *private* sacrifice and one which might not abrogate the Sabbath rules; if, therefore, the 14th of Nisan fell on the eve of Sabbath, they sacrificed on the 13th instead of the 14th, so as not to profane the Sabbath (since they must sacrifice "in the evening at the moment of sunset.") Hence Jesus and his disciples celebrated Passover on the Thursday, the 13th of Nisan, and during the ensuing night of the 14th of Nisan (the night before Friday) they had to celebrate the "Seder", the Passover meal, with its unleavened bread and bitter herbs, instead of on the night of the 15th Nisan."

Animal rights

SIR — Since you have established from recent correspondence that animal rightists are not only cranks but humourless ones to boot, it is without relish that I enter the fray. With one conclusion of your leading article (*Nature* **306**, 527; 1983) I can entirely agree: there are no consistent or universal principles that imbue animals with "rights". A right, then, is not a given, an absolute, but is a function of the culture which accords it. Any right is a more or less widely accepted value built up over time and representing something of which we consider an animal or human should not be deprived.

While I can see no evidence for absolute natural rights of animals, to retain these for our own species while withholding them from other animal species is, in my view, antediluvian — or, to be more accurate, pre-Darwinian. What distinguishes this viewpoint from the ethnocentricity of those tribes whose members believe that they are the only humans and that people of neighbouring tribes can be killed like pigs?

Sir Andrew Huxley, president of the Royal Society, is reported to have asked what importance can be attached to the painless killing of purpose-bred laboratory animals that otherwise would not have lived. Man, according to this belief, has a right to destroy because he fancies that, like a god, he can create life. The surgeon Versalius used to say "I dressed him; God healed him." His antidote — a little humility.

City slickers

SIR — The proposal for an Indian "technology city" (*Nature* **305**, 350; 1983) is welcome, but it is unfair to build such a city exclusively for Indian scientists working abroad. It is important to recruit the best of Indian scientific talent, no matter whether those concerned work in India or in the United States. While some of the best Indian scientists are working in India, not all Indian scientists working abroad are of high calibre.

I think the Government of India should go ahead with its plans but that it should appoint the best persons in the field, whether they are working in India or abroad. This could be achieved by a selection board comprising top ranking experts from India and other nations. There is always a risk that the very best scientists are not offered jobs in India for various sociopolitical reasons, but something has to be done if India is to keep pace with international developments.

Cell and cancer biology meld

The startling similarity of part of epidermal growth factor and the product of a viral oncogene is another leap forward in understanding the basis of cancer. A definite link to human cancer remains elusive.

FOR some time, there has been speculation that many viral oncogenes would turn out to be derived from cellular genes for growth factors or their receptors, so when Waterfield *et al.*[1] and Doolittle *et al.*[2] showed, seven months ago, that one of the two peptides that constitute platelet-derived growth factor (PDGF) is similar in sequence to the transforming protein encoded by the *sis* oncogene of simian sarcoma virus, there was eager anticipation of the next example. That has now materialized with the paper on page 521, in which Waterfield and his associates[3] reveal that an oncogene of a tumour virus of birds is almost certainly derived from the gene for the cell surface receptor for epidermal growth factor (EGF). The result is as dramatic as it will be important for research on normal and abnormal (cancer) growth of cells. But it is not as simple as it appears at first sight.

The EGF receptor gene has been a good candidate for a viral oncogene because[4] it shares with at least five viral oncogenes (of which the prototype is *src* of Rous sarcoma virus) the activity of a tyrosine phosphokinase, that is an enzyme which phosphorylates tyrosine residues in proteins. It has therefore been on the cards that one of the tyrosine phosphokinase encoding oncogenes would closely resemble the EGF receptor gene. If so, the argument went, the tumour virus would in effect be placing an EGF receptor in an inappropriate cell and/or at an inappropriate time. In the event, neither idea is exactly borne out.

The sequence of the *erb-B* oncogene of AEV-H, a strain of the avian erythroblastosis virus that causes erythroleukaemia and, less frequently, sarcoma in chickens, was published last November by Yamamoto *et al.*[5]. Unexpectedly, it contains a segment that is notably similar to the *src* oncogene and others with tyrosine phosphokinase activity. Nevertheless, at least three separate laboratories have since failed to demonstrate that the *erb-B* oncogene product has tyrosine phosphokinase activity of its own (an anomaly shared with the *mos* oncogene[6] and, very recently, the *fms* oncogene[7]). But while the tyrosine phosphokinase activity of EGF receptor has been known for some years, the sequence of the receptor has awaited its purification in sufficient quantities.

Starting either with human placenta or with the human epidermoid carcinoma cell line A431, and with the vital assistance of monoclonal antibodies against the EGF receptor, Waterfield's group has now determined the amino acid sequence of 14 fragments of the receptor. These scraps of information have been sufficient for a computerized data search to align six of the peptides with segments of the protein encoded by *erb-B*, with 74 identical amino acids out of 83. The other eight peptides could not be aligned with *erb-B*.

Waterfield *et al.* conclude that the *erb-B* oncogene represents only part of the EGF receptor gene — cautiously, they raise the formal possibility that it comes not from the receptor gene itself but from a closely related gene — and deduce that the missing part encodes the EGF-binding domain of the receptor which is positioned on the external surface of cells. What the gene retains is the short segment of EGF receptor that spans the membrane and the large segment on the internal surface of the membrane which has tyrosine kinase activity.

The first puzzle is why, then, does *erb-B* not have demonstrable tyrosine phosphokinase activity? One possibility is that it does, but that the activity has been missed, for lack of rigorous testing. If so, the next puzzle is how it can be stimulated when the *erb-B* version of the EGF receptor lacks the EGF-binding domain and the normal receptor has low tyrosine phosphokinase activity in the absence of EGF. A clue to the solution to both puzzles may come from the recent demonstration by Tamura *et al.*[8] of the activation of the tyrosine phosphokinase of insulin receptor by the proteolytic action of trypsin; perhaps the truncation of EGF receptor really does activate it.

It is even conceivable that the tyrosine phosphokinase activity, or lack of it, is not wholly relevant to the issue. Could it be that other activities of viral oncogenes/growth factor receptors are more relevant to cancer? For example, is the recently demonstrated induction of the *myc* gene of lymphocytes as an early response to PDGF[9] a more relevant clue or does that induction anyway depend on the tyrosine phosphokinase activity that PDGF induces in its receptor?

The next question that is likely to be answered by Waterfield and his associates is the intellectually more modest but technically formidable one of what the complete sequence of the EGF receptor looks like. The answer will be derived from the nucleotide sequence of its messenger RNA converted into cDNA. The sequencing is already well under way at Genentech under Axel Ullrich, an author of Waterfield *et al.* The sequence will reveal more clearly the exact relationship between the EGF receptor and the viral *erb-B* gene product. Moreover, a comparison between the cDNAs of EGF receptor and those of the cellular *erb-B* gene[10] will make it easier to decide whether the two genes are identical.

The relevance of the discovery of Waterfield *et al.* for cancers, particularly human cancer, not caused by tumour viruses simply cannot be answered at this stage. It is, at least, clear that activation of the cellular *erb-B* gene by avian leukosis virus, a tumour virus of chickens that does not carry its own oncogene, can cause a variety of neoplasms, particularly erythroblastosis[11]. Therefore, by analogy with *myc* genes[12,13], it is possible that the human cellular *erb-B* gene can be inappropriately activated by, for example, chromosome translocations. A thorough comparison of the expression of *erb-B* EGF receptor genes in healthy and tumour tissues should at least indicate how frequently they are expressed in abnormal amounts or in abnormal sizes (perhaps as a truncated protein) in tumours; the A431 cancer cell line was a good starting point for the EGF receptor purification precisely because it has at least fifty times more receptor than normal cells.

The discovery will also act as a spur to the purification and sequencing of other growth factor receptors, especially those with tyrosine phosphokinase activity — the PDGF, insulin and insulin-like growth factor-1 receptors. Perhaps it is from their genes that some other viral oncogenes have been derived. But it will be necessary to look further afield to account for them all, particularly if the recent identification[14] of about one-third of the gene for actin as part of the oncogene of a tumour virus of cats is relevant to its ability to produce fibrosarcomas.

Neurobiology

More nerve growth factors?

from Joshua R. Sanes

THE discovery of nerve growth factor (NGF) by Levi-Montalcini and Hamburger[1] was the first major step in the molecular analysis of neural development, and remains the most influential achievement in this rapidly growing field. This soluble protein is required for the survival of sympathetic and sensory neurones *in vivo* and *in vitro*: in culture, it also promotes neuronal differentiation and chemotactically directs growing axons. NGF has been purified and sequenced, its genes are being cloned and mapped, and studies of its mechanism of action are underway. The current dogma is that NGF is produced by peripheral target tissues, picked up by nearby axons, and transported back to neuronal somata. Competition for limited supplies of NGF may determine which neurones live and which die during embryogenesis. In addition, NGF may act locally in the periphery as a stimulant and attractant, to regulate the size and shape of an axon's terminal field. Finally, NGF may be required for neuronal maintenance in adulthood, with loss of its supply — after axon injury, for example — signalling the neurone that adjustment or repair is required (reviewed in refs 2–4).

The early realization that only a few types of neurone are sensitive to NGF led to speculation that NGF was but one of a family of trophic agents[5]. If each of several cell types turned out to secrete limited amounts of a factor that supported its own innervation, retrograde trophic control would provide a general means to match the sizes of pre- and post-synaptic populations. Furthermore, a system of selective trophic sustenance might play some limited part in synaptic specificity: that is, in determining which cells or connections, as well as how many cells or connections, form or survive. Among the first steps in the hunt for other trophic factors have been the demonstration that extracts of appropriate targets support parasympathetic neurones *in vitro*[6,7], and the purification of a protein from brain that allows survival of some cultured neurones that do not respond to NGF[8].

From a cell biological point of view, the most useful new factor to obtain would be one that supports somatic motor neurones — a motor neurone growth factor (MNGF). The skeletal neuromuscular junction is the best studied of all synapses and would be a good system for studying factor uptake and action. Fortunately, there is reason to suspect that a MNGF exists, in that several aspects of neuromuscular synapse formation seem to reflect control by muscle-derived factors. In the embryo, spinal motoneurones (like many other neuronal types) are normally produced in excess; 30–50 per cent of them degenerate before the animal is born. Peripheral control of this process is indicated by the observation that the naturally occuring cell death can be increased by extirpation of the appropriate target, while neurones that would otherwise die can be rescued by grafting on extra target tissue. In the neonate, several axons innervate each skeletal muscle fibre. Excess inputs are withdrawn until each fibre receives a single input, and it has been proposed that even after a neurone's survival has been assured, its individual axonal branches continue to fight for the limited support that each muscle fibre can furnish. In the adult, partial denervation of a muscle induces the undamaged axons to sprout and reinnervate the denervated muscle fibres. Again, several aspects of the sprouting phenomenon suggest that it represents an axonal response to soluble factors released by denervated fibres. Thus, neuromuscular connectivity could be regulated in part by the supply and/or effectiveness of MNGF(s) throughout the life of an animal (reviewed in refs 9–12).

How, in turn, might the supply of such growth factors be regulated? Again, previous studies of muscle suggest a candidate: electrical (or contractile) activity. Paralysis of muscle rescues embryonic motoneurones destined to die, slows elimination of polyneuronal innervation in neonates and evokes sprouting in adults; conversely, chronic stimulation speeds synapse elimination and prevents sprouting[8-11]. Since many aspects of muscle metabolism are already known to be activity-dependent, it is tempting to suppose that denervated or inactive muscles secrete more MNGF than innervated, active muscles. Neurones could thus control and be controlled by their supply of factor, establishing a feedback loop.

Aware of these and other issues, many groups have begun to search for a MNGF. The most common approach has been to culture motor (or spinal cord) neurones in a minimal medium, and to assess the effects of adding muscle extracts or muscle-secreted material. Supplements have been found that increase levels of neurone survival, neurite extension, or transmitter synthetic capacity[13-21]. As one might have hoped, extracts are more active when made from neonatal or denervated muscle than from innervated adult muscle[18-21]. Early attempts at fractionation suggest that the extracts may contain several active factors, which differ in their modes of action (some seem to act in solution, others after first attaching to the substratum) and effects (for example, activities that promote neuronal survival and differentiation can be separated from each other). However, purification of the factor(s) has not yet been achieved.

So far, all attempts to identify a MNGF have relied on neurones in culture as bioassay. Now Gurney[22] reports, in this issue of *Nature* (p.546), results of an alternative immunological approach. He used a series of antisera (originally prepared at the MRC, London) to material secreted by organ-cultured denervated muscle. To carry out an assay he injected the sera into paralysed but innervated mouse muscles and looked for suppression of the sprouting that would normally occur. Gurney's paper contains three intriguing results. First, several antisera partially prevented sprouting *in vivo*. Second, each blocking serum recognized a 56,000-molecular-weight (56K) protein on immunoblots of muscle-secreted material. Third, and perhaps most astonishing, sera from patients with amyotrophic lateral sclerosis (ALS) not only blocked sprouting when injected but also recognized a 56K antigen on immunoblots. ALS is a disease in which many spinal motoneurones die and surviving motoneurones sprout poorly. Thus, the properties of ALS sera both provide a possible clue to the aetiology of this fatal disease and lend further support to the notion that a 56K protein may regulate sprouting.

Is the 56K antigen a MNGF? A promising preliminary result is that the antigen is present in an incompletely purified fraction that promotes neurite extension and survival of cultured spinal cord cells (ref. 22 and personal communication). If further work proceeds well, the idea that neurones of different types and of different ages are maintained in a trophic equilibrium will be open to new and exacting tests. □

Solar conversion

Non-aqueous electrolytes make wet cells work

from S. Dennison

IN the urgent search for photovoltaic devices for the direct conversion of solar energy to electricity, solid-state solar cells have in the past few years far outstripped their counterparts based on junctions between semiconductors and electrolytes. Although 'wet' photovoltaic cells may be more easily manufactured, they are far behind as practical converters. But now there is a prospect that this gap may be closed.

At the end of 1982, Stanford University chemists Chris Gronet and Nathan Lewis described (*Nature* **300**, 733; 1982) a cell based on an n-$GaAs_{1-x}P_x$ semiconductor in contact with a non-aqueous redox electrolyte with an efficiency of no less than 13 per cent, a doubling of the best previous efficiency. The problems that had plagued earlier devices were overcome by optimizing the semiconductor properties and preventing corrosion by the use of a non-aqueous electrolyte. Now, Gronet and Lewis, together with C. Lieber, have made an equally impressive step forwards by the construction of a 10 per cent efficient cell based on the rather more familiar material p-type silicon, in a non-aqueous electrolyte containing the cobaltocene–cobaltocinium redox couple (see this issue of *Nature*, p.533).

The efficiency of 10 per cent, obtained both with a laboratory lamp and direct sunlight, dwarfs that of previous cells based on p-silicon, putting it high in any league table of 'wet' photovoltaic cells. At the same time, the Stanford group has demonstrated a major departure from the expected behaviour of p-type silicon in contact with a non-aqueous electrolyte and have shown how certain intrinsic limitations on cell performance expected from the behaviour of the semiconductor–electrolyte interface are not apparent in their cell.

To a large extent, the major problems of the liquid-junction photovoltaic cell (see our discussion, *Nature* **300**, 687; 1982) have been solved by the replacement of aqueous with non-aqueous electrolytes. By the rigorous exclusion of water, semiconductor corrosion is almost completely suppressed. These solvents also allow a far wider range of redox couples to be used, so that difficulties of poor electron-transfer kinetics can be overcome. But the use of non-aqueous media introduced a further complication — an apparent limitation of the photovoltage obtainable from a cell, a phenomenon now known as 'Fermi level pinning'.

The phenomenon is this. With a number of semiconducting materials, the observed photovoltage seems to be more or less constant for each material and independent of the redox couples in solution with which it may be in contact. But on the conventional model of such an interface, the photovoltage should reflect the difference between the redox potential in solution and the Fermi level of the semiconductor. The observation that the photovoltage is substantially constant thus implies a constant difference between the redox potential and the Fermi level, which in turn suggests that the redox couples in the non-aqueous medium are in some way 'pinning' the Fermi level.

The explanation lies in the charge distribution at the interface. On the conventional view, there should be a depletion layer beneath the surface of the semiconductor across which most of the potential difference between the bulk semiconductor and the bulk electrotype should be dropped. A change in the redox potential should then alter the potential gradient within the depletion layer and thus the photovoltage. But if there are electronic states at the semiconductor surface which can be charged and discharged, the potential gradient at the surface will be substantially different from that expected and the interface more like the junction between a metal and an electrolyte. Such surface states may arise from bulk defects in the crystal lattice, from dangling bonds at the surface or by the adsorption of charged species onto the surface. The overall result is a characteristic photovoltage for each junction between a semiconductor and an electrolyte which is independent of the redox couple. It has recently been thought that behaviour of this type is common among small band-gap semiconductors, precisely those which are of most use for solar conversion, p-type silicon in particular. So Fermi pinning and the consequent loss of photoconversion efficiency has been regarded as the last nail in the coffin for liquid-junction photovoltaic devices.

The latest results from the Stanford group are particularly important because they show that device performance is not necessarily limited by the intrinsic properties of the interface between p-Si and the non-aqueous electrolyte. The explanation is not yet clear, but it seems likely that there is an obverse phenomenon to 'Fermi pinning' which might be called 'redox-pinning'. In a photovoltaic device of the type described, both oxidized and reduced forms of the couple would accumulate at the surface. If the components of the redox couple can communicate with the bulk of the semiconductor much faster than the surface states, the filling of these states will be effectively determined by the relative concentrations of the components of the redox couple in solution. And if these vary little with the degree of bias on the semiconductor, then the junction will behave as a classical device.

It now remains to be seen whether these important findings can be translated into a working cell configuration without loss of conversion efficiency. □

Molecular biology

Selfish DNAs with self-restraint

from W.F. Doolittle, T.B.L. Kirkwood and M.A.H. Dempster

TRANSPOSABLE elements are small discrete genetic elements which can be replicated independently of the chromosomes in which they are embedded. Mechanisms of independent replication may vary, but the results are almost always the same — new copies appear at new genomic positions without loss of original copies[1]. Models of how transposition could occur have been with us for some time and now we are beginning to see models of how the process could be regulated.

In a recent issue of *Cell*, Kleckner and her colleagues describe the inwardly and outwardly directed promoters of IS10-Right, one of the two copies of the insertion sequence IS10 which form the terminal repeats of the bacterial transposon *Tn*10 (refs 2,3). Transcription of the IS10-encoded transposase gene initiates at the weak inward promoter pIN. The stronger pOUT is responsible for activation of genes distal to the site of IS10 or *Tn*10 insertion. The two are transcriptionally independent, but active pOUTs inhibit, in *trans*, the expression of transposase genes. This translational inhibition is mediated, Simons and Kleckner[3] suggest, "by direct pairing between the transposase messenger RNA and a small, complementary, regulatory RNA specified by the IS10-encoded pOUT promoter".

This molecular model makes excellent sense of the genetic phenomenon of multicopy inhibition — the suppression of the transposition-related functions of a single *Tn*10 transposon by multiple copies of its IS10 terminal repeats elsewhere in the cell. It also makes evolutionary sense. Transposable elements are viewed by some as

0028-0836/84/060501-02$01.00

© 1984 Macmillan Journals Ltd

molecular parasites[4,5]. Good parasites might wish to be gentle with hosts. (This is, for instance, the textbook explanation for the rapid loss of effectiveness of the myxomatosis virus introduced to control Australian rabbit populations in the 1950s — an attenuated parasite spreads more slowly but more surely through a larger and healthier host population[6].)

The eukaryotic transposable element P, an inhabitant of the *Drosophila* genome, provides another intriguing example of self-restraint at the molecular level[7]. Some 30–50 partial or complete copies are borne by *Drosophila* strains designated P. The mating of P males with females from element-free M strains produces sickly and nearly infertile ('dysgenic') hybrids as a direct result of unrestrained P replication. Hybrids which do survive produce, over several generations, flies of increasing vigour with increasing tolerance to mating with P males. The hybrid stock has itself become P, and is said to have acquired P cytotype.

There are many ways this could be explained but the recent model of O'Hare and Rubin[8] has particular appeal. P encodes, they suppose, a transposase and a regulator of transposition. The latter not only affects transposase activity (or synthesis) negatively, but its own activity (or synthesis) positively. Thus "in a dysgenic cross, P factor DNA is introduced into a background where there is neither transposase nor regulator, and expression of both functions leads (at least initially) to transposition. With time, positive feedback by the regulator of its own level of activity produces enough regulator to shut off transposition and the P cytotype is established".

The evolutionary value of self-restraint in transposable elements seems obvious intuitively, but it is always reassuring to have intuition confirmed by theory. The mathematics can be made fairly simple[9]. If χ is the average copy number of the element per cell, the net rate of multiplication for each cell in a (potentially) exponentially growing host population can be written as an expression in three terms, $\varrho(\chi) = \phi(\chi) - \gamma \, d\chi/dt - \omega$. $\phi(\chi)$ is the rate of cell division, which may be diminished as the element load increases; γ is the probability that each new transposition causes lethal mutation; and ω is the basal level of cell mortality independent of the element load. For an element without any form of restraint, both χ and $d\chi/dt$ will increase exponentially with time and in due course $\varrho(\chi)$ becomes negative. This may be due partly to declining $\phi(\chi)$, but mainly to rapidly increasing $\gamma d\chi/dt$. Once $\varrho(\chi)$ is negative, host cells are dying faster than they are born so the host cell population is driven to extinction and with it the element itself. On the other hand, if the element acquires the trick of restraining its transposition so that its copy number is limited to n, then (provided $\phi(n) > \omega$) the cell multiplication rate remains positive as $d\chi/dt$ goes to zero. The upshot is that, although the element may impose some small loss of fitness on its host, measurable as $\phi(0) - \phi(n)$, both of them continue to exist.

It takes little insight to deduce that, given these two alternatives, the better strategy for the transposon in the long run is to exercize self-restraint. The selection mechanism by which this outcome is reached is not entirely straightforward, however, since the force at work is the comparatively weak evolutionary process of group selection[10]; that is, it is through competition between groups, or clones, of cells containing both types of element that the unrestrained ones are eliminated and the restrained ones arise. Should competition arise within a clone, as would happen if a *Tn*10 pIN mutated to become unresponsive to the inhibitory effect of pOUT, the unrestrained mutant would enjoy a temporary but strong selective advantage until the clone was extinguished. Theory predicts that this type of behaviour should from time to time be observed, and it will be interesting to see if this is the case. □

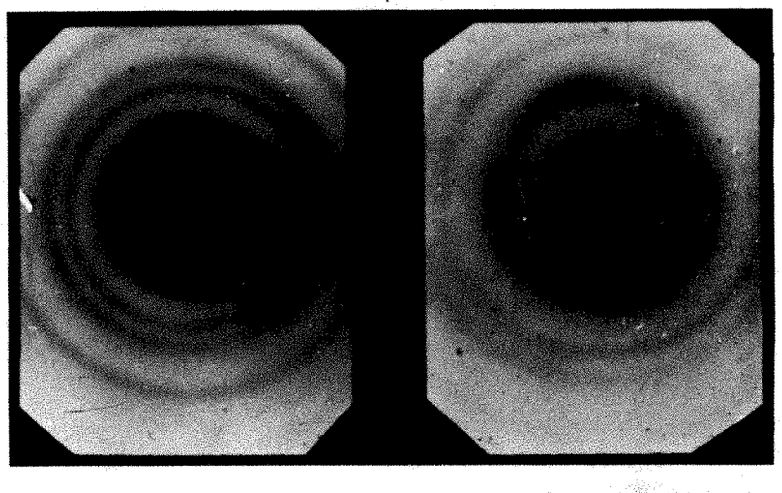
Waves and particles: the diffraction of electrons



LOUIS DE BROGLIE sparked one of the most productive controversies in twentieth-century physics when he suggested that a frequency could be associated with a fundamental particle of matter as though it consisted of a group of waves. Could wave-particle duality be experimentally demonstrated?

Two independent experiments performed in 1927 implied that it could: the first, a study by Clinton Davisson and Lester Germer, of the scattering of a narrow beam of electrons off a nickel crystal; the second, by George Paget Thomson, of the diffraction of electrons transmitted through thin films. Their respective detectors were a galvanometer and a photographic plate. In Thomson's first experiment, electrons from a cathode-ray tube traversed an extremely thin film of celluloid 10 cm in front of the photographic emulsion, the whole apparatus being evacuated to avoid attenuation of the electron beam by air molecules. A pattern of concentric rings certainly appeared, but the argument for electron diffraction was not quite watertight since the atomic structure of cellulose was not yet accurately known.

Gold foil was substituted to provide a crystalline lattice of known structure, and shown here are the photographs which Thomson initially obtained (October 1927 at the University of Aberdeen). Larger rings (right) are associated with lower energies, as measured by the spark gap of the induction coil. The patterns, wrote Thomson later, "at once gave rings which agreed quantitatively with the theoretical expectation for a face-centred cubic lattice of side 4.06 Å". He concluded that the detailed agreement between his studies of electron diffraction and the de Broglie theory "must, I think, be regarded as strong evidence in its favour".

The photograph is reproduced by courtesy of the Science Museum (Natural History), where Sir George Thomson's original apparatus is also displayed. □

Gene expression

DNA methylation — how important in gene control?

from Adrian P. Bird

Is DNA methylation a key element in the regulation of vertebrate gene expression, or does it play a minor part? There is support for both views in the recent literature, for while it is now clear that *in vitro* methylation inhibits the transcription of several genes (see *News and Views* **296,** 602; 1982)[1], some *in vivo* studies raise doubts that reduced methylation is always a necessary precondition for gene expression.

Experiments with mouse retroviruses have provided strong evidence that DNA methylation can suppress transcription. Integrated viral sequences that are endogenous to mice are non-infectious and heavily methylated. This natural situation can be mimicked by introducing unmethylated proviral DNA into preimplantation embryos or embryonal carcinoma cells[2]. No infection results, and the surviving integrated copies of the provirus are found to be heavily methylated. Purified DNA from each of these sources is non-infectious, but infectivity can be restored by treating the cells with 5-azacytidine, an inhibitor of methylation, or by recovering the integrated provirus after cloning in bacteria[2–4]. Since molecular cloning causes loss of methylation at CpG sequences — the major site of methylation in animals — it seems likely that lack of infectivity is caused by methylation.

Confirmation is provided by the observation that remethylating the cloned proviral DNA with a rat liver methyltransferase abolishes infectivity once more[5]. As well as rounding off the experimental logic, these studies make the important point that methylation is inhibitory only at certain CpGs, as methylation of a subset of CpGs with the *Hpa*II methylase does not inhibit infection. Since *Hpa*II is commonly used to analyse methylation of genomic sequences, it is salutary that, in this case, *Hpa*II sites alone were not relevant to expression.

Experiments by Busslinger *et al.*[6] also stress the importance of specific CpG sequences. Members of the human β-globin gene family were methylated at CpG by using the ingenious method pioneered by Stein and co-workers[7]. The globin gene is cloned in a single-stranded M13 vector and a second strand is synthesized in which all cytosine residues are methylated. Upon transformation of this DNA into mouse cells, cellular methyltransferases can act on the unmethylated strand only at CpG. Thus when the transformed clone grows, the methylation at CpG sequences is maintained while methylation at cytosine residues in other sequences is lost. The initial experiments showed that cells which have been transfected with both a methylated γ-globin gene (which becomes methylated at all its CpG sequences) and an unmethylated β-globin gene (which remains unmethylated) were able to express the β-globin gene but not the γ gene. Thus methylation appears to be inhibiting transcription.

To extend this result, Busslinger *et al.* synthesized molecules in which certain segments were protected from methylation. When regions upstream of the 5′ end were left unmethylated, but the transcribed region was methylated, transcription of the γ-globin gene was seen. But when this pattern of methylation was reversed, so that the 5′ flanking regions were methylated, transcription was abolished. These and other experiments establish that somewhere between 760 base pairs (bp) upstream and 100 bp downstream of the 5′ end of the γ-globin gene are one or more CpG sequences whose methylation prevents transcription in mouse cells. Methylation at CpG sequences elsewhere is apparently irrelevant to transcription in these cells.

Of course, in order to be sure that loss of methylation is really part of globin gene activation *in vivo*, it is necessary to find out whether the relevant CpG sites are ever methylated in cells which do not synthesize globin. This is particularly important given that the hamster adenosine phosphoribosyl transferase gene is inhibited *in vitro* by methylation[8], but has recently been discovered to be unmethylated at the relevant sites in most, if not all, tissues[9]. Consistently unmethylated domains, regardless of expression, have also been observed at the 5′ end of the mouse dihydrofolate reductase gene[9] and the chicken α2(I) collagen gene[10], suggesting that changing levels of methylation are not a component of regulation for these genes either.

The existence of genes with what may be constitutively unmethylated 5′ domains does not contradict the idea that DNA methylation interferes with transcription, but merely emphasizes that absence of methylation is not sufficient to ensure transcription. There is, however, a case where heavy methylation of a purified gene appears to have no effect on transcription[11]. At the time in embryogenesis when the genes neighbouring them become active, ribosomal RNA genes (rDNA) of *Xenopus laevis* lose CpG methylation at certain spacer sequences. In sperm rDNA, though, the CpG sequences of the spacer region, including all 19 sites in the promoter, are highly methylated. Even so, sperm rDNA is transcribed just as efficiently as cloned (that is, unmethylated) rDNA upon injection into the nuclei of *Xenopus* oocytes; and transcription does not seem to be due to loss of methylation following injection. By contrast, methylation of two viral genes inhibits their transcription in the oocyte[12,13]. Although rDNA may not qualify as a typical vertebrate gene, methylation and transcription clearly are not always inimical.

Other exceptional genes have been hinted at by experiments in which methyl-sensitive restriction endonucleases were used to follow hormonally induced changes in gene expression. In the case of the chicken vitellogenin gene, transcription after treatment with oestrogen is associated with loss of methylation at a CCGG site about 600 bp upstream of the 5′ end[14–17]. Other sites in the vicinity of the gene remain methylated regardless of transcription. What is surprising, though, is that loss of methylation at this *Hpa*II site is gradual and follows, rather than precedes, the peak of vitellogenin gene transcription. Moreover, the same *Hpa*II site is gradually demethylated in oviduct, a tissue that does not transcribe the vitellogenin gene. In another species, *X. laevis,* all 20 testable CpG sequences at the A2 vitellogenin gene are as highly methylated in hormone-stimulated liver as in unstimulated liver and blood cells[18].

On the face of it these findings seem to violate the conventional view that undermethylation is a necessary precondition for transcription. There is, however, an acknowledged weakness in this kind of experiment — only a minority of CpG sequences are within a sequence that can be recognized by one of the methyl-sensitive restriction endonucleases. Thus failure to find a correlation between expression and methylation may arise simply because the

endonucleases do not detect the relevant sites.

How can the inherent weaknesses of the restriction enzyme approach be overcome? The answer may lie with an unlikely-sounding, but recently perfected, technique for sequencing unique stretches of DNA in unfractionated genomic DNA. George Church of Harvard University has used a sophisticated blend of blot hybridization and Maxam–Gilbert[19] sequencing to locate all 5-methylcytosine residues in a region of the globin gene of transformed mouse cells (see ref. 4). It would now be interesting to use this technique to monitor other CpG sequences during activation of the vitellogenin genes.

In evaluating recent data on gene expression and DNA methylation, it may be helpful to take an evolutionary perspective, starting from the observation that the level of CpG methylation is considerably higher in vertebrates than in invertebrates. Apart from the much quoted case of *Drosophila*, in which methylated cytosine residues have not been detected at all[20], other invertebrates generally have a minor fraction of heavily methylated DNA in their genome[21]. No clear example of a methylated gene has yet been detected in invertebrates. Since these animals nevertheless exhibit cellular determination and differentiation, it seems likely that, in animals, DNA methylation was not involved in the evolution of these basic mechanisms.

Why, then, are the majority of vertebrate genes methylated? One possibility is that DNA methylation in invertebrates has a purely suppressive effect — simply being used to condemn sequences to transcriptional silence — while in vertebrates, the spread of methylation has elicited mechanisms that allow genes to tolerate and, in some cases, to exploit methylation for the control of expression.

There are three ways in which a gene might circumvent suppression by DNA methylation. First, key sequences might be maintained in an unmethylated condition by rendering them refractory to methylation, as in the case of genes whose 5′ domains are unmethylated in expressing and non-expressing tissues alike[8,9]. Second, genes may tolerate methylated bases at their regulatory sequences, as the ribosomal RNA genes of *Xenopus* appear to do. Last, expression of the gene may be suppressed by methylation in inappropriate tissues, but in tissues where the gene is to be expressed transcription can proceed following demethylation. It is this role for methylation that has hitherto attracted most interest, and it is to this category that the globin genes may belong.

A demethylation step is usually envisaged as a pre-requiste for transcription of genes regulated by loss of DNA methylation. A weakness of this view is that to regulate genes separately, a distinct mechanism is required to demethylate each kind of gene — it is difficult to see why this should have evolved. An alternative control mechanism, and one whose evolution is perhaps easier to envisage as an ancestral gene moved from the unmethylated to the methylated condition, is that activation of the gene begins with the gene still in a methylated state. Activation then leads to demethylation which, in turn, relaxes control of the gene. Here, demethylation is not thought of as a mechanism to facilitate initial activation of the gene, but to simplify continued expression once activation has occurred, perhaps by bringing the gene under more 'everyday' control mechanisms.

Although we do not yet know how any eukaryotic gene is regulated, preliminary evidence suggests that the degree of involvement of DNA methylation is variable. This is consistent with the view that methylation of genes was a relatively late occurrence in animal evolution, and it suggests that we should not expect a coherent unified mechanism for control of gene expression based on DNA methylation. In order to learn just how much of gene control is due to modulation of DNA methylation patterns, we must await future studies on a gene-by-gene basis. □

Biotechnology

Time for plant cell culture?

from M. W. Fowler

WITH the announcement last year by Mitsui Petrochemical Industries of a process for the production of the pharmaceutical and dye shikonin by large-scale plant cell culture, plant cell biotechnology at last became a reality on the industrial scene. Although the scale of activity (some 750 litres bioreactor capacity) is small in comparison with large-scale microbial fermentation processes, the shikonin process nonetheless marks an important first step forwards in plant cell biotechnology. Hitherto this area of biotechnology had been considered by many to be 'just another way of looking at plant biochemistry' rather than as a genuine alternative way of manufacturing plant natural products.

Plant cell culture may prove of particular value in the future in situations where a new chemical structure with interesting properties has been identified but the source plant is particularly difficult to grow. Of course, the possibility of deriving the compound by organic synthesis must be considered first — but there again there are now several reports of the synthesis by cell cultures of chemical structures that are quite unique. Before cell culture sets off in new directions, however, the technology must first be proved on an existing product.

In Japan, the Japanese Salt and Tobacco Monopoly has made particular progress towards the development of a tobacco biomass system and has used conventional stirred tank bioreactors (fermenters) at volumes in excess of 6,000 litres. Pharmaceuticals have been the target in West German laboratories and substantial success has been achieved at the University of Tübingen in the development of a process for the biotransformation of low-value digitoxin to the important and high-value cardiatonic digoxin.

Plant cell cultures are maintained in liquid culture in much the same way as yeasts and other microbial cells, but there are some major differences: plant cells grow much more slowly than microbial cells and doubling times of the order of 20–150 h are typical. Sub-culture periods are thus much longer. Also, it is easy to maintain microbial species in a culture bank, either lyophilized or cryopreserved, but similar techniques are only just being developed for plant cell cultures. In consequence, large liquid culture banks are needed to support plant cell cultures. Even if cell preservation techniques do become viable, the long time required to grow up plant cell cultures still means that careful planning is essential to initiate large-scale cultures.

On present-day costings, plant cell culture is likely to be considered only for high-value low-market-volume products. In general, products have to have a whole sale value of at least $250-500 per kg to make them worth considering as targets for a cell culture process. Once one or two processes have been developed successfully, however, the increased know-how and confidence are likely to lead to a widening of the target window.

What are likely to be the key developments in the years ahead? The comparatively few large-scale systems that are being actively tested have not encountered major problems. Fairly sophisticated technologies such as fluidized bed and immobilized cell systems are also showing rapid development. One area which is in urgent need of consideration is downstream processing, the unglamorous but often highly expensive end of the business. It is back in the cell however that the biggest problems still face us. Lack of the fundamental biochemical and genetic information that would enable control of product yields is the chief constraint on the development of plant cell biotechnology and there is much fundamental research that needs to be done. □

Deep seismicity and modes of deformation in Tonga subduction zone

Domenico Giardini & John H. Woodhouse

Department of Geological Sciences, Harvard University, Cambridge, Massachusetts 02138, USA

The geometry of deep (>400 km) earthquakes in the subducting western edge of the Pacific plate, when related to the local distribution of seismic activity, reveals a complex pattern of planes of shear failure, enabling the modes of deformation by which the descending plate shortens and thickens to be identified. The deepest part of the slab is displaced laterally, suggesting that it fails to penetrate the discontinuity at 670 km.

DEEP earthquakes occur in steeply dipping zones—Benioff zones—which, with the advent of plate tectonics, have been recognized as the trajectories of oceanic lithosphere subducted deep into the Earth's mantle[1]. Although most Benioff zones terminate at shallower depths, there is an absolute cutoff in activity at 650–700 km, and this has often been taken as *prima facie* evidence that subduction does not penetrate into the lower mantle. It is possible, however, that the cessation of seismic activity corresponds to the point in pressure–temperature space where catastrophic failure ceases to be a possible mechanism of deformation, in which case no inference can be drawn concerning the subduction of material to greater depths[2,3]. The question of whether or not subduction continues into the lower mantle is of great importance for our understanding of mantle convection and for models of the chemical evolution of the Earth because of its bearing on the question of whether the upper and lower parts of the mantle are isolated, separately convecting systems, or whether they are parts of a single, mantle-wide and chemically mixed convective flow[4–7]. For this reason we have studied the seismicity in one of the deepest and most active Benioff zones—the Tonga Arc—to obtain information concerning the deformation of material at great depth.

There has been much research related to the possible mechanisms of deep earthquakes. It has long been recognized that under conditions of temperature and pressure appropriate to the mantle, brittle failure is an unlikely mechanism for deep earthquakes and other mechanisms by which shear failure can occur have been put forward[8–11]. The occurrence of sudden phase transformations in the subducting lithosphere has been considered as a possible mechanism[12–15], or as a triggering mechanism[16], for deep events; the seismic evidence, however, favours a mechanism dominated by shear failure, as is the case for shallow earthquakes[17–19].

From seismic radiation it is possible to identify a pair of orthogonal planes at the focus—the nodal planes—which are the possible planes of shear failure. Extensive studies have revealed that the orientation of these planes is indicative of systematic shortening or extension in the down-dip direction[17,20]. However, the existence in deep Benioff zones of persistent planes of failure, or faults, has been an open question. Such planes may be expected to manifest themselves as lineations in the spatial distribution of hypocentres, but evidence of this kind has been obtained for only a few events[21–24].

In the Benioff zone associated with the Tonga trench, earthquakes almost invariably indicate down-dip shortening. We have determined[25–27] the moment tensors of 49 events in Tonga at depths >400 km, using the 'centroid-moment tensor' (CMT) technique of Dziewonski *et al.*[28]. This technique uses digitally recorded waveforms from the Global Digital Seismograph Network (GDSN) including all body wave phases; this enables us to obtain reliable results for the moment and the geometry of seismic sources using, in some cases, as few as six stations. An adequate digital data set has been available only since 1977 and the 49 CMT events constitute all earthquakes in Tonga deeper than 400 km large enough for the CMT technique to be applied.

Fig. 1 Map view of the south-west Pacific showing earthquakes with body wave magnitude $m_b > 4$ from the ISC catalogue 1964–79. All the events in the Tonga Benioff zone deeper than 300 km have been relocated using the technique of joint hypocentre determination.

To obtain an accurate representation of the seismic activity in the neighbourhood of each CMT event we have relocated some 2,200 events, deeper than 300 km, using P-arrival times reported by the International Seismological Centre (ISC, 1964–1979). Relocation was performed using the technique of joint hypocenter determination[29,30] (JHD). Estimates of the reliability of each hypocentre were obtained, and events having poorly determined coordinates were rejected.

One of our principal observational findings is that for more than 40 of the 49 CMT events it is possible to identify planar alignments in the pattern of relocated hypocentres in

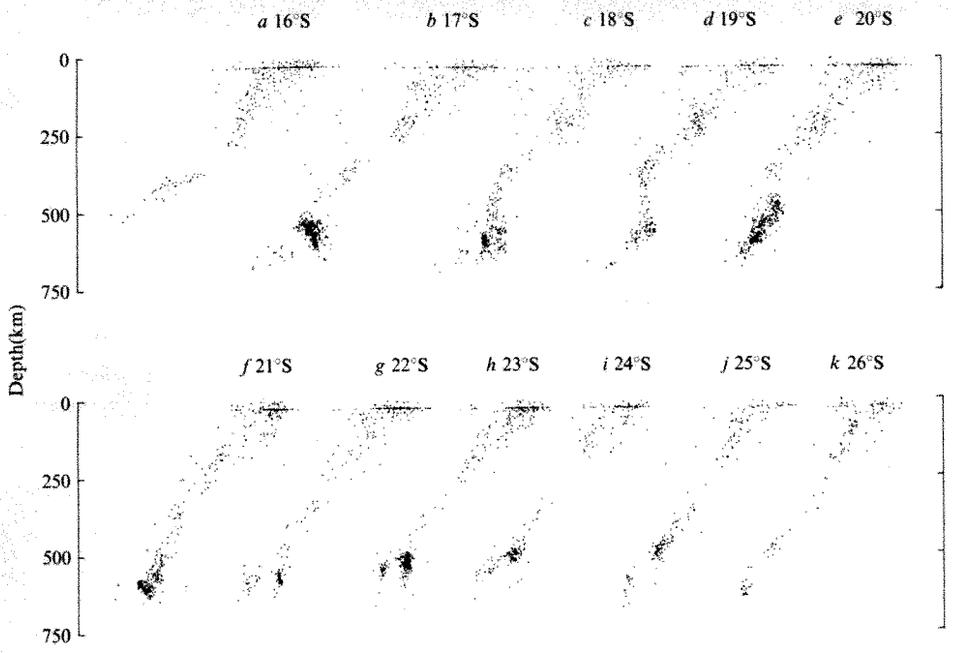

Fig. 2 Vertical sections through the Tonga Benioff zone between 16 and 27° S. The sections are along parallels of latitude, viewed from the south. Each is 1° thick and includes seismicity to the south of the indicated parallel.

approximate agreement with one, or occasionally both of the nodal planes; from this we infer the existence of planes of shear failure. The complex pattern of shear zones identified by this technique enables us to begin to elucidate the structural geology of the subduction zone.

Morphology

The Tonga and New Hebrides subduction zones form a highly complex part of the Melanesian boundary between the Indian–Australian plate and the Pacific plate (Fig. 1). The Benioff zone studied here is associated with the subduction of the Pacific plate to the west beneath the Indian–Australian plate and both the characteristics of the seismicity[31–35] and the nature of stress release in the subducting slab[6,17,35–37] have been studied. The inclined seismic zone terminates in the characteristic 'hook' shaped region of intense deep activity. All of the CMT events analysed in this study are located within this 'hook' (Fig. 4).

Figure 2 shows a sequence of vertical sections through the Benioff zone, having a thickness of 1° in latitude. Notable here is the extreme distortion and variable geometry of the zone. The separation of the seismicity into double seismic features, at great depth, is evident in several sections (Figs 1, 2*b*, *c*, *g*–*j*). Figure 3 shows a projection onto a vertical meridional plane, looking from the west, and displays some aspects of the vertical distribution of events.

For our later discussion we identify four principal regions within the zone of deep activity (see Fig. 3):

The northern region (17°–19° S): Intense seismic activity at the northern end of the 'hook' forms an inclined column. Its vertical extent can be seen in Fig. 3. A weak secondary line of activity flanks the region to the south-west (Fig. 1).

The central region (19°–21.5° S): This is a region of diffuse seismicity dipping at a shallower angle than other parts of the deep seismic zone (Figs 2*d*–*f*, 3).

The southern region (21.5°–27° S): This region is characterized by two parallel bands of seismicity (Fig. 1). The weaker band lies to the west and penetrates to greater depths, particularly in the south (Fig. 2*g*–*k*).

The gap (22.3°–23.2° S): The principal band of deep seismicity is interrupted by a distinct gap (Figs 1, 3). This gap appears to correspond with the gap in shallow activity (Fig. 1) which separates the Tonga and Kermadec Trenches, and coincides with the intersection of the Louisville Ridge with the trench at ~25° S.

Moment tensor solutions

We shall discuss here a set of 17 moment tensor solutions and their implications for deformation within the subduction zone. Many of these are representative of families of solutions showing the same behaviour. The moment tensor is a second rank symmetric tensor, which may be characterized in terms of its principal axes and its eigenvalues. The moment tensors determined in this study are constrained to have zero trace, corresponding to a source without volume change, and thus the sum of the eigenvalues is zero. A positive eigenvalue represents extension at the source and a negative eigenvalue corresponds to shortening. The largest eigenvalue is positive and is associated with the tension axis (T-axis) and the smallest eigenvalue is negative and is associated with the compression axis (P-axis). The intermediate eigenvalue is smallest in absolute value. In agreement with previous studies[6,17,35] we find that in Tonga the P-axis is usually in the down-dip direction, indicating net shortening of the zone. This can be seen in Fig. 4, where the P-axis is indicated by '+'. The moment tensor solutions are represented here in terms of an equal area projection of the lower focal hemisphere. The intermediate axis is at the intersection of black and white quadrants.

A source represented by a shear dislocation has a vanishing intermediate eigenvalue and P and T eigenvalues of equal magnitude, with opposite signs. Such a source is said to have a 'double couple' mechanism. We find that in Tonga the compressive eigenvalue tends to be the largest in absolute value (though other subduction zones exhibit different behaviour[26,38]). Here, however, we shall neglect this departure from the condition for plane shear failure, and concentrate on the geometry of the 'best double couple' solution.

The planes separating black from white in Fig. 4 are orthogonal nodal planes, which intersect in the intermediate axis and are inclined at 45° to the other two axes. The best double couple solution may be interpreted in terms of shear failure on either of these planes, in which relative motion is perpendicular to the intermediate axis and is in the sense which would take a material particle from a white into a black quadrant.

In Fig. 5 we have taken, as the centre of our field of view, events for which CMT solutions have been found, and displayed the local pattern of seismicity as seen from the direction of the intermediate axis. From this direction any lineations in the pattern of seismicity associated with planes of shear failure should be apparent, and should be aligned with one of the nodal

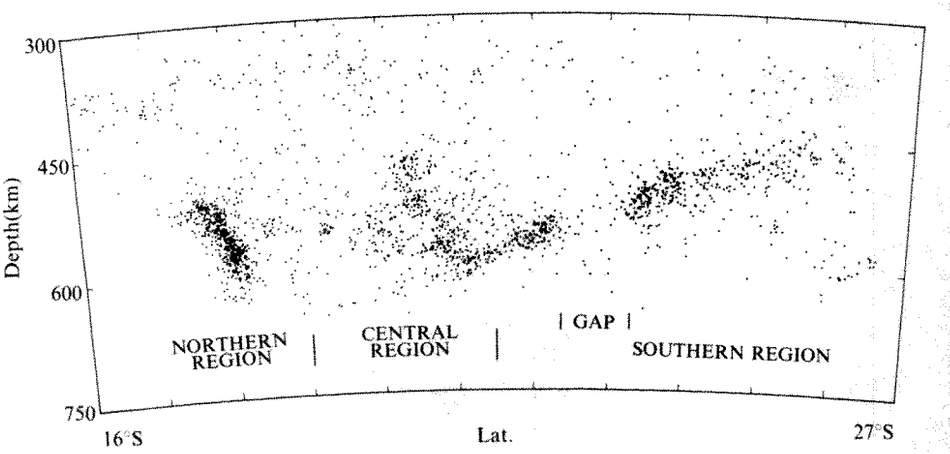

Fig. 3 Lateral projection of the seismicity on a vertical meridional plane viewed from the west. The subdivisions correspond to subregions of the Benioff zone identified in the text.

planes. We find that such lineations are nearly always discernible in the seismicity patterns of the relocated events, and we interpret these lineations as zones of shear failure. Viewed from the direction of the intermediate axis the nodal planes appear as straight lines which divide the circle into quadrants. The direction of maximum shortening (the P-axis) lies in the white quadrants and the T-axis lies in the blackened quadrants. These are orthogonal and are inclined at 45° to the nodal planes.

In each part of Fig. 5 the latitude, longitude and moment of the event are indicated, together with the direction of view and the scale of the box. Figure 5*a*, for instance, is centred on an event of 21 January 1977 (moment, 10^{25} dyn-cm), viewed from an azimuth of 158°, with the line of sight inclined slightly upwards, at an angle of 3° to the horizontal. The sides of the box are of length 300 km and the depth of the box in the direction of the line of sight is 160 km. A set of criteria on size, reliability of location, and azimuthal coverage of stations has been specified in each part of Fig. 5 to clarify the feature which we believe to be associated with the CMT event. In a few cases it has proved difficult to separate such features from the background seismicity which presumably is indicative of other modes of deformation; in such cases the time sequence of events has often convinced us of the reality of the lineation.

Northern region

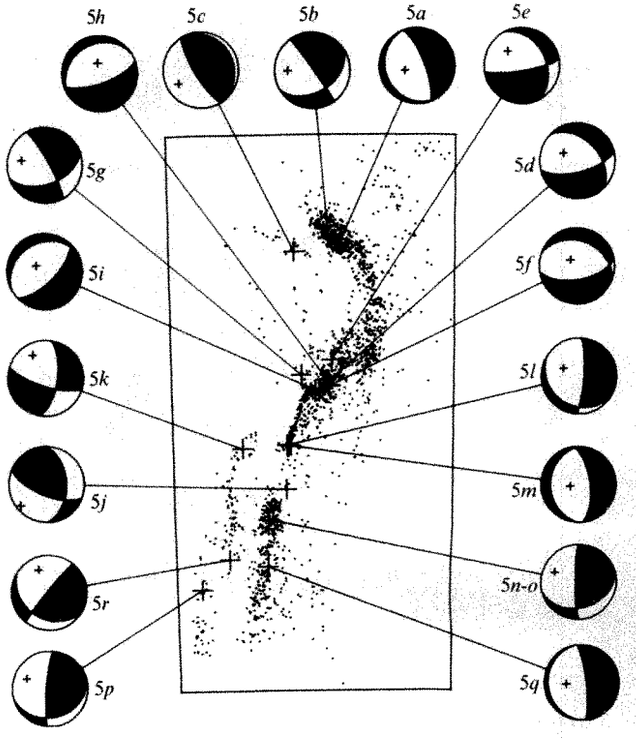
Figure 5*a–c* shows events located in the northern region (Figs 3, 4). In Fig. 5*a* we would identify the approximately vertical lineation as a plane of shear failure. Figure 5*b* shows the same cluster of events seen from a steep angle. The events on the right in Fig. 5*c* are coincident with some of the events of Fig. 5*a*, but here the CMT event lies in the weak secondary zone of seismicity lying to the south-west (Fig. 4). In this case there are rather few events to define the lineation; the pattern is very similar, however, to the patterns observed in southern Tonga to be discussed below (Fig. 5*l–r*).

Central region

CMT events in the central region (Figs 3, 4) may be classified into two distinct families. Figure 5*d–f* shows representatives of the first family, and indicates a shearing deformation approximately in the plane of the Benioff zone. The second family (Fig. 5*h, i*) shows out-of-plane shear. Events in the first family (Fig. 5*d–f*) all show motion in the same sense within three subhorizontal lineations, gently dipping to the north and located at different depths (event in Fig. 5*f* is located in the lowermost lineation). This indicates a mode of deformation of subhorizontal shearing of the zone. A cross-cutting conjugate lineation is also apparent (Fig. 5*d*). The events of Fig. 5*f, g* show motion on different planes which are internal to the lowermost shear zone and are indicative of an organized internal structure. Events of the second family are shown in Fig. 5*h, i*. A complex structure of subhorizontal planes dipping at ~30° to the north-west becomes apparent.

We infer that in this central zone there are simultaneously active modes of shear deformation both in and out of the plane of the Benioff zone. Both the moment tensor solutions and the seismicity patterns indicate thickening and bottoming out of the descending material, and suggest that subduction experiences great resistance in penetrating the 670-km discontinuity.

As we have noted above, the gap in shallow seismicity which separates the Tonga subduction zone from the Kermadec zone is associated with the intersection of the Louisville Ridge with the trench and this gap appears to correspond to the gap in deep seismicity (Figs 1, 3). If, however, the ridge were embedded in a rigid subducting slab it would intersect the deep seismic activity much farther to the north. It is possible to identify the gap in deep activity with the Louisville Ridge if the entire zone



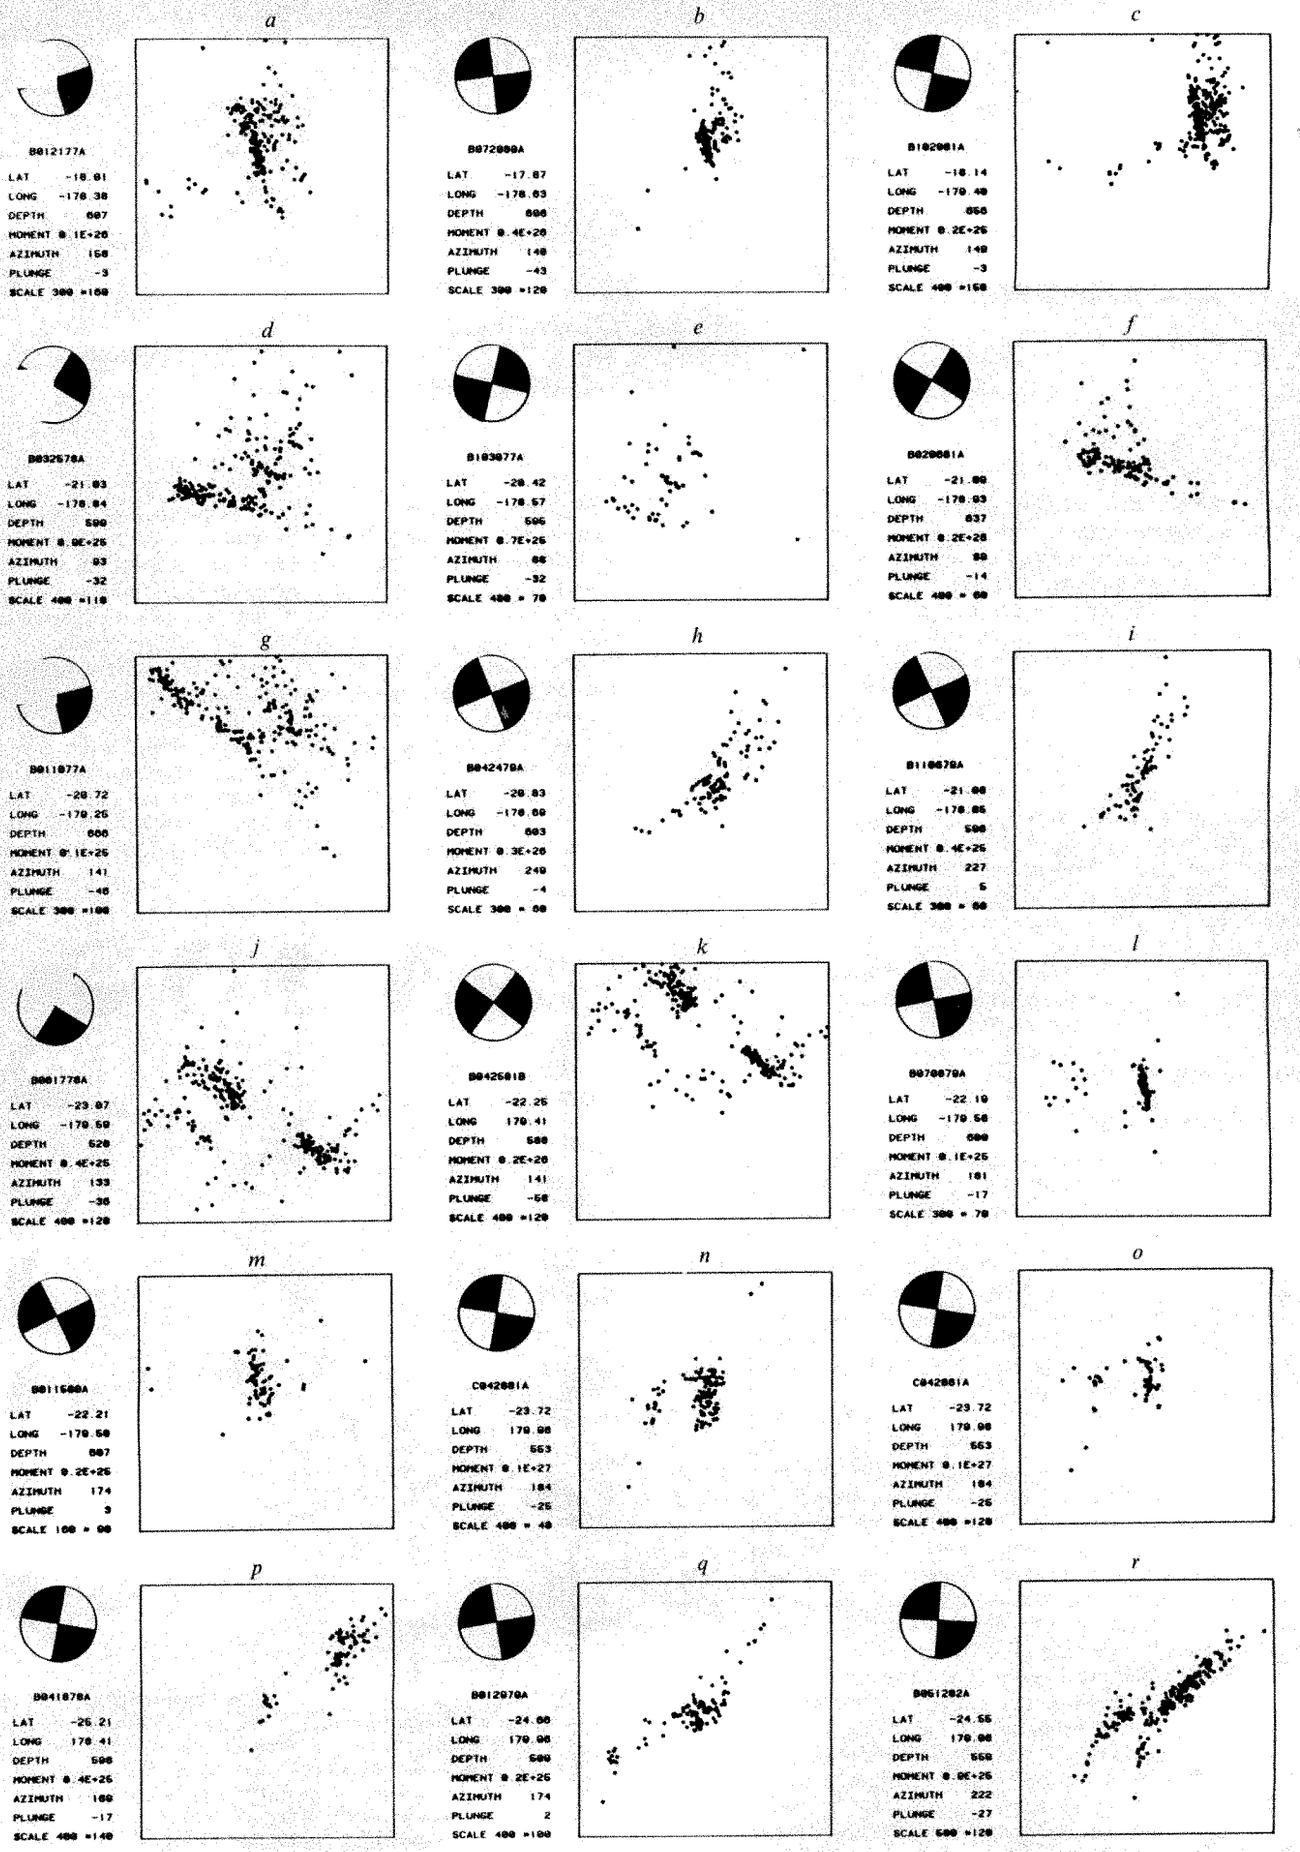


Fig. 4 Focal mechanisms of the selected CMT solutions. For each event the equal area projection of the lower focal hemisphere is shown, viewed from above; '+' represents the compressional axis and the black sectors indicate extension at the source. Relocated seismicity is plotted, deeper than 300 km and with latitude between 27 and 16° S and longitude between 178° E and 176° W. Each CMT event is identified by a number corresponding to events detailed in Fig. 5.

has suffered horizontal shearing in which deeper material moves relatively south. This is the same sense as the shear inferred from Fig. 5*d–f*.

The gap

Figure 5*j, k* shows two events associated with the gap in deep activity. These are anomalous in that they do not show down-dip shortening and are of opposite sense. We note, however, that they are on opposite sides of the gap, and are both consistent with motion of the material in the gap, approximately in the down-dip direction, at a faster rate than the surrounding material.

Southern region

Figure 5*l–r* shows events in the southern region, both to the north (Fig. 5*l, m*) and to the south (Fig. 5*n–r*) of the gap. The almost vertical lineation is very clear in Fig. 5*l*; this lineation indicates a backward bending of the deepest part of the descending flow (see Fig. 2*g*). Figure 5*m* shows another event in the same cluster; the enlarged scale reveals a pattern of approximately conjugate alignments.

Figure 5*n–r* shows events associated with the double seismic feature in the south. Figure 5*n, o* shows the same event; in Fig. 5*n* a very thin slice has been taken and in Fig. 5*o* only larger events are shown. The seismic zone is very narrow for large events and the more diffuse pattern of Fig. 5*n* appears to be associated with the occurrence of smaller events on conjugate planes (see Fig. 2*g, h*). The vertical alignments in Fig. 5*n–o, r* indicate shear deformation in which material to the east moves relatively down. The event shown in Fig. 5*p* is in the secondary region of seismicity and shows motion in the same sense. The separated double seismic zone is interrupted by a connecting 'bridge' of seismicity at ~25° S (see Fig. 2*i*). Figure 5*q* shows an event located in this 'bridge', and here both horizontal and vertical alignments can be seen. The pattern of parallel, subvertical shear zones in which the sense of motion is such that trenchward material moves relatively down is reproduced by other solutions not presented here. Similar behaviour in the northern region has been noted above (Fig. 5*a–c*).

Figure 5*r*, which we interpret as shear on the central vertical plane, also shows this behaviour and appears to present us with a snapshot of the slab breaking and being displaced sideways as it reaches the bottom of its trajectory. The double seismic feature at the base of the Tonga subduction zone would represent, in this case, the debris of slab unable to penetrate deeper into the mantle.

Discussion

The correlations we have shown between the orientation of the nodal planes of deep earthquakes and the local pattern of seismicity can be found only if the nodal plane is known very precisely. Accurate hypocentral locations are also necessary, but in fact all of the features we have shown are identifiable using published ISC coordinates; the relocation of events serves principally to bring the patterns into better focus.

This analysis enables us to understand the apparently accidental orientations of the nodal planes in terms of fairly well defined modes of deformation—vertical shear in the northern and southern regions, and subhorizontal shear in the more diffuse central region. In each case shortening occurs in the down-dip direction and material is displaced laterally.

The concept of a subduction zone as a smoothly bending, coherent slab, possessing a uniform thickness defined by the seismicity is in need of modification. When seismicity is analysed in detail, we see a complex, cross-cutting pattern of interacting 'shear bands', and we are led, rather, to view the Benioff zone as that part of the convective flow which, by virtue of temperature, composition and strain rate accomplishes its deformation through episodes of shear instability. Viewed on a time scale of several million years the zone would appear to deform smoothly—and perhaps to no lesser extent than the surrounding mantle.

If, over geological time, the nodal planes were randomly oriented with respect to the P-axis, the result would be thickening and shortening without distortion. If, on the other hand, certain orientations remain dominant over long periods, they may lead to distortion and separation of parts of the slab such as we see in Tonga.

The transition to horizontal shear or to lateral separation in the deepest part of the seismic zone is evidence of the strong resistance experienced by the subducted material to penetration of the 670 km discontinuity. We observe horizontal displacement of the seismically active portion of the slab, and infer that material moves laterally rather than vertically at the base of the deep seismic zone. This favours the view that subduction does not continue into the lower mantle, although we clearly cannot infer the fate of the subducted material after it ceases to be seismically active.

We thank Adam M. Dziewonski for discussions, and for providing us with the ISC data sets. We also acknowledge his very large contribution to the development and implementation of the CMT technique, and the free use we have made of a number of computer programs. We also thank Jim Dewey for his computer program for joint hypocenter determination, Richard O'Connell and Brad Hager for discussions and constructive criticism, and Peter Molnar for his valuable comments. This research was supported by NSF grants EAR82-13330 and EAR83-07603.

Fig. 5 (Opposite) Each part shows the CMT solution and the associated seismicity viewed from the direction of the intermediate axis; the CMT event is located in the centre of the box. The hypocentral position and the scalar moment are indicated for each solution. The azimuth and plunge identify the direction of the intermediate axis. The scale indicates the lateral dimension and thickness of the box of plotted seismicity, both in km. The nodal planes appear as perpendicular lines which divide the focal hemisphere into quadrants of compression (white) and extension (black) at the source. The compressional axis is located in the white quadrants, at 45° to the nodal planes. Only relocated seismicity is shown.

Nd–Sr isotopic composition of granulites and constraints on the evolution of the lower continental crust

Dalila Ben Othman, Mireille Polvé & Claude J. Allègre

Laboratoire de Géochimie et Cosmochimie (LA 196), Institut de Physique du Globe et Département des Sciences de la Terre, Universités de Paris VI et VII, 4 Place Jussieu, 75230 Paris Cedex 05, France

In a statistical study of granulite facies rocks, we have analysed 32 samples with ages ranging from 2,900 to 200 Myr for Sm, Nd, Rb and Sr and $^{143}Nd/^{144}Nd$ and $^{87}Sr/^{86}Sr$ ratios. The Sm/Nd ratio is found to be constant compared with the highly variable Rb/Sr ratio. Using the model age formalism, we show that, in many cases internal differentiation of continental crust follows external differentiation with a large time interval.

SEISMIC studies of the continental crust show that the lower continental crust has quite specific physical properties. From geological observations and studies of drilled samples it has been established that the upper continental crust is composed of sedimentary rocks which overlie a basement mainly composed of metamorphic and granitic rocks. The nature of the lower crust is more controversial. The seismic velocities of lower crustal levels (ranging from 6.6 to 7.2 km s^{-1})[1] correspond to those measured for metamorphic and igneous rocks equilibrated in the granulite facies. Indeed, high pressure experiments show that such metamorphic assemblages are generated in pressure–temperature conditions similar to those prevailing in the lower continental crust. These observations have led several authors (for example refs 2–9) to abandon the old concept of a lower basaltic crust and to consider a lower crust mainly composed of granulites (in the sense of granulite facies rocks). Such granulites are mixtures of meta-sedimentary and meta-igneous (acid and basic) rocks, both metamorphosed in the same (high P, high T) conditions.

Heat flow interpretations in continental environments and direct measurements of U, Th and K concentrations in granulites have led several authors[10–13] following Heier[4] to postulate that the lower crust is depleted in U, Th, K and Rb. Such a depletion would explain the enrichment of the upper crust in these elements. According to these authors, this depletion would result from a general differentiation into an upper and a lower level within the continental crust in association with crustal anatexis and/or fluid migration; this would represent a fundamental process of continental crust evolution.

Thus, when considering the formation and development of the continental crust one must distinguish two potentially distinct geological processes: first the process by which a piece of new continental crust differentiates at the expense of the mantle (referred to as external differentiation of continental crust or EXCOD) and second, the process by which the upper and lower levels differentiate within the continental crust (referred to as internal differentiation of the continental crust or INCOD). What are the exact relationships between EXCOD and INCOD? Do they occur simultaneously or independently in time? What are their relationships with the orogenic processes? Are the answers to those questions unique? Any contribution to these problems may be critical to solving our understanding of the development of the continental crust.

Recently[14], the genesis of upper continental crust was investigated on a large scale through the study of granitoid rocks of different ages, using the coupled Sr and Nd isotopic tracers. The main result of this statistical study was that, in general, the Precambrian granitoids have a signature relatively close to that of the mantle whereas clear evidence was found for recycling processes being involved in the genesis of young granitoids. Although this approach was based on a limited number of samples, it has been confirmed by several case studies of granitoid rocks throughout the world: western US[15,16], Caledonian[17] and Hercynian[18] granites in Europe, Namibian of Africa[19], Western Australia[20]. The genesis of old granitoids is not so simple because the Nd[21] and Sr isotopic growth curves of the Archaean mantle are still debated and because lead isotope studies suggest that the genesis of old granitoids is similar to that of young ones[22].

Using a similar approach for the lower continental crust, the present study surveys various types of granulites of different geological ages. It will be followed by some detailed case studies.

The study of granulites is more complex than that of granitoids because they are not direct igneous products with a well defined age of intrusion. They rather frequently correspond to polymetamorphic assemblages with quite complex tectonometamorphic histories; some were originally igneous rocks, some others were sediments, as testified by the presence of abundant marbles in granulitic formations. Therefore isotopic results in granulite terranes generally require detailed discussion, integrating geological constraints.

In a strict petrological sense, granulite facies rocks correspond to regional high grade metamorphism with rare hydrous minerals, high rock densities (3 g cm^{-3}) and high temperature–high pressure paragenesis. Common features are the presence of hypersthene and clinopyroxene in calcic assemblages, the presence of myrmekite, greyish blue quartz and pleochroic hypersthene in acidic assemblages, with plagioclase and K-feldspar.

We have selected several samples of various ages on the criterion that they correspond to an unambiguous definition of the granulite facies (as quoted above) for which different geological and petrological studies (done previously) yield independent information on their history. The largest part of our samples were obtained through the courtesy of P. Hurley and were mainly studied by Spooner[23], and Spooner and Fairbairn[24]. These are acid and intermediate varieties of pyroxene granulites following the definition of Spooner[23] (instead of 'charnockite' according to Holland's definition[25]). The other samples come from In'Ouzzal (Ahaggar), Ansignan and Agly (Pyrenees), from several different areas in Norway, and also include xenoliths from Le Bournac (France), kinzigites from Beni Bousera (Moroccan Rif) and the Ivrea zone (Italian Alps). In each case, the petrographic description can be found in the literature referenced with a brief description of each area in the caption of Fig. 4.

Chemistry of granulite rocks

For each sample we have determined the Nd isotopic composition and the Sm–Nd concentrations through isotope dilution. For some samples, we have determined the Rb–Sr concentra-

0028-0836/84/060510—06$01.00

© 1984 Macmillan Journals Ltd

tions and Sr isotopic compositions, while in some others, we have used the values published by Spooner and Fairbairn[24]. The analytical techniques used have been described in detail elsewhere[14,26,27], but we wish to emphasize the particular point of zircon dissolution. For every sample, after dissolution in an open Teflon beaker, heavy minerals are dissolved in a closed, pressured Teflon bomb at 205 °C. Indeed, since heavy minerals contain high proportions of rare earth elements (REE)[28], such a technique is crucial for granitoids as well as for granulites. Some workers either do not use bomb dissolution or do not give any indication about their analytical procedure[29–35]. All the corresponding results are dubious and should be used with caution. However, due to a lack of enough reliable analyses in literature, we have used these results in our statistics. However, this incomplete dissolution of zircons may enlarge the real spread of the $^{147}Sm/^{144}Nd$ and the $^{143}Nd/^{144}Nd$ ratios. All the experimental results are reported in Table 1, with error limits.

Our selection represents only 32 specimens of typical granulites and therefore cannot be considered as a fully representative worldwide sample of this facies. However, a comparison between these results and those obtained on granitoids as referred to lower and upper continental crust respectively is of great interest.

In relation to petrological variations within the granulites, Nd and Sm concentrations vary from 3 to 65 p.p.m. and 0.4 to 11 p.p.m. respectively (Table 1). The average values of 28.2 p.p.m. for Nd and 5.3 p.p.m. for Sm are relatively close to those obtained for the upper continental crust and comparable with the average values of the main components of the North American continental crust: for shales, Nd = 31 p.p.m.; for the Precambrian shield composite (north Quebec + Saskatchewan + south-west Quebec) Nd = 30.7 p.p.m. More significant is the relative clustering of the $^{147}Sm/^{144}Nd$ ratios at around 0.121 (Fig. 1*a*). The average value for granitoid rock is around 0.113 and is close to the value for granulites (Fig. 1*b*). In addition, the average value for the whole crust estimated by De Paolo and Wasserburg[36] is 0.116 and estimated by Jacobsen and Wasserburg[37] is 0.119, which are both remarkably close to our average. However, the $^{147}Sm/^{144}Nd$ ratios in the continental crust are not strictly constant since the measured values vary from 0.06 to 0.20 in granulites and from 0.07 to 0.16 in granitoids. When considering basic ortho-derived granulites and xenoliths, the spread largely overlaps the mid-ocean ridge basalt (MORB) field. However, from a statistical point of view, the distinction between acidic continental material and MORB (Fig. 1*c*) is remarkable.

Both the absolute contents and the ratios of Rb and Sr are highly variable (Table 1). Rb and Sr contents vary from 2.4 to 117 p.p.m. (a factor of 49), and from 31 to 870 p.p.m. (a factor of 28) respectively; Sr varies more than the REE. $^{87}Rb/^{86}Sr$ ratio varies from 0.09 to 4.8 (a factor of 55). We emphasize that all values are equal to or larger than the bulk Earth value which is around 0.09. Therefore there is no doubt that the bulk continental crust (lower + upper crust) has a higher Rb/Sr ratio than that of the bulk earth.

Amongst several authors, Heier[4] claimed that rocks of the granulite facies are strongly depleted in Rb relative to Sr. This is true of the Lewisian granulites[38,39] and a few others[24] but does not appear to be a general rule as shown by Leyreloup *et al.*[40], Allègre *et al.*[41] for Bournac granulites and by Spooner and Fairbairn's[24] extensive study. Available Rb/Sr ratios data for granulites are shown in Fig. 2. The observed scatter indicates that some areas are depleted in Rb whereas others are not. The cause of this difference is not understood but must be taken as a fact.

The raw data for the $^{87}Sr/^{86}Sr$ and $^{143}Nd/^{144}Nd$ isotopic ratios (Table 1), uncorrected for age, have been directly reported on the Sr–Nd correlation diagram (Fig. 3). In addition, we have plotted the field defined for granitoids taken from the literature. In their study of Lewisian granulites, O'Nions' group[33,42] have defined a field for granulite with low $^{87}Sr/^{86}Sr$ and negative ε_{Nd}. However, many granulite-facies rocks plot outside this field. In fact, the field for all the granulites would largely overlap that for granitoids.

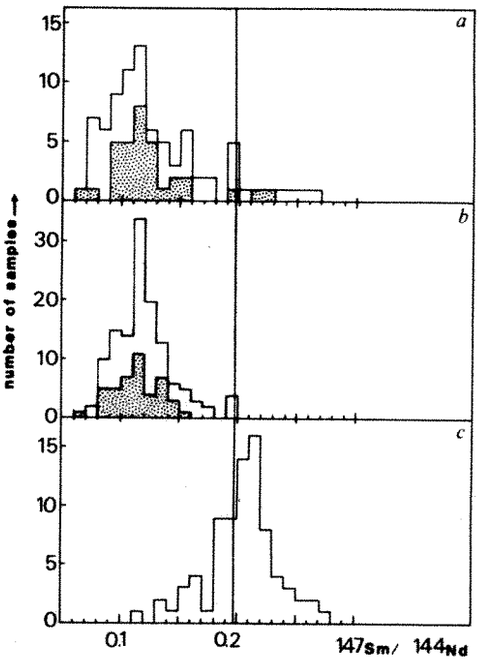

Fig. 1 Histograms of the $^{147}Sm/^{144}Nd$ ratios. *a*, In granulites (data (▩) are from this paper, the others (□) are from refs 29, 30, 32–35). *b*, In granitoids (data (▩) are from refs 14, 20, 52, 74, the others (□) are from 15–19). *c*, In MORB.

Without discussing the detailed age relationships and considering only the geological age we must point out that, as for granitoids, ε_{Nd} values are mainly a function of the rock ages due to fairly constant Sm/Nd ratios of the continental crust. On the other hand, the $^{87}Sr/^{86}Sr$ ratios are more variable but the scatter seems to increase with age. This also reflects the great variability of Rb/Sr ratios.

Model age systematics

The results will now be discussed in terms of model ages of our samples, as defined by McCulloch and Wasserburg[31]. Since continental crust material ultimately derives from the mantle, a model age relative to their mantle source will be estimated. In doing so, the evolution curve of the depleted mantle, as defined by MORB data will be chosen[14,15]. The details of the calculations are given in Table 1 legend.

As the Sm/Nd ratio of the continental crust is fairly constant, the Nd model age is expected to be 'robust' relative to a complex evolution of the continental crust. In contrast the Rb/Sr fractionation history of the crust prevents Sr model age from being geologically significant. A comparison of both model ages will be very useful in deciphering the history of each particular segment of the continental crust.

For each area we have reported the radiometrically determined geological ages of the granulites. In most cases these ages are obtained by whole rock Rb–Sr (often poorly defined) isochrons (Liberia, Tanzania, Columbia, Venezuela, Bournac, Norway, Rogaland and Beni Bousera). In some cases U–Pb ages are available from zircon studies (In'Ouzzal, Amitsoq, Bournac, Ivrea zone, Venezuela). Last, in a few cases, ages have been obtained by whole rock Pb–Pb dating (Venezuela).

Because the Rb–Sr and U–Pb systems are often perturbed by metamorphic events, ages must be interpreted with caution. When a granulite is ortho-derived, the meaning of its age is clear; it probably represents the time of intrusion of its progenitor. When the rock is para-derived, the meaning is more conjectural. Does it correspond to a large-scale rehomogenization contemporaneous with an orogeny[43], or to mixing or the

The Rb–Sr analyses are done either by D. Rousseau (‡), J. Hamet (†) or M. Polvé (*), the others are done by the MIT Group (see references). Blanks for the Rb and Sr analyses done either by D. Rousseau, J. Hamet or M. Polvé are around 70 pg and 160 pg respectively. Blanks for Nd and Sm done either by D. Ben Othman or M. Polvé, are around 100 pg and 70 pg respectively. $^{81}Sr/^{86}Sr$ ratios are normalized using $^{86}Sr/^{88}Sr = 0.1194$; errors are quoted at $2\sigma_m$. Nd is run as Nd+. $^{143}Nd/^{144}Nd$ ratios are normalized to $^{146}Nd/^{144}Nd = 0.7219$, errors are quoted as $2\sigma_m$. The average measured value of Nd standards from Johnson Mattey is 0.511981±0.000015. Nd model ages are given by the intercept between two curves: $(^{143}Nd/^{144}Nd)_{sample} = (^{143}Nd/^{144}Nd)_T + (^{147}Sm/^{144}Nd)_{sample}(e^{\lambda T} - 1)$ and $(^{143}Nd/^{144}Nd)_{DM} = AT^2 + BT + C$. *DM*: Depleted mantle, with $A = 1.53077 \times 10^{-5}$; $B = -0.22073 \times 6.54 \times 10^{-3}$; $C = 0.513078$. *A*, *B*, *C* are chosen to fit the evolution curve of a depleted mantle defined by data on MORB, ophiolites (Bay of Island, Semail), Precambrian mafic volcanics (Kambalda, Kanowna, Onverwacht), komatiites (Cape Smith, Abitibi), Isua supracrustals and meteorites (Angra dos Reis, Juvinas)[64–71]. Sr model ages are given by the intercept between two curves $(^{87}Sr/^{86}Sr)_{sample} = (^{87}Sr/^{86}Sr)^T + (^{87}Sr/^{86}Sr)_{sample}(e^{\lambda T} - 1)$ and $(^{87}Sr/^{86}Sr)^T_{DM} = A'T^2 + B'T + C'$ with $A' = -1.54985776 \times 10^{-4}$; $B' = -1.6007234 \times 10^{-4}$; $C' = 0.70273029$. *A'*, *B'*, *C'* are chosen to fit the evolution curve of a depleted mantle defined as for Nd by data on MORB, ophiolites (Zambales, Toba, Guatemala, Bay of Island), komatiites (Cape Smith, Abitibi), BABI and Allende[64,69,72,73].

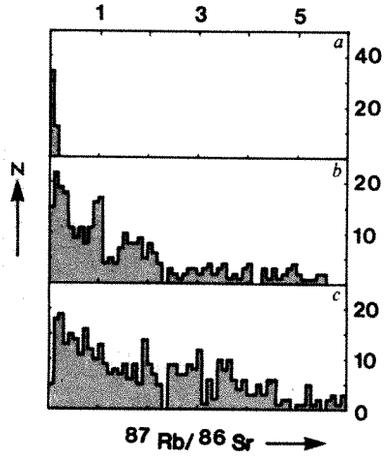

Fig. 2 Histograms of the $^{87}Sr/^{86}Sr$ ratios. *a*, In granulites (data are from this paper and refs 11–13, 23, 24, 34, 38–40, 45, 47, 49, 54, 63, 75–88 and J. Hamet and C.J.A., in preparation). *b*, In granitoids (data are from refs 14, 16, 17, 19, 20, 53, 54, 74, 89–99). *c*, In MORB.

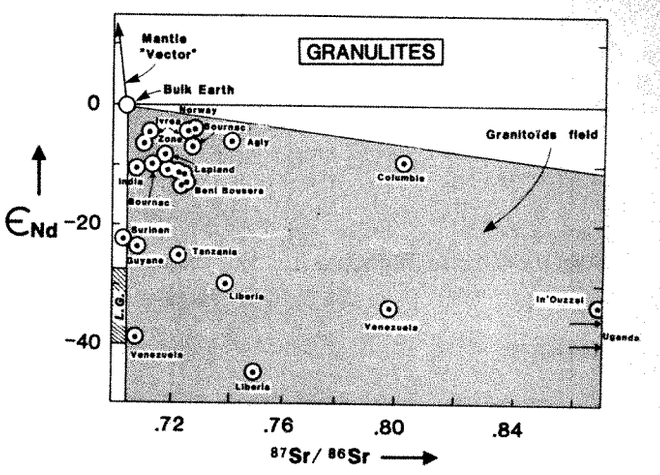

Fig. 3 Data from granulites plotted in the ε_{Nd} versus $^{87}Sr/^{86}Sr$ diagram in comparison with the fields of granitoids and Lewisian gneisses.

age of the sediment sources? In the case where the granitoids present in the same region have the same age, this age is most probably related to a regional episodic event. We will call this age the geological age. Aware of these possible complications, we have plotted the geological age versus the Nd model ages in Fig. 4*a* for the granulites. Additional data are for Lewisian gneisses[33], Lofoten, Norway[30], Australian samples[34] and Antarctic[29].

As can be seen, the Nd model ages are in most cases greater than the geological ages. This is especially true for the younger samples: Bournac, Norway, Ivrea zone, Beni Bousera, and for the older African gneisses (Liberian, Uganda, Tanzania, In'Ouzzal).

For some older samples such as those from India, Australia, Columbia, Guyana and Scotland, the Nd model age is close to the 'geological age'. For two samples from Venezuela, the 'geological age' is greater but is also poorly determined.

In several cases, it is possible to determine with reasonable accuracy the time at which the rocks were metamorphosed to granulite facies. The geological significance of this event is more clear than the previously discussed geological ages. This is the case for samples from In'Ouzzal (Ahaggar), Imataca (Venezuela), Lofoten and Bamble (Norway), Bournac (France), Ansignan (France), Beni Bousera (Morocco), the Ivrea zone (Italy), and the Lewisian gneisses (Scotland).

The garnet-whole rock Sm–Nd age for In'Ouzzal (D.B.O. and C.J.A., in preparation), the zircons of some metasedimentary rocks[44] and petrological studies all give an age of 2,100 Myr which also corresponds to the age of the Tassendjanet pluton and of a main orogenic episode in this area.

In the Imataca area (Venezuela) studied by Hurley *et al.*[45,46] and Gaudette *et al.*[47] granulite-facies metamorphism occurred at 2,000 Myr which also corresponds to an important tectono-metamorphic event of this area.

The Lewisian complex studied by Hamilton *et al.*[33] yields an age of about 2,600 Myr for granulite-facies metamorphism which is the age of a major orogenic event associated with granitoid injection.

The Lofoten occurrence in Norway studied by Jacobsen and Wasserburg[30] gives an age of 1,700 Myr for granulite facies metamorphism. This age corresponds in Norway to a major tectono-metamorphic event with associated plutonism.

In the Bamble area, also in Norway, the granulite facies metamorphism is dated at 1,000 Myr, an age which also corresponds to the major tectono-metamorphic event in this area, again associated with important plutonism[49–51].

In the Bournac case, a Sm–Nd garnet whole-rock isochron[52] gives an age of 380 Myr apparently linked to the end of the Caledonian orogeny and slightly older than the intrusion of the Velay granite, the latter being 300 Myr old[53].

The Agly granulite was formed 300 Myr ago during the Hercynian orogeny and is associated with granitoid intrusions such as Querigut and Milhas[54].

The Ivrea zone granulites are 260 Myr old (M. Polvé and C.J.A., in preparation), the same age as the granitic intrusions in the neighbouring amphibolite facies zone[55,56].

The Beni Bousera granulite-facies metamorphism is quite young (20 Myr) (M. Polvé and C.J.A., in preparation). Such a metamorphic event seems to be linked with the regional tectonics[57,58]. However, no important plutonism is presently known in the area.

Comparison of these ages for granulite metamorphism with the Nd model age clearly shows that they are generally much younger. This information is almost the same as the one given by the geological age. The Venezuela case seems to be an exception. However, the geological age is very uncertain. In our opinion the most probable age is 2,800 Myr. The smallest time interval (200 Myr) is for the Lewisian gneisses. In other cases the time interval between Nd model age and granulite facies metamorphism is from 500 to 1,200 Myr.

On the other hand, age determinations seem to indicate that granulite-facies metamorphism seems always to be linked to major orogeny. It does not reflect a continuous reequilibration process at depth stopped by the upwelling of a piece of lower crust to the surface during some event not related to any large orogenesis. If such reequilibration at depth followed by 'upwelling' occurs, this event is related to a major orogenesis.

Geological consequences

Following McCulloch and Wasserburg[31] and O'Nions *et al.*[59], we interpret the Nd model age as the age of segregation from the mantle (EXCOD). The other ages, either the global geological ages or the better defined metamorphic ages, that we use for comparison with the Nd model ages, are clearly linked to orogenic processes and are sponsored to date INCOD. If this dual identification is correct we can draw the following conclusions: EXCOD has preceded INCOD by a large time interval for young granulites and for many of the older ones too. In these cases it seems that EXCOD and INCOD are two separate phenomena with INCOD operating on preexisting continental crust. This is only true if rocks have not been multiply metamorphosed in granulite facies.

For some Precambrian samples, ages of EXCOD and INCOD are similar. EXCOD and INCOD are still possibly two separate processes but would follow each other with a rather small time interval. The model proposed by Moorbath[43] for a single episode

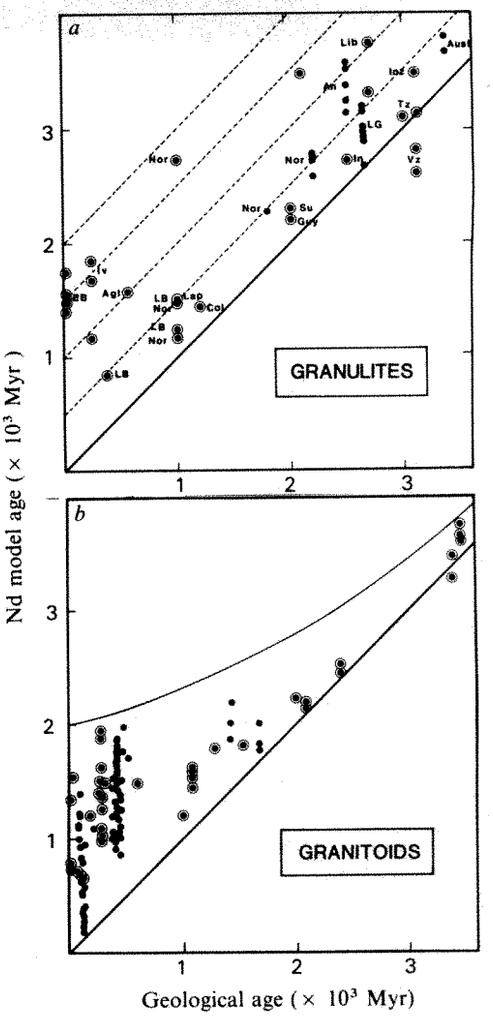

Fig. 4 Nd model age versus geological age diagram. *a*, For the granulites, our data (◉) are plotted together with other data (●) from refs 29, 30, 32–35. Underlined name samples correspond to well-known INCOD. *b*, For the granitoids, our data (◉) are from 14, 20, 52, 74, the others (●) from refs 15–19. Inz: In'Ouzzal formation (Ahaggar)[100–105] the primary age of these rocks is 3,300 to 3,100 Myr (ref. 41 and C.J.A. and D. Rousseau, in preparation) and the granulite metamorphism is 2,100 Myr[105] old. This age corresponds roughly to the age of a major orogeny in this area and to the age of granitic intrusions (Tassendjanet pluton). Lib: Liberian granulites, from Nimba Range and Grand Cape Mountains. The major tectonometamorphic event in this province is 2,800 Myr to 2,700 Myr old[46,89] but 2,000 Myr ages corresponding to the Eburnean orogeny can be found. Granitoids in this area are also 2,600 to 2,700 Myr old[46,89]. Vz: Imataca complex (Venezuela)[45–47] the geological age of the basement is 2,800 to 2,700 Myr old[47] the major metamorphic event is 2,000 Myr old. Granitoids intrusions occurred at 2,700 Myr[45,46] and 2.1 Myr. Guy: Guyana complex (Kanuku and Bakhuis Mountains)[47,48,75,106]. Basement is 2,060 Myr for the Bakhuis Mountains[106] and 2,180 Myr old for the Kanuku formation[75]. The major tectonometamorphic event and the related large granitic complexes is the 2,100–2,000 Myr transamazonian event[75]. Ug: Western Nile complex (Uganda)[107–109]. The granulites had been dated, not very accurately, at 2,600 Myr[88] and granitoid intrusion is 550 Myr old[109]. Tz: Tanzania granulites from Msagali area. A poorly defined isochron gives an age of 2,690 Myr[88] but older ages may be possible. Granitoids from the north (Tanganikan shield) and south (Ubedian granites) are 1,800–2,000 Myr old[108]. The whole system seems to have been affected by the Mozambican orogeny: 1.1–0.65 Myr ago[108]. In: Granulites from Mysore and Madras State (India)[98]. The granulites and probably the granitoids are 2,700 Myr old[23,24,110]. The age of the granulite facies metamorphism is still debated: 2,000 Myr[111] or about 2,500 Myr[112]. Col: Santa Martha Sierra (northern Columbia). The granulites are 1,270–1,370 Myr old[76,113], granitoids in this area are about 1.0 Myr old. Nor: Granulites from south Norway (Bamble, Rogaland). Rogaland: granulites are dated at 1,000–1,200 Myr[114] and granulite metamorphism is supposed to be 1,000 Myr old[115] but a possible metamorphic event may have occurred at about 1,400–1,500 Myr[78,79,115]. Later intrusions took place at about 900–950 Myr[116,117]. Bamble: [50,51,118] This region has suffered two major metamorphic events: 1,600 Myr (Svecofennian) and 1,000 Myr (Sveconorvegian) the latter being HP event[49]. Granites are about 1,000 Myr[50,51]. Lap: Valjok area (Lapland). Granulite metamorphism is supposed to be 1,000 Myr old (J. Touret, personal communication). LB: Bournac pipe, Massif Central, France(refs 40, 41, 63, 119 and J. Hamet and C.J.A., in preparation). An age of at least 1,000 Myr has been found for the first (granulitic) metamorphic event, followed by an hercynian event. Agl: Ansignan and Agly para- and ortho-derived granulites (Pyrenees, France)[54]. A first metamorphic event occurred at 550 Myr. Later the granulite metamorphism is probably hercynian, related to the emplacement of the Pyrenean granitoids (350 Myr). BB: Beni Bousera granulites (Rif, Morocco) (refs 120, 121 and M. Polvé and C.J.A., in preparation). U–Pb, Sm–Nd, Rb–Sr dating show that the recycled material is very old and the granulite facies is young (20 Myr). Iv: Valle Strona–Ivrea zone (Italian Alps). This complete section of upper mantle, lower and intermediate crust is well known 122–127. The recycled material of the para-derived samples is 1,600 Myr–2,500 Myr old (ref. 128 and M. Polvé and C.J.A., in preparation). Two metamorphic events are known around 475 Myr[90] and 260 Myr (M. Polvé and C.J.A., in preparation). Granitic intrusions in the neighbouring zones are 270–275 Myr old[90].

of crustal differentiation may work in special cases but does not seem to be generally the case. A similar diagram can be constructed for granitoids for which the geological ages are well defined and correspond to the age of the intrusion[14–17 19,20] and compared with that for granulites (Fig. 4*b*). This comparison emphasizes two points: for young samples the two diagrams are very similar and thus recycling processes appear to be important in both cases. For old samples they are largely more scattered in the granulite cases than in the granitoid one.

A direct comparison between lower and upper crust is difficult at this stage, since upper crust contains large amounts of granitoid rocks but also a large proportion of gneisses and metamorphic terranes, for which the relative volumes are unknown. Granitoids seem to have a history that is easier to decipher and to systematize than that of granulite rocks, but we must remember that granitoids are produced by the melting of large volumes of rocks (including crustal rocks). Therefore such processes may homogenize relatively large volume of rocks giving a kind of statistical regional average.

Nd model ages are not sensitive to crustal events. Comparing Sr and Nd model ages, a Rb systematic depletion in lower crust should correspond to Sr model ages superior to Nd model ages. Our data (Table 1) show that this case exists but the reverse (Sr model ages < Nd model ages) also exists, sometimes within the same area. This demonstrates the non-systematic depletion of Rb.

Conclusions

Granulite-facies rocks have Sm/Nd ratios identical to those of granitoids from the upper crust. These values are roughly constant for continental crust material (about 0.121 for $^{147}Sm/^{144}Nd$). Thus internal differentiation of the continental crust apparently involves no fractionation of Sm and Nd. The Rb/Sr ratios are more variable and there is no unique signature characterized by systematic depletion in Rb. In some areas, rocks appear depleted in Rb while in others they are not. Such variability in the lower crust should be considered seriously. If on the average, the lower crust is more depleted in K, Rb, U and Th than the upper crust, as shown by heat flow studies[60] and/or budget calculations[61,62], the reason may be that the lower crust contains a larger proportion of basic rocks than the upper crust. If this hypothesis proves to be true, we shall have to change our estimates of the lower crust composition by taking

an average of acid and basic components. For the Sm/Nd ratios this is unlikely to change dramatically the estimates based on the present study, since basic intrusions, either tholeiites, alkaline or calcalkaline basalts, have a light REE enriched pattern resembling that of granitoids[63]. On the opposite, the average Rb/Sr ratio of the lower crust will probably be considerably lowered. Future work on granulites should aim to estimate the respective proportions of basic and acid rocks in the lower crust.

The model-ages relationship clearly shows that recycling processes are important factors for building the lower continental crust. In most cases the lower crust is made up of preexisting igneous or sedimentary material. As shown by Touret[51], granulitic rocks also contain a large proportion of metasediments. If these characteristics are true, and assuming that granulites are really the lower part of the continental crust, it is possible to propose a model for continental development: most of the new continental segment is developed on a basin, located at the edge of the continent but with a continental basement. This basin is stressed, folded, intruded by mantle-derived melts, subjected to anatexis at several levels, and then transformed in a new continental segment. This segment has then the property that its upper part is made of new continental material intruded by anatectic granites which are partly reworked lower crust, partly locally derived, with its lower part made of older continental material. A small basin is a possible location for such an episode of continental growth. This model fits the constraints given by the petrogenesis of granitoids and granulites as determined by geology, petrology and isotope studies.

We thank D. Demaiffe, S. Fourcade, A. Michard, J. Touret and particularly Professor P. M. Hurley who provided us with the samples analysed in this study, together with relevant information. J. F. Minster and C. Jaupart critically read the manuscript. This is IPGP contribution 673.

Effect of chromosomal position on amplification of transfected genes in animal cells

Geoffrey M. Wahl, Bruno Robert de Saint Vincent* & Margaret L. DeRose

The Salk Institute, PO Box 85800, San Diego, California 92138, USA

A single protein (CAD) contains the first three enzymatic activities of de novo *uridine biosynthesis. The chromosomal location of CAD genes introduced into Chinese hamster ovary cells significantly affects the frequency and cytogenetic result of their amplification. The amplification frequency in one transformant is 100-fold that of the others; in another, amplification of donated genes inserted near a centromere results in chromosome instability and rearrangements.*

GENE amplification in mammalian tissue culture cells occurs spontaneously, with high frequencies, and is a common mechanism of resistance of animal cells to diverse agents[1]. Phenotypic reversion of mutations engendering temperature-sensitive[2] or kinetically altered[3] proteins also occurs by gene amplification. Cytogenetically gene amplification results in expanded chromosomal regions which band abnormally by the trypsin–Giemsa method (often called homogeneously staining regions, or HSRs) or acentric extrachromosomal elements (called double minute chromosomes, or DMs) (see ref. 4 for a review). Since the amplified regions are 100–2,000 kilobases (kb)[4–10], far longer than the structural genes under selection, it is likely that chromosomal sequences or structures distant to the selected gene are involved in amplification. Since large amounts of DNA are co-amplified with the selected gene, 'sequence' amplification is often a more accurate term.

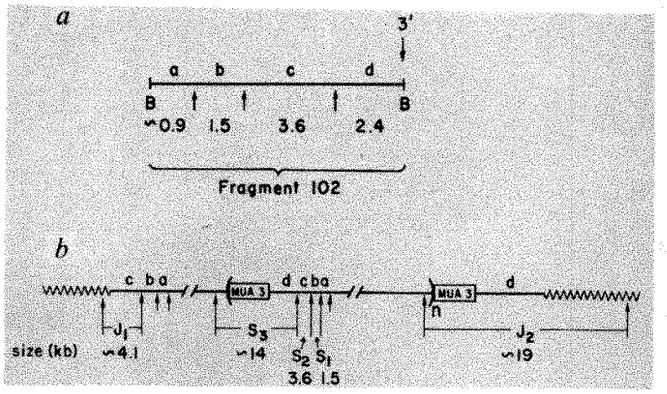
The abnormal chromosomal structures typical of gene amplification in drug-resistant tissue culture cells also occur in untreated spontaneous tumour cells[11–15]. Cellular analogues of retroviral oncogenes are sometimes amplified in HSRs and DMs[11,14,15]. Amplified proto-oncogenes are overexpressed in several tumour lines[12,14,15] supporting the hypothesis that elevated expression of cellular oncogenes could be involved in tumorigenesis (see refs 16–18 for reviews).

The numerous examples of gene amplification emphasize that it can occur in many chromosomal regions. As in bacteria[19], the chromosomal position of a mammalian gene can determine the amplification frequency and mechanism, and the size and stability of the resulting amplified regions. The various examples of eukaryotic sequence amplification differ significantly, reflecting the differences between cell lines and the selective agents used as well as the chromosomal positions of the genes. In order to assess directly the contribution of chromosomal position in sequence amplification, we studied the amplification of a cloned CAD gene inserted by gene transfer into different locations in the chromosomes of CAD-deficient Chinese hamster ovary cells (CHO) cells. [CAD is a multifunctional protein which contains the first three enzymatic activities of *de novo* uridine biosynthesis: carbamyl phosphate synthetase, aspartate transcarbamylase and dihydroorotase.]

High-frequency amplification

Purified DNA sequences introduced into mammalian cells integrate into chromosomes in an apparently random fashion[20–22]. If chromosomal position affects gene amplification, it should be possible to use gene transfer to screen for chromosomal sites which engender unusual forms of amplification. Two parameters which could be altered by changing gene position are the frequency and the cytogenetic consequences, for example, rearrangements associated with amplification, of its amplification.

To establish whether either of these parameters is affected by changing gene position, we introduced cloned genomic copies of the Syrian hamster CAD genes[20] into the chromosomes of CAD-deficient (Urd-A)[23] mutants of CHO cells using the calcium phosphate precipitation technique in the absence of carrier DNA[24,25]. Transformants expressing the donated Syrian hamster CAD genes can be identified by their ability to grow in the absence of uridine[20]. Four transformants were isolated which contain approximately three to six functional donated CAD genes. The CAD activity in each transformant was approximately the same as that of the wild-type CHO K1 cells (see Table 1). This agrees with our previous finding that the Syrian hamster CAD gene is expressed at approximately one-quarter the level of the Chinese hamster CAD gene[20]. Each transformant maintained the donated genes without restriction pattern changes after passage for 90 generations without selection (data not shown).



Due to their similar levels of CAD expression, transformants and wild-type CHO K1 cells are sensitive to the same concentrations of PALA (*N*-phosphonacetyl-L-aspartate, see LD_{50} in Table 1), a specific inhibitor of the aspartate transcarbamylase activity of CAD[26]. Since PALA resistance has been found only when the CAD gene is amplified[27,28], we used the frequency of PALA resistance as an indicator of CAD gene amplification frequency. Table 1 shows the number of PALA-resistant ($PALA^r$) colonies that arose in transformants T1, T5, T6 and T7 at the three PALA concentrations tested. Transformant T5 differs from wild-type Syrian hamster[28], from CHO K1 cells and from the other transformants: in T5 the frequency of PALA resistance is at least 100 times greater and T5 resists higher concentrations of PALA in a single step even though the other transformants have equivalent or higher aspartate transcarbamylase specific activities. All of the $PALA^r$ T5, T6 and T7 clones tested maintain their initial levels of PALA resistance when grown for 60 generations in the absence of the drug, indicating that PALA resistance is relatively stable in these lines. The amplified CAD genes in one $PALA^r$ T1 mutant appeared to be much less stable (see below).

To determine whether high frequency PALA resistance in transformant T5 results from amplification of donated CAD sequences, DNA isolated from the parental transformant and from five independently isolated $PALA^r$ mutants of T5 was digested with endonuclease *Sst*I and then analysed by blot hybridization[29,30] using the CAD-specific probe P102[31] (Fig. 1). The bands representing the endogenous CHO CAD genes (labelled CHO_1 and CHO_2) are easily resolved from the three Syrian hamster CAD gene bands (labelled S_1, S_2, S_3). It is clear that the donated sequences are amplified in each of the $PALA^r$

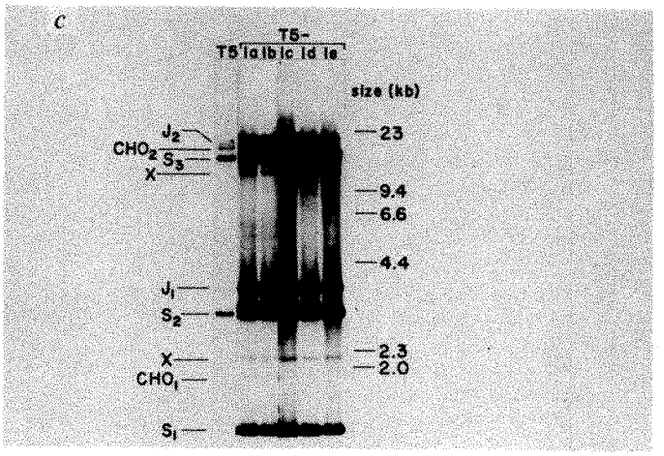

Fig. 1 Analysis of the donated CAD genes in transformant T5 and in PALA^r mutants. ***a***, Map of CAD gene fragment 102. 102 is an 8.6-kb *Bam*HI (B) fragment derived from the 3'-end of the 25–30-kb Syrian hamster CAD gene and contains only unique sequences[31]. The map of fragment 102 published previously had an inversion of fragments b and c[20]. ↑ indicates *Sst*I cleavage sites. ***b***, Simplified map of the inserted sequences in transformant T5. The donated array consists of four to six CAD genes in a head-to-tail tandem array (one indication of this arrangement is the presence of fragment S_3 which has been shown by hybridization analysis to contain sequences at the 5' end of one CAD gene, vector sequences, and the 3' end of another CAD gene). Only the relevant *Sst*I sites (↑) are shown. Not to scale. ***c***, Hybridization of *Sst*I-digested DNA isolated from T5 and PALA^r T5 mutants with fragment 102. The lanes indicate the clones used as the source of the genomic DNA. T5 is the parental transformant, and T5-1a to T5-1e are independent PALA^r mutants isolated from T5 after selection in 250 μM PALA. Each mutant was expanded from a single, well-isolated colony for DNA isolation. Mutant T5-1d is the same as T5-S1-3 shown in Figs 2 and 3. Exposures, which show the endogenous CHO CAD gene fragment CHO_2 more clearly, demonstrate that all lanes contain approximately the same quantity of DNA. CHO_1 and CHO_2 indicate the Chinese hamster CAD gene fragments, S_1, S_2, S_3 are the donated Syrian hamster CAD gene fragments, J_1 and J_2 are the joints between the donated and CHO DNA, and X is a fragment produced by inefficient *Sst*I cleavage which is also seen after cleavage of CAD cosmid DNA. **Methods:** Cellular DNAs (10 μg) were digested with a 5–10-fold excess of *Sst*I, fractionated by electrophoresis through a 0.7% agarose gel, and analysed by the Southern blot hybridization technique[29,30]. The DNA was depurinated *in situ* in 0.25 M HCl for 10 min (instead of 20–30 min as described previously[30]). The filter was hybridized with 3×10^6 c.p.m. per ml of nick-translated[47] p102 (see Fig. 1*a*) in the presence of 10% dextran sulphate for 16 h and washed as described previously[30].

T5 mutants. Three other conclusions derive from this experiment. First, even though each T5 mutant was isolated after a single step of selection, there is an approximately 25–50-fold increase in copy number (determined by densitometry of autoradiographs exposed in the linear range of the film). This compares with a 5–10-fold increase in PALA^r mutants of other transformants (for example, see results below for transformant T1). Second, the molecular structure of the amplified donated sequences is identical in all independently isolated T5 mutant. Third, amplification of the donated CAD genes in T5 does not result in their rearrangement. The bands labelled 'X' were observed after restriction digestion of purified cosmid DNA, and probably represent low efficiency cleavage sites for endonuclease *Sst*I. Fragments 'J_1' and 'J_2' are derived from the junctions between the donated and flanking CHO DNA as described below.

Amplification mediated by flanking sequences

DNA blotting experiments shown above for transformant T5 and below for transformant T1 (data not shown for the other transformants) demonstrate that donated CAD genes can be amplified in each transformant. All of the transformants were derived from the same recipient cell line (Urd-A), and all were transformed with the same CAD cosmid. Thus, the capacity for high frequency amplification in T5 is not related to the DNA used or to some general characteristic of the Urd-A cells following transfection. Since the frequency of dihydrofolate reductase (DHFR) gene amplification is essentially the same in CHO K1, Urd-A and T5 (data not shown), T5 is not a genetic variant capable of amplifying all sequences at a high frequency. Therefore, the high frequency amplification in T5 relates either to the organization of the donated sequences or to an effect of the position in which they are inserted.

The restriction analysis shown in Fig. 1*c* indicates that T5 contains four to six donated genes (for example, compare the intensities of S_1–S_3 with those of CHO_1 and CHO_2). The *in situ* hybridization analysis in Fig. 2 shows that the donated genes in T5 are contained in a single chromosomal location and that amplification occurs near to or at this site without obvious chromosome rearrangements. Hybridization analysis with different probes has shown that fragment S_3 (Figs 1*c*, 3) contains sequences at the 5' end of one CAD gene, the adjacent vector, and the 3' end of the next CAD gene, indicating that the donated genes are in a head-to-tail array (see Fig. 1*b*). From previous studies, we infer that the tandem array arose by homologous recombination either before or after chromosomal integration[22,32]. Since tandem arrays mediate amplification by unequal sister chromatid exchanges in prokaryotes[19] and yeast[33], we tested whether such exchanges occurring within the tandem array in T5 cause the observed high frequency amplification.

Reciprocal unequal exchanges within the tandem array of CAD genes should generate two chromatids with unequal numbers of CAD genes. After mitosis and cell division, only the daughter cell receiving the chromosome with the greater number of CAD genes will survive the PALA selection. Thus, the abundance of joint sequences between donated and CHO DNA should not increase following amplification by unequal exchange since half of the joint sequences are lost in the cell which does not survive the selection. To test this prediction, we identified the joints between the donated and CHO DNA and measured their abundance after amplification in five independently isolated mutants.

Since there is a single insertion site in T5, the joints between the CHO and donated DNA should be contained in two restriction fragments which do not correspond to the known CAD gene restriction map. These fragments should have unique sequence abundance. Fragments J_1 and J_2 (Fig. 1*c*), which hybridize with fragment 102, are the only two *Sst*I restriction fragments which fulfill these criteria. Furthermore, since probes for other regions of the CAD gene do not reveal other novel fragments, the sequence disruption caused by gene insertion is

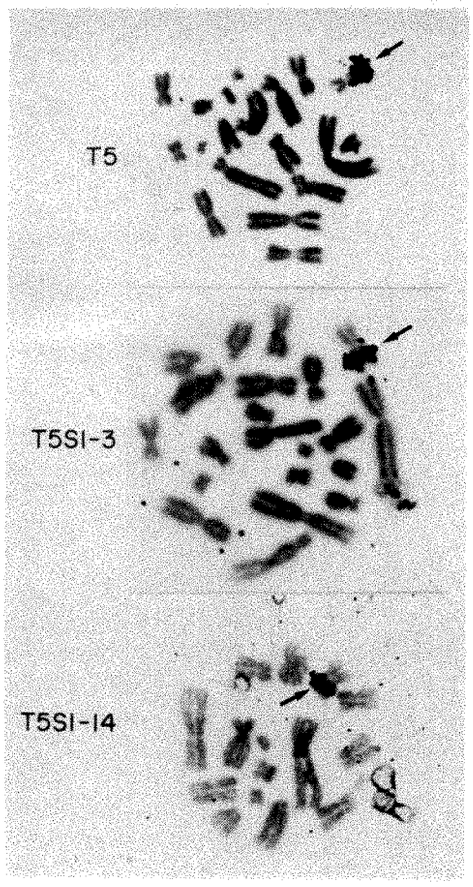

Fig. 2 Localization of the donated CAD genes in T5 and PALA^r T5 mutants by *in situ* hybridization. Cell lines used for the metaphase spreads are indicated in each panel. Hybridization to the chromosomes indicated by the arrows represents the only significant hybridization observed in 10 metaphase spreads from each cell line. The dense packing of grains in these exposures, the unequal hybridization to chromosomes prepared from the different cell lines at different times, and the uneven hybridization seen across the slides prevents these data being used to determine the relative number of CAD sequences in each cell line.
Methods: Methods for spread preparation and *in situ* hybridization have been described in detail previously and were modified only by use of ^{3}H-labelled rather than ^{125}I-labelled p102[5]. The probe was nick-translated p102. Exposures were for 2 weeks at −70 °C.

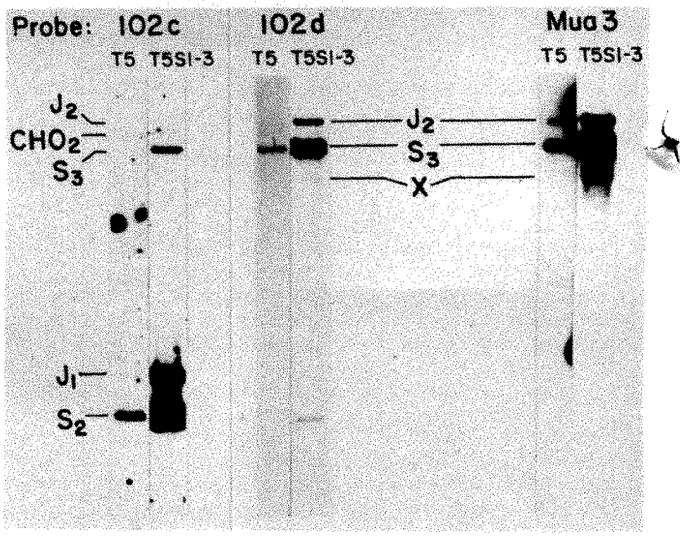

Fig. 3 Analysis of joint fragment amplification in transformant T5 and PALA^r mutant T5-S1-3. The blot used in Fig. 1 was washed to elute bound counts (see below) and then hybridized with the indicated probes. For simplicity, we show the pattern of hybridization to DNA isolated from only one PALA^r T5 mutant since all the hybridization patterns from the five mutants analysed were identical (for example, Fig. 1*c*).
Methods: The blot shown in Fig. 1 was washed with boiling 0.1 × SSPE, 0.1% SDS briefly to remove the bound counts. Subsequent hybridization reactions contained 3–5 × 10^6 c.p.m. per ml indicated probes, and all reactions were performed as described in the legend to Fig. 1. Film exposures: 84 h for 102c, 72 h for 102d; 120 h for probe MUA3. Reduced hybridization signals were seen with probe 102d because it was 2 weeks old at the time it was used.

localized to fragment 102 (see Fig. 1*b*). When subfragments 102C and 102D (Fig. 1*a*) were hybridized to the blot shown in Fig. 1*c*, subfragment 102C hybridized preferentially with J_1 and S_2, and subfragment 102D and vector sequences hybridized with both J_2 and S_3 (Fig. 3). These data agree with the map in Fig. 1*b*. The results show that J_1 and J_2 are the joints between the donated and CHO DNA, and demonstrate that the joint fragments are amplified in the PALA^r T5 mutants to the same extent as the CAD sequences which they flank (see Figs 1*c*, 3). Thus, it is unlikely that amplification of the donated genes in T5 occurs by reciprocal unequal exchanges within the donated sequences. The data indicate that the amplified unit extends beyond the CHO-donated DNA junctions, implying that high frequency amplification in T5 is related to the position of the inserted sequences in the genome.

Chromosome rearrangements

The genetic, molecular and cytogenetic aspects of amplification of the donated genes in transformant T1 contrast with those observed in transformant T5. The frequency of amplification (10^{-5}–10^{-6}), maximal level of amplification (5–10-fold) and resistance to PALA attained in a single step are similar in T1 and wild-type CHO K1 cells (see Table 1). In contrast to transformant T5 (Fig. 2), CAD gene insertion in T1 is accompanied by numerous CAD gene restriction fragment rearrangements (Fig. 4). Since T1 contains an *Sst*I restriction fragment which co-migrates with and has the same hybridization characteristics as fragment S_3 of transformant T5, T1 must also have a core of CAD genes present in a head-to-tail tandem array. The numerous other *Sst*I fragments which hybridize with fragment 102 indicate this tandem array is surrounded by rearranged CAD sequences (two fragments are approximately the same size as CHO_1 and CHO_2 and obscure them). All of these sequences amplify to the same degree without further rearrangements (see Fig. 4, lane T1-1), indicating the amplified unit extends beyond the boundaries of the inserted DNA.

Figure 5 shows the location of the inserted sequences in T1 and the cytogenetic consequences of their amplification. A single insertion site coinciding with the centromeric constriction of a large telocentric chromosome was seen in the 12 metaphase spreads examined. Amplified sequences in independently isolated PALA^r mutants of T1 were found in different chromosomal locations. In mutant T1-1, an entire arm of one medium-sized metacentric chromosome contains most if not all of the amplified sequences. A second chromosome which is very similar to the parental chromosome with regard to the number and location of donated sequences was also found in 14 out of 15 spreads of T1-1. By contrast, the amplified CAD sequences in T1-2 often reside in one or more small chromosomes or chromosome fragments (see Fig. 5, panels T1-2). Preliminary studies of T1-2 show that after passage in the absence of PALA for 40 generations gene copy number decreases by at least half and PALA resistance is diminished. In five out of eight spreads

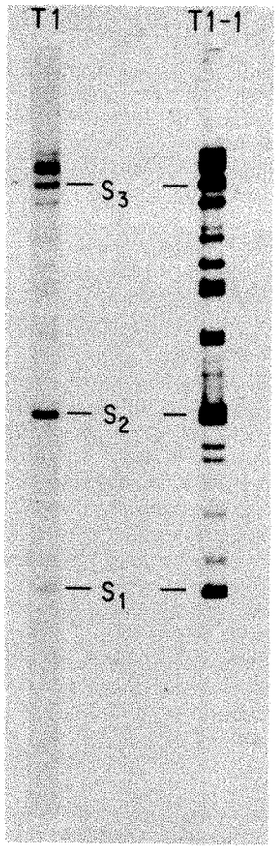

Fig. 4 *Sst*I fragments in T1 and PALA^r mutant T1-1 which hybridize with CAD fragment 102. The lanes indicate the clones used as the source of the DNA. T1 is the parental line and T1-1 is a mutant selected to resist 250 μM PALA. The positions of the normal Syrian hamster fragments are indicated by S_1, S_2 and S_3 (see Fig. 1*b*). The other fragments come from rearranged Syrian hamster CAD fragments. The restriction digestion, blotting and hybridization conditions are described in the legend to Fig. 1. The ethidium bromide staining pattern showed about twice as much T1-1 as T1 DNA. The numerous rearranged Syrian hamster bands obscure hybridization to the CHO CAD gene fragments. Overexposed autoradiograms showed that all CAD sequences amplified in T1-1 are found in T1, and all amplify to the same extent.

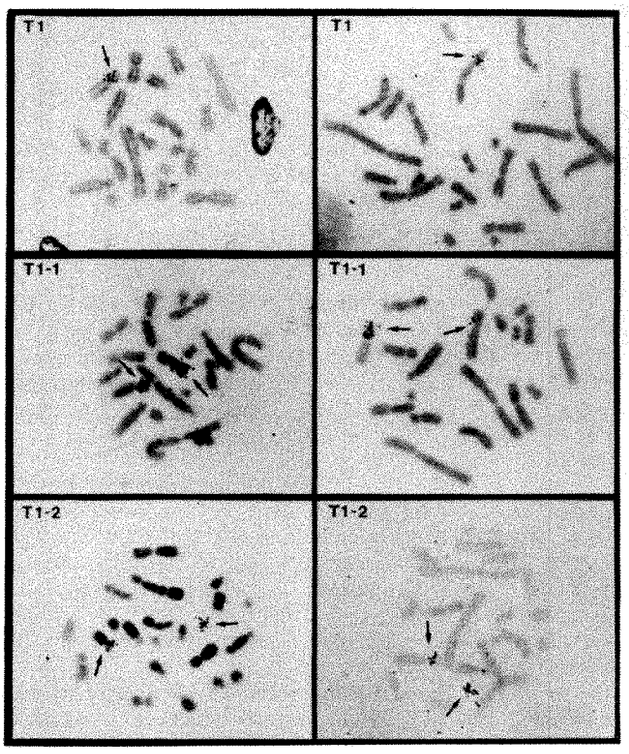

Fig. 5 *In situ* hybridization analysis of T1, T1-1 and T1-2. Representative metaphase chromosome spreads from the indicated cell lines were hybridized with ^{3}H-labelled p102 as described in the legend to Fig. 2.

of T1-2 the donated genes occurred in a chromosome which resembles that found in the parental transformant (T1) and two out of eight metaphase spreads revealed amplified sequences at chromosome telomeres.

Discussion

We used *in vitro* gene transfer to introduce cloned CAD genes into new chromosomal locations in CAD-deficient CHO cells to determine whether position affects the frequency or cytogenetic result of CAD gene amplification. We found that both can be affected significantly by gene position. For example, the donated genes in transformant T5 amplify approximately 100 times as frequently as those in three other transformants or the endogenous CAD genes in several wild-type cell lines. Furthermore, the donated genes in T5 are amplified 25–50-fold after the first selective step in contrast to the 5–10-fold increases seen in the other transformants or several wild-type lines[27,28].

The transfected CAD genes in T5 are in a head-to-tail tandem array 200–300 kb long. Within the array, each CAD gene contains *Alu*-like elements repeated in many introns[34] and the vector sequences are repeated every 40 kb. Such a structure should provide many opportunities for amplification mediated by homologous unequal exchanges. However, we have found no evidence that high frequency amplification in T5 results from reciprocal unequal exchanges within the tandem array. The data agree better with an amplified region which includes the donated sequences and extends into the flanking chromosomal DNA. The amplified region in the three other transformants examined

Table 1 Characterization of transformants T1, T5, T6 and T7

Cell line or transformant	CAD specific activity (μmol per mg protein per 30 min)	LD_{50} (μM)	Frequency of resistance (colonies/3×10^5 cells)		
			100 μM PALA	After selection in 250 μM PALA	1 mM PALA
CHO-k1	0.27	20–30	ND	3	0
T1	0.17	5–10	0	1	0
T5	0.19	5–10	130	152	75
T6	0.33	20–30	1	ND	0
T7	ND	20–30	1	ND	0

CAD-specific activity was determined by measuring the ATCase activity as described previously[20]. The LD_{50} refers to the PALA concentration (μM) required to reduce the plating efficiency of 10^3 cells per 35-mm dish by 50%. The frequency of PALA resistance was determined by seeding 3×10^5 cells per 10-cm dish, allowing attachment to occur overnight, and then challenging the cells in the indicated concentrations of PALA. The number of colonies which developed after 3–4 weeks of selection were then determined by counting the plates after fixing with methanol and staining with Giemsa. ND, not determined.

also extends into CHO DNA. The donated unit in these lines consists of a core of tandem CAD genes flanked by rearranged CAD sequences (Fig. 4). Thus, neither intact nor rearranged CAD sequences can mediate their own amplification by reciprocal unequal exchanges which occur solely within the donated array: flanking CHO DNA participates in the amplification of the transfected genes in each transformant. Hence, if unequal exchanges can cause sequence amplification in mammalian cells, it is likely that factors other than extended regions of sequence homology are required to initiate or mediate the process.

One model for amplification in T5 which agrees with the large single step increase in gene copy number is that unscheduled rounds of synthesis of the donated sequences are followed by recombinational events to generate a stable amplified region[35–37]. Unscheduled DNA synthesis mediates chorion gene amplification in *Drosophila*[38] and has been postulated to lead to DHFR gene amplification in mammalian cells[39], the *in situ* replication of simian virus 40 and polyoma sequences in transformed cells[36,40] and the amplification of adenine phosphoribosyl transferase-thymidine kinase genes transfected into mouse cells[37]. It is tempting to speculate that high frequency and high level amplification in T5 occur because gene insertion disrupts a domain or sequence that controls the replication of an adjacent region, thereby allowing frequent unscheduled synthesis of the donated array.

Gene amplification frequently occurs at sites of chromosome rearrangements[5,41,42]. While obvious cytogenetic changes did not occur in PALA^r T5 mutants, significant chromosomal rearrangements did occur during amplification of the donated genes in T1. Interestingly, the CAD genes were inserted near to a centromere in T1 but in the middle of a chromosome arm in T5. PALA^r T1 mutants retain the chromosome with the donated genes and contain the amplified copies of these genes in another chromosome (in T1-1) or in extrachromosomal elements or small chromosomes (in T1-2). Similar observations to those made in T1 have been reported for the amplification of sequences in IMR-32 neuroblastoma cells[43]. The apparent retention of the parental chromosome and the appearance of amplified sequences in other chromosomes in PALA^r T1 mutants suggests that sequence amplification near or at a centromere is lethal in cells with only one copy of this chromosome. Perhaps an event such as nondisjunction is first required to generate a cell with two copies of the chromosome containing the inserted CAD genes. Amplification in one of these chromosomes could then generate a dicentric chromosome which undergoes a breakage–fusion–bridge cycle[44] to yield chromosome fragments which attach to telomeres of other chromosomes as in T1-1, or remain free and engender an unstable phenotype as in T1-2. A similar model has been proposed recently to explain the frequent telomeric location of amplified DHFR minigenes in CHO cells[42]. On the other hand, the maintenance of sequences in one chromosomal site and their appearance in a second site characterizes transposition[45]. If amplification is associated with transposition of sequences in T1, the transposed sequence must be at least 300 kb, the size of the inserted sequences! Moreover, since *Drosophila* contains elements capable of transposing sequences of this length[46], the involvement of large-scale DNA transposition in gene amplification deserves further consideration.

We thank Judy Meinkoth, Walter Eckhart, Ron Evans, Suzanne Bourgeois and Marguerite Vogt for suggestions, Valerie Jameson for manuscript preparation, and Lee Hartwell and George Stark for valuable discussions leading respectively to the ideas that DNA insertion could create a hyperamplifiable region and that DNA transposition could be involved in gene amplification.

Close similarity of epidermal growth factor receptor and v-*erb-B* oncogene protein sequences

J. Downward*, Y. Yarden†, E. Mayes*, G. Scrace*, N. Totty*, P. Stockwell*§, A. Ullrich‡, J. Schlessinger† & M. D. Waterfield*

*Each of six peptides derived from the human epidermal growth factor (EGF) receptor very closely matches a part of the deduced sequence of the v-*erb-B *transforming protein of avian erythroblastosis virus (AEV). In all, the peptides contain 83 amino acid residues, 74 of which are shared with v-*erb-B*. The AEV progenitor may have acquired the cellular gene sequences of a truncated EGF receptor (or closely related protein) lacking the external EGF-binding domain but retaining the transmembrane domain and a domain involved in stimulating cell proliferation. Transformation of cells by AEV may result, in part, from the inappropriate acquisition of a truncated EGF receptor from the c-*erb-B *gene.*

REGULATION of the proliferation of cells in culture can be influenced by a number of mitogens including a series of polypeptide growth factors which, acting alone or synergistically with other mitogens, can induce DNA synthesis and proliferation of specific target cells (for recent reviews see ref. 1). Epidermal growth factor (EGF) and platelet-derived growth factor (PDGF) are probably the best characterized growth factors: the precise function of these polypeptides *in vivo* is, however, unclear. EGF may have a role in cell proliferation and differentiation since it will induce early eyelid opening and incisor development in new born mice[2]; PDGF on the other hand, which is released from platelets during blood clot formation at wound sites, may have a role in repair processes[3]. These and other growth factors *in vitro* can trigger a variety of morphological and biochemical changes that resemble those characteristic of transformed cells, and have also been implicated in the abnormal regulation of proliferation shown by transformed and tumour-derived cell lines (reviewed in refs 4 and 5). Thus it has been suggested that transformed cells may both synthesise and respond to growth factors and consequently proliferate independently through 'autocrine' secretion[6]. Direct support for such an autocrine role for aberrantly expressed growth factors in the control of abnormal cell proliferation came recently from the discovery that the putative transforming protein ($p28^{sis}$) of simian sarcoma virus (SSV) is structurally related to the growth factor PDGF[7–9] and can also function like PDGF as a growth factor for cells in culture[10]. Other growth factors produced by transformed cells such as insulin-like growth factor (IGF)[11,12], fibroblast-derived growth factor[13,14] and the transforming growth factors (TGFs)[15–20], may also act as autocrine regulators of proliferation. Besides the specificity mediated by regulation of the production of growth factors, cellular specificity could also be controlled at several other levels—the most obvious being by binding of ligand to specific receptors present only on target cells. In addition the binding of one growth factor to its specific receptor can also alter the affinity of another growth factor for its receptor (for example, PDGF and the EGF receptor[21,22]). Conversely two growth factors may, as appears to be the case with αTGFs and EGF, bind to the same receptor[23,24].

It is clear that binding of different growth factors to their specific receptors can induce a cascade of biochemical events including rapid changes in ion movements and intracellular *p*H, stimulation of tyrosine specific protein kinases and several other changes which can culminate in DNA synthesis and proliferation of certain target cells[1,4–6]. It seems likely that at least in the case of the EGF receptor the primary function of EGF may be to induce cross-linking or conformational changes of receptors, and that following such an activation step, all the 'information' necessary for triggering a proliferative response may reside in the receptor itself (see ref. 1). One known function intrinsic to the EGF receptor is its ability to phosphorylate tyrosine residues[25–28], a property shared with five of the putative transforming proteins of the family of retroviruses whose oncogenes are structurally related to *src* but not by two others, the proteins encoded by *mos* and *erb-B*[29]. At present this tyrosine kinase activity provides the only functional activity associated with the oncogenes of this subset of retroviruses.

Here we report amino acid sequence analysis of six distinct peptides from human EGF receptors isolated by monoclonal immunoaffinity purification from A431 cells and placenta, and show that 74 out of 83 of the residues sequenced are identical to those of the transforming protein encoded by the v-*erb-B* oncogene of avian erythroblastosis virus (AEV)[30]. The amino acid sequences of several other peptides purified from the EGF receptor could not be aligned with sequences of the v-*erb-B* protein suggesting that AEV has acquired cellular sequences encoding only a portion of the avian EGF receptor. Several lines of evidence suggest that the v-*erb-B* oncogene encodes only the transmembrane region of the EGF receptor and the domain associated with the tyrosine kinase activity. These results suggest a hypothesis that the *src* related subset of oncogenes, which includes v-*erb-B*, may be derived from cellular sequences which encode growth factor receptors and produce transformation through expression of uncontrolled receptor functions.

Purification of EGF receptor

EGF receptors can be detected in a variety of cells either by measurement of EGF binding (reviewed in ref. 31), by cross-linking of labelled EGF to its receptor (reviewed in ref. 32) or by using monoclonal antibodies[33–38]. In this study the receptor has been purified from two sources: the human epidermoid carcinoma cell line A431, which expresses about 50 times more receptors than the majority of other cells[39,40], and human placenta[41] which is a readily available normal tissue. The recent isolation of monoclonal antibodies which recognize the human EGF receptor[34,38] has made it possible to use immunoaffinity chromatography for receptor purification. Here we compare by peptide mapping EGF receptor protein purified by either immunoaffinity or EGF affinity chromatography[26] and also compare the structures of the A431 and placental receptors.

A radioimmunoassay (RIA) which uses a monoclonal antibody (R1) has been used to quantitate various preparative

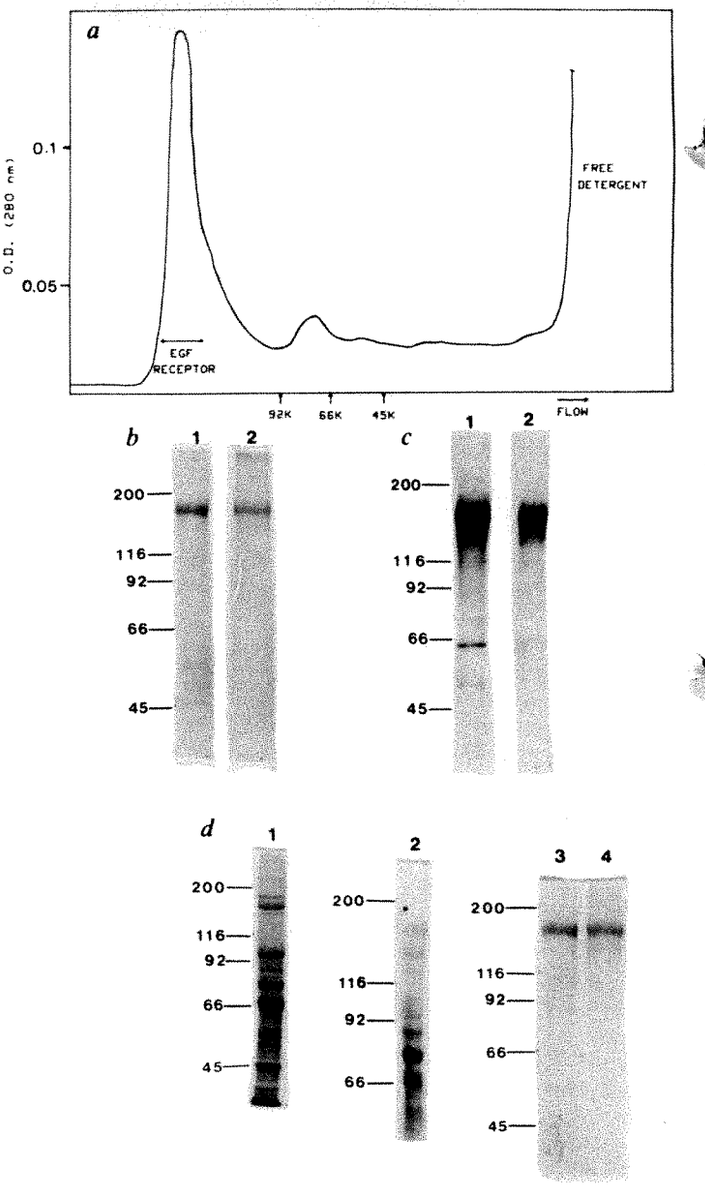

Fig. 1 Immunopurification of EGF receptor from A431 cells and human placenta. ***a***, Purification by gel permeation. Reduced and alkylated receptor was purified on a TSK4000 column (0.7 × 60 cm, LKB) using 0.1 M potassium dihydrogen phosphate buffer *p*H 4.5 containing 6 M guanidine HCl at a flow rate of 0.5 ml min^{-1} (ref. 43). The absorbance of the eluate was monitored at 280 nm (molecular weights of protein standards are indicated) and 0.25 ml fractions were collected. Fractions containing EGF receptor were dialysed against 10 mM ammonium bicarbonate. Panels ***b–d*** show 7% polyacrylamide SDS gels[72] used to monitor purification (MW × 10^{-3} of protein standards are indicated). *b*, R1 purified A431 EGF receptor: track 1, *p*H 3 eluate from R1 immunoaffinity matrix; track 2, eluate from the TSK4000 column. *c*, 29–1purified A431 EGF receptor: track 1, *p*H 3 eluate from 29–1 immunoaffinity matrix; track 2, eluate from SDS preparative gel electrophoresis. *d*, Lectin and R1 purified placental EGF receptor: track 1, placental vesicles; track 2, eluate from lectin affinity matrix; track 3, eluate from R1 immunoaffinity matrix; track 4, eluate from the TSK4000 column.

Methods: Approximately 2×10^9 A431 cells were washed in calcium and magnesium free phosphate-buffered saline (PBS) and solubilized in 400 ml lysis buffer (50 mM Tris-HCl *p*H 7.4, 0.15 M NaCl, 5 mM EGTA, 0.1% bovine serum albumin, 1% NP40, 25 mM benzamidine, 0.2 mM PMSF, 10 μg ml^{-1} leupeptin). After filtration through muslin the lysate was adjusted to *p*H 8.5 and centrifuged at 100,000g_{max} for 30 min. The supernatant was incubated for 2 h at 4 °C with immunoaffinity matrix, which consisted of 15 mg of monoclonal antibody R1[34] coupled to 15 ml of Affi-Gel 10 (BioRad). Unbound lysate was removed by suction through a 0.4 micron filter. The matrix was then washed by gentle agitation and filtration with 500 ml PBS, containing 0.65 M NaCl and 0.1% NP40, followed by 500 ml PBS, containing 0.1% NP40. The EGF receptor was eluted by gentle agitation and filtration of the matrix with 2 × 10 ml aliquots of 50 mM sodium citrate *p*H 3, containing 0.05% NP40 for 10 min each. Eluates were adjusted to *p*H 7. The yield of receptor was approximately 250 μg, measured by Bradford technique[70] or by amino acid analysis after gel permeation HPLC (see below). Alternatively EGF receptor was purified from A431 cells using monoclonal antibody 29-1[38] coupled to CNBr-activated Sepharose (Pharmacia) at 5–10 mg ml^{-1}. The purification procedure used was similar to that described for the R1 immunoaffinity matrix except that the EGF receptor was phosphorylated whilst bound to the matrix with 50 μCi [$\gamma-^{32}$P]ATP (3,000 Ci $mmol^{-1}$, Amersham International) in the presence of 3 mM $MnCl_2$. Eluted receptor was further purified by preparative SDS gel electrophoresis, followed by dialysis against 10% methanol at 4 °C. For purification of placental EGF receptor, vesicles were made from syncytiotrophoblast microvilli by a modification of the method of Smith *et al.*[71], using 2 mM EGTA in all buffers. Vesicles were solubilized by addition of an equal volume of 100 mM HEPES *p*H 7.4, 0.15 M NaCl and 5% Triton X-100. After centrifuging at 100,000g_{max} for 30 min the supernatant was incubated for 1 h at room temperature with 200 mg wheat germ agglutinin coupled to 10 g of Affi-Gel (BioRad). The lectin matrix was washed by filtration through a 0.4 μm filter with 100 ml of PBS, containing 0.1% Triton X-100. Bound protein was eluted by agitation and filtration with 2 × 15 ml aliquots of 0.25 M *N*-acetylglucosamine in 10 mM HEPES *p*H 7.4, 0.1% Triton X-100 for 15 min each. The eluate was incubated with R1 immuno-affinity matrix (15 mg antibody per placenta) for 2 h at 20 °C, followed by extensive washing and elution as described above for receptor purification from A431 cells. The yield of EGF receptor per placenta was 25 μg, measured by Bradford technique[70] and amino acid analysis after gel permeation HPLC (see below). Solutions containing EGF receptor were lyophilized and resuspended in 0.5 M Tris-HCl *p*H 8.5, 6 M guanidine hydrochloride (Schwarz-Mann) at 0.5–1 mg ml^{-1}. After incubation at 37 °C for 16 h with 10 mM dithiothreitol, cysteine residues were alkylated with ^{14}C-iodacetamide (40–60 mCi $mmol^{-1}$, Amersham International) as described previously[44].

techniques[42]. Receptors from A431 cells and placenta were both found to be unstable in detergent-solubilized whole cell or tissue lysates, perhaps as a result of the release of proteases from the cellular lysosomal compartment. This problem was overcome for placenta by the preparation of syncytiotrophoblast microvillus plasma membranes and as a result a 50-fold purification with a 30% yield of receptor was achieved. Unfortunately, with A431 cells the yield of receptor in plasma membrane preparations was impractically low. However, quantitative studies with the receptor RIA showed that rapid adjustment of the lysate *p*H to 8.5 followed by fast immunoaffinity chromatography of whole cell lysates minimised the effects of the proteases.

Placental membranes were solubilized and glycoproteins separated by wheat germ agglutinin (WGA) affinity chromatography to achieve a partial purification. EGF receptor was then purified from the placental glycoprotein fraction or from A431 cell lysates by immunoaffinity chromatography on either monoclonal antibodies R1[34] or 29-1[38] immobilised on agarose or Sepharose respectively. Nonspecifically bound protein was removed by washing the columns with a high salt buffer and the receptor was eluted at *p*H 3. The receptors were further purified either on preparative SDS-polyacrylamide gels or by gel permeation HPLC in guanidine solutions[43]. Details of the methods used and the yields of purified receptors are given in the legend to Fig. 1. Since the EGF binding and protein kinase activity were partially destroyed during purification, receptor was also purified by EGF affinity chromatography[26]. Comparative HPLC tryptic peptide maps were then carried out to establish the purity and structural similarity of receptor prepared by immunoaffinity chromatography from A431 cells and placental tissue. The peptide maps of the receptors (Fig. 2) showed that the elution profiles of the receptor tryptic peptides were very

similar whether receptor was purified by EGF affinity or by immunoaffinity chromatography; from A431 cells or from placental tissue.

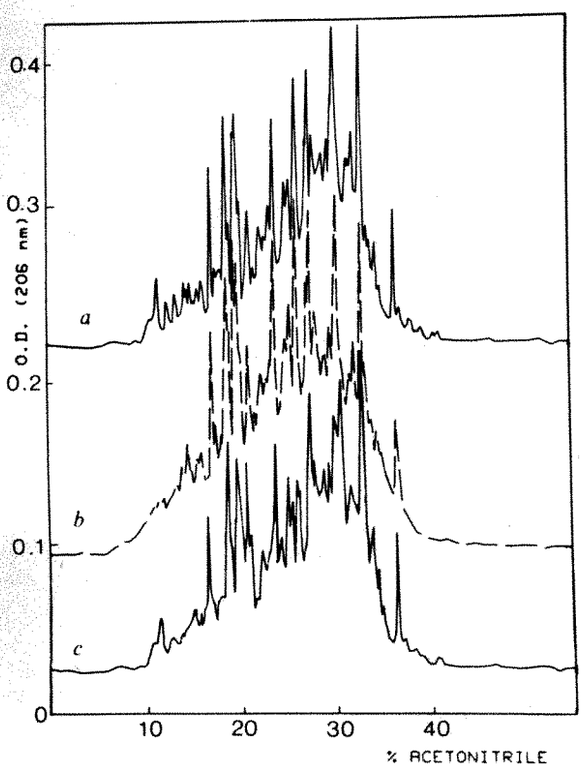

Fig. 2 Reverse phase HPLC analysis of tryptic peptides from EGF receptor purified by three different affinity methods. ***a***, Immunoaffinity purified A431 receptor. EGF receptor was purified from A431 cells using the monoclonal antibody R1 and gel permeation chromatography in guanidine solutions as described in Fig. 1. Pooled fractions containing the 175,000 MW EGF receptor were dialysed against 10 mM ammonium bicarbonate, lyophilized and resuspended in 500 μl of 100 mM ammonium bicarbonate, 10 mM $CaCl_2$. TPCK treated trypsin (Sigma) was then added (100:1, receptor:trypsin, w/w). This mixture was incubated at 37 °C for 12 h, a further identical aliquot of trypsin added and the incubation continued for another 12 h. Peptides were then loaded directly onto a Synchropak RPP C18 reverse phase HPLC column (Synchrom, Linden, Indiana, 4.6×75 mm) equilibrated in 0.1% trifluoroacetic acid (TFA, Rathburn, Scotland) and a gradient from zero to 45% acetonitrile was run over 45 min at 1 ml min^{-1} and 1 ml fractions collected[46]. A Waters HPLC system including two M6000 A pumps, a U6K manual injector and a 660 solvent programmer with 2 LKB 2138 Uvicord S absorbance detectors with filters at 206 nm and 280 nm was used[45]. The figure shows the optical density of the eluate at 206 nm plotted against acetonitrile concentration. ***b***, EGF affinity purified receptor. EGF receptor was purified from A431 cells using wheat germ agglutinin affinity chromatography followed by EGF affinity chromatography[26]. A431 cells were lysed as described in the legend to Fig. 1. Purification of this lysate on the WGA affinity column was identical to that described for the placental preparation (Fig. 1). The eluate from the WGA affinity column was mixed with 5 ml of Affi-Gel 10 (BioRad) having 1 mg of bound EGF. The mixture was tumbled for 4 h at room temperature before washing the immobilized EGF receptor with 100 ml of PBS, 0.1% Triton X-100. Receptor was then eluted with 10 mM ethanolamine, *p*H 9.7, 0.1% Triton X-100. This eluate was further purified on a TSK4000 gel permeation column as described in Fig. 1. Fractions containing EGF receptor were pooled, dialysed, lyophilized and trypsinized as described for *a* above. The resulting tryptic peptides were separated by reverse phase HPLC under identical conditions to those described above. ***c***, Immunoaffinity purified placental receptor. EGF receptor was purified from fresh term human placenta as described in the legend to Fig. 1. The receptor was digested with trypsin and peptides separated by reverse phase HPLC as described above. Peptides in the column breakthrough are not shown.

Amino acid sequence

Receptor was purified by immunoaffinity chromatography followed by either preparative SDS gel electrophoresis or by gel permeation HPLC in guanidine[43] after reduction and alkylation[44] to cleave disulphide bonds (see Fig. 1). Purified receptor was then digested with trypsin or cyanogen bromide (see Figs 2 and 3) and peptides were separated by preparative reverse phase HPLC[45,46] (Fig. 3). Amino acid sequences were determined with a gas phase sequencer constructed and operated as described by Hewick *et al.*[47], using the analytical techniques for the quantitation of phenyl thiohydantoin (PTH) amino acids described by M.D.W. *et al.*[48]. The quantitative data for analysis of six peptides are shown in Fig. 4.

The amino acid sequences of 14 different peptides from the human EGF receptor, three from placenta and 11 from A431 cells, were compared with sequences in an oncogene sequence data base (set up at ICRF using published sequences) by the rapid search techniques of Wilbur and Lipman[49]. A remarkable identity was found between the sequences of six of these peptides and regions of the predicted sequence of the putative transforming protein v-*erb-B* of the AEV-H isolate of avian erythroblastosis virus[30]. Of the 83 amino acid residues from these six sequenced peptides, 74 residues were identical and four showed conservative substitutions when they were aligned with the v-*erb-B* encoded protein sequence, as shown in Fig. 5. Peptide 1 was located near the amino terminus of the v-*erb-B* protein (residues 107–125) and peptide 6 at the carboxy terminus (residues 583–599), with the other four peptides in between. It was not necessary to introduce any deletions or insertions into the sequence to optimize the alignments.

Although the full extent of the similarity between the v-*erb-B* protein and EGF receptor sequences is not revealed by these limited sequence studies, it is likely that the region of the v-*erb-B* protein from residue 107 to the carboxy terminus has extensive homology to the EGF receptor. The degree of identity observed is very high and since the v-*erb-B* sequences of AEV were presumably of avian origin[30], while the EGF receptor sequences were from the human protein, it is likely that the v-*erb-B* sequences were mainly acquired by AEV from those cellular sequences which encode the avian EGF receptor. This suggests that the c-*erb-B* locus encodes the EGF receptor in humans and birds.

The amino acid sequence of 8 of the 14 peptides purified from the EGF receptor (data not shown) could not be aligned with the predicted sequences of the v-*erb-B* protein. Since the polypeptide backbone of the EGF receptor glycoprotein is thought to be about 1,250 amino acids[50] and the predicted v-*erb-B* protein is only 604 amino acids[30] the most likely explanation is that these eight peptides are encoded by a region of c-*erb-B* which has not been acquired by AEV. This could have arisen by a recombination event(s) which resulted in only a part of the EGF receptor coding sequences being acquired by AEV. Although it is possible that DNA rearrangements of receptor coding sequences occur similar to those found with immunoglobulins, it is more likely that differential mRNA splicing would be involved in any such recombination events. It has been shown that avian cells contain two c-*erb-B* related transcripts[51] and studies of the biosynthesis of the EGF receptor in A431 cells suggest that both a normal and a truncated receptor may be synthesized[50]. Alternatively two or more loci encoding polypeptides having very similar amino acid sequences to those of the EGF receptor exist on chromosome 7 (see below). An example of two closely related putative transforming proteins with tyrosine kinase activity has been reported in studies of the avian retroviruses Rous sarcoma virus (RSV) and Yamaguchi Y63[52]. The predicted amino acid sequences of the proteins encoded by the *src* and *yes* oncogenes were shown to have 82% match over a region covering 436 amino acid residues (while the DNA sequences showed only 31% overall match) and presumably the chicken genome contains both *src* and *yes* proto-oncogenes encoding separate proteins sharing extensive regions of sequence. It is not known whether human c-*src* and c-*yes*

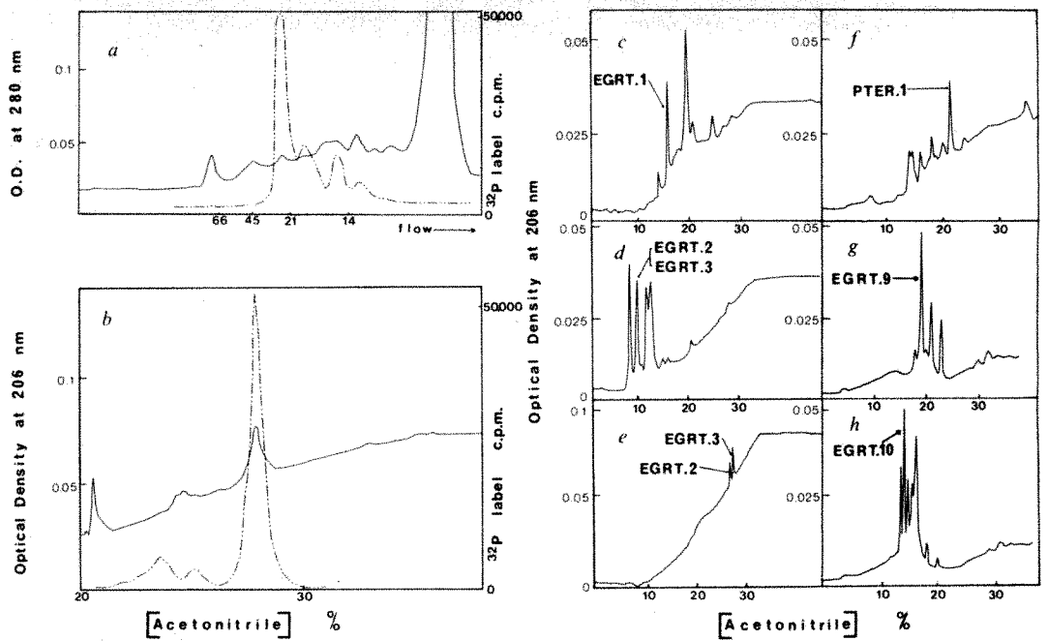

Fig. 3 Purification of peptides from EGF receptor for sequence analysis. ***a***, Cyanogen bromide cleavage and fractionation of peptides by size. ^{32}P-labelled EGF receptor in ammonium bicarbonate solution was lyophilized and resuspended in 70% formic acid. Cyanogen bromide was added under nitrogen, the tube sealed and incubated in the dark at room temperature for 24 h. Formic acid and excess cyanogen bromide were removed by repeated cycles of drying and resuspension in water using a Speed-vac concentrator (Savant). The dry sample was resuspended in 0.1 M potassium dihydrogen phosphate buffer, *p*H 4.5 containing 6 M guanidine HCl and the peptides separated by gel permeation HPLC on a TSK3000 column (0.7×60 cm, LKB) equilibrated in the same buffer at a flow rate of 0.3 ml min^{-1} [43]. The optical density of the eluate was monitored at 280 nm (– – –) and 0.3 ml fractions collected and counted for ^{32}P (– · · –). Molecular weights $\times 10^{-3}$ of protein standards are indicated. ***b***, Subfractionation of cyanogen bromide fragments. The peak from the TSK3000 column containing most of the ^{32}P-label was pooled and dialysed against 10 mM ammonium bicarbonate. After lyophilization, the sample was redissolved in 0.1% TFA and peptides separated by reverse phase HPLC on a Synchropak RPP C18 column (see Fig. 2) equilibrated in 0.1% TFA, 10% acetonitrile[45,46]. A gradient of 10–40% acetonitrile run over 60 min was used to elute peptides, at a flow rate of 1 ml min^{-1}. The optical density of the eluate was monitored at 206 nm (– –) and 1 ml fractions were collected and counted for ^{32}P-label (– · · –). ***c***, The fractions corresponding to 23–24% acetonitrile from the HPLC analysis of A431 EGF receptor tryptic peptides were pooled. Peptides were further purified by reverse-phase HPLC on a Synchropak RPP C18 column equilibrated in 10 mM ammonium acetate buffer *p*H 6.5. A linear gradient of 0–45% acetonitrile was run over 45 min at a flow rate of 1 ml min^{-1}. The optical density of the eluate was monitored at 206 nm and 0.5 ml fractions collected. ***d***, The fractions corresponding to 19–20% acetonitrile from the reverse-phase HPLC purification of A431 EGF receptor tryptic peptides (Fig. 2*a*) were pooled. A linear gradient of 0–45% acetonitrile over 45 min was used to elute peptides, at a flow rate of 1 ml min^{-1}. The optical density of the eluate was monitored at 206 nm and 0.2 ml fractions collected. ***f***, The fractions corresponding to 27–28% acetonitrile concentration from the reverse-phase HPLC analysis of placental EGF receptor tryptic peptides (Fig. 2*c*) were pooled. Peptides were subfractionated as described in *c*. ***g***, The fractions corresponding to 25–26% acetonitrile from the reverse-phase HPLC purification of A431 EGF receptor tryptic peptides (Fig. 2*a*) were pooled. Peptides were subfractionated as described in *c*. ***h***, The fractions corresponding to 21–22% acetonitrile from the reverse-phase HPLC analysis of A431 EGF receptor tryptic peptides (Fig. 2*a*) were pooled. Peptides were subfractionated as described in *c*.

are encoded by closely linked loci. However, analysis of human-mouse somatic cell hybrids has shown that the locus encoding the human EGF receptor is on chromosome 7 (7p13-7q22)[53–55] and that for c-*erb-B* is in the same region of this chromosome (7pter–7q22)[56]. This observation supports the concept that the c-*erb-B* locus encodes the human EGF receptor or is very closely linked to that encoding the EGF receptor.

Analysis of EGF receptor mRNA transcripts found in A431 and avian cells by cDNA cloning is currently in progress which, together with analysis of human and avian genomic clones, should define the relationship of c-*erb-B* and the locus encoding the EGF receptor (A.U. *et al.*, in preparation).

Shared regions of sequence

Several lines of evidence suggest that the EGF receptor protein can be divided into three major domains; an EGF binding domain which lies external to the plasma membrane, a transmembrane domain and a cytoplasmic kinase domain having both the kinase activity and the autophosphorylation sites.

Investigations of receptor biosynthesis show that the A431 receptor is a glycoprotein of apparent molecular weight (MW) 175,000, having ~37,000 MW of oligosaccharide side chains with a polypeptide backbone of ~138,000 MW (~1,250 amino acids). Limited proteolysis of the mature receptor suggests that the domain external to the plasma membrane which contains the oligosaccharide side chains and the antigenic sites for monoclonal R1 has a MW of ~115,000 (~710 amino acids)[50]. Several studies show that the EGF binding site is external to the plasma membrane[25,31,32].

The location of the tyrosine kinase enzymatic activity and the autophosphorylation sites on the cytoplasmic domain is supported by studies made using A431 and placental membrane vesicles (J.D. and M.D.W., in preparation). These show that EGF stimulated tyrosine kinase activity directed towards artificial substrates or towards autophosphorylation sites is significantly activated only after membrane permeabilization. Furthermore, the tyrosine kinase activity can phosphorylate pp36—a protein known to be located at the cytoplasmic side of the membrane[57]. In addition recent studies show that antibodies raised against synthetic peptides from pp60$^{v\text{-}src}$ recognize antigenic sites on the human EGF receptor that are from regions of sequence homologous to the sequence of v-*erb-B* (see below). These sites are only accessible in permeabilized cells (J.S. *et al.*, in preparation).

Autophosphorylation sites are located within peptide 5 (EGRC.1), a 20,000 MW cyanogen bromide fragment which contains 70% of the ^{32}P-label present in the autophosphorylated receptor (see Fig. 3*a*). Although the precise location of the residues phosphorylated has not been determined a consensus tyrosine phosphorylation sequence[58] was found near the amino

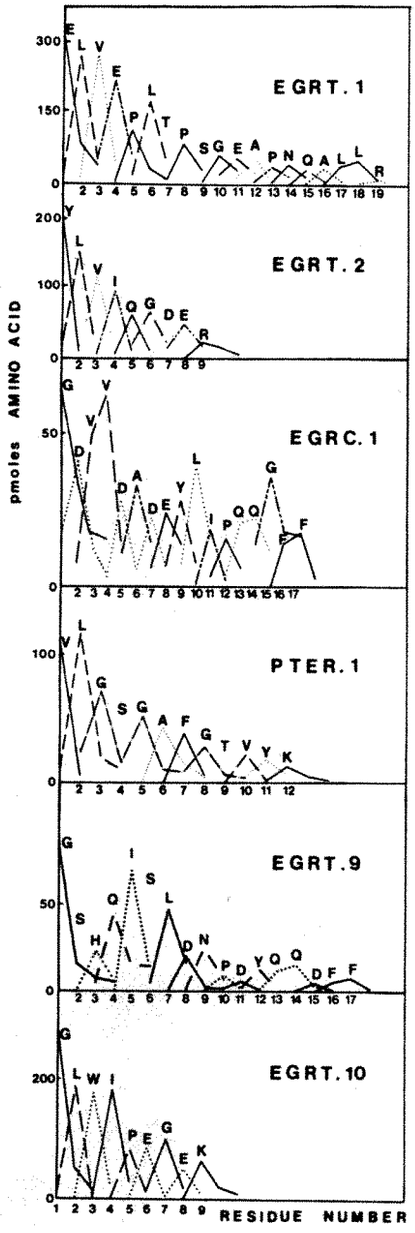

Fig. 4 Sequence analysis of peptides from the EGF receptor. Peptides were purified as described in Fig. 3. Sequence determination of each peptide was carried out using a gas phase sequencer assembled and operated as described by Hewick *et al.*[47]. PTH amino acids were analysed by HPLC using a Zorbax C8 column (4.6×150 mm, Dupont) at 43 °C with a linear gradient over 8 min of acetonitrile from 24% to 38% at a flow rate of 2 ml min^{-1} using 9 mM sodium acetate buffer *p*H 4.1[48]. A Waters HPLC system including two M6000 A pumps, a WISP autoinjector and system controller with a Beckman Model 160 detector was used. The recovery of PTH amino acids at each degradative cycle was measured using an integrative recorder (Waters Data module). The amounts of each peptide *analysed* (pmol) were measured by amino acid analysis (EGRT.1, 380; EGRT.2, 260; EGRC.1, 80; PTER.1, 145; EGRT.9, 100; EGRT.10, 325). The analysis for serine and threonine could not be accurately measured due to the presence of multiple peaks obtained during analysis of the PTH amino acids. The presence of these amino acids is thus indicated without quantitative data; these residues are assigned to the sequence using semi-quantitative recovery data based on peak heights rather than areas. Prior to loading peptides, fibre glass disks were treated with polybrene and glycylglycine and precycled for ten cycles. Each peptide was sequenced twice; on the second run of peptide EGRC.1 filters were treated with polybrene and cysteic acid and precycled ten times to clarify the assignment of an amino terminal glycine residue. However the background glycine at step 1 is still significant and this residue may be incorrect.

terminus of this peptide. Therefore we believe that the tyrosine phosphorylation sites lie within the cytoplasmic domain of the EGF receptor which is contained in the sequence shared with the v-*erb-B* protein.

Preliminary nucleotide sequence analysis (A.U. *et al.*, in preparation) of cDNA clones selected from a placental cDNA library using synthetic oligonucleotide probes synthesized on the basis of the receptor amino acid sequence shows that the predicted carboxyl terminus of the EGF receptor extends 32 amino acids from an amino acid equivalent to residue 601 (see Fig. 5) of the predicted v-*erb-B* protein sequence. This analysis when complete will show the precise size and sequence of the presumptive cytoplasmic domain of the EGF receptor. The approximate molecular weight of this domain would be 60,000 (or 545 amino acids) since that part which is external to the membrane is thought to have a molecular weight of 115,000 (see above)[50]. Thus the cytoplasmic domain would be predicted to be similar in size to that region of the v-*erb-B* protein which is carboxy terminal to a putative transmembrane sequence (see Fig. 5 and ref. 30) at residues 66–88. This carboxy terminal region of v-*erb-B* would have a molecular weight of 56,760 and would contain 516 amino acids.

The putative transmembrane sequence of the v-*erb-B* protein is not preceded by a signal sequence for membrane insertion. Nevertheless, immunofluorescence studies of AEV transformed cells show that the v-*erb-B* protein has antigenic sites external to the plasma membrane[59]. This external region probably corresponds to the 65 residue amino terminal section that precedes the putative transmembrane sequence and contains three asparagine residues which have the oligosaccharide attachment recognition sequence Asn-X-Ser or Thr. Some or all of these residues may be glycosylated since *in vitro* translation studies of mRNA from AEV infected cells show that post translational processing of nascent polypeptides occurs in the presence of membrane vesicles[59,60].

Together these studies suggest that the predicted v-*erb-B* transforming protein closely resembles the transmembrane region of the EGF receptor and the domain which is thought to be cytoplasmic. If the v-*erb-B* sequence was acquired from the gene encoding the EGF receptor then the v-*erb-B* protein represents a truncated receptor which lacks the EGF binding domain. It is particularly interesting that studies of EGF receptor biosynthesis in A431 cells have suggested that a polypeptide equivalent to the external domain of the receptor (of MW 115,000) is synthesized[50] in addition to the normal receptor. Further studies are necessary to understand the origin of this truncated receptor but the results show that defective receptors may be synthesized by this human tumour cell line.

Growth factors and transformation

Recently it has been shown that the transforming protein of simian sarcoma virus has a close structural and functional relationship to the growth factor PDGF[7–10] supporting the hypothesis that autocrine growth factor production may be involved in abnormal growth control and neoplasia. These observations together with those presented here illustrate two distinct but related mechanisms for subversion of normal growth regulation. In the case of SSV the oncogene encodes a growth factor which can act as a mitogen for target cells having PDGF receptors[10]. AEV on the other hand appears to utilize a different mechanism where a part of a growth factor receptor which is thought to be involved in transducing the EGF signal may be expressed in transformed cells. The absence of the EGF binding domain might remove the control generated by ligand binding and the result could be the continuous generation of a signal equivalent to that produced by EGF, causing cells to proliferate rapidly. How this could result in the block in differentiation observed in AEV infected haemopoietic cells[61] is unclear. However, EGF has been shown to promote proliferation while inhibiting terminal differentiation of human keratinocytes[31].

The ES4 strain of AEV has two oncogenes v-*erb-A* and v-*erb-B*, which are thought to encode proteins of MWs 75,000

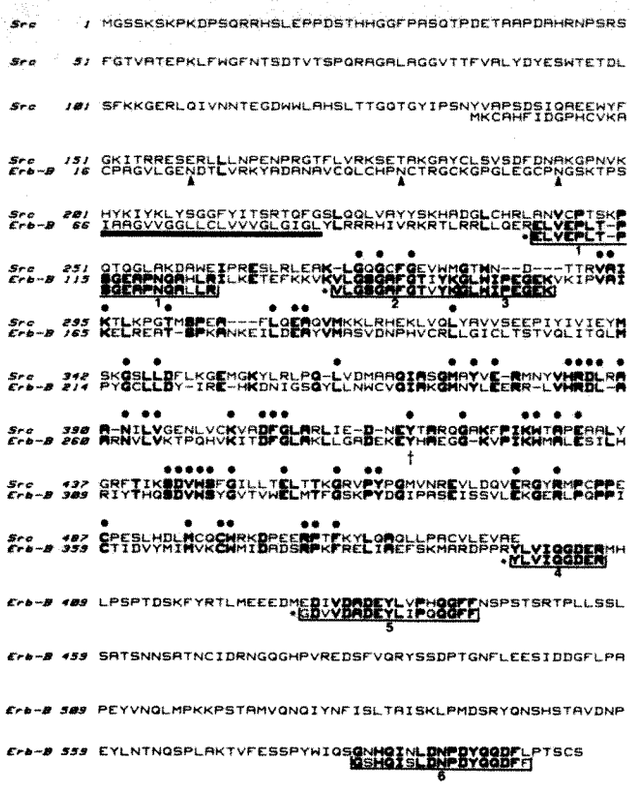

Fig. 5 The relationship between the amino acid sequences of the EGF receptor peptides and the predicted amino acid sequences of the putative transforming proteins of v-*src* and v-*erb-B*. The predicted amino acid sequence of the v-*src* gene product (pp60$^{v\text{-}src}$) is translated from the presumptive initiation codon at nucleotide 7,129 of the Prague C strain of Rous sarcoma virus[73]. The predicted amino acid sequence of the v-*erb-B* gene product is translated from the presumptive initiation codon at nucleotide 155 of the v-*erb-B* gene in AEV-H[30]. The partial amino acid sequences of the six peptides purified from the EGF receptor are shown (underlined): 1, EGRT.1; 2, PTER.1; 3, EGRT.10; 4, EGRT.2; 5, EGRC.1; 6, EGRT.9. Letters in bold type represent residues shared by pp60$^{v\text{-}src}$ and the v-*erb-B* protein. Residues shared by the EGF receptor peptides and v-*erb-B* protein or pp60$^{v\text{-}src}$ are in bold type. ● indicates amino acid residues, which are common to the putative transforming proteins of v-*erb-B*, v-*src*, v-*fes*, v-*fps*, v-*yes* and v-*abl*. †, Phosphoacceptor tyrosine of pp60$^{v\text{-}src}$[74]. ▲, Possible *N*-linked glycosylation sites at the amino terminus of the v-*erb-B* protein. ▬ indicates the putative transmembrane sequence in the v-*erb-B* protein. *, Amino acid residues which would be expected to produce enzymatic or cyanogen bromide cleavages to generate the observed peptides. Numbers to the left of the sequences are residue numbers taking the presumptive initiation methionine as 1 in both cases. Sequences were aligned using a computer program[75] to optimize match.

and 65,000 respectively (for a recent review see ref. 62). Cells transformed by AEV *in vitro* and *in vivo* have the properties of erythroblasts which are late erythroid progenitors, although the target cells themselves may be earlier erythroid precursor cells. AEV can also transform fibroblasts and induce sarcomas. Evidence from deletion mutants[63] and from an isolate (AEV-H[30]) which lacks the v-*erb-A* gene suggests that the v-*erb-B* gene alone can induce transformation. This is supported by studies which show that RAV-1, a leucosis virus which has no oncogene, can activate the c-*erb-B* gene by a promoter insertion mechanism[64] perhaps similar to that presently being unravelled for c-*myc* activation[65–67]. It is possible that RAV-1 could induce expression of a normal receptor or a truncated receptor. EGF receptors have not generally been detected on haemopoietic cells by EGF binding studies but since these studies are limited in scope and sensitivity a more rigorous survey is needed before conclusions about normal receptor expression in different haemopoietic cell types can be made. Although many normal cells express 10–100,000 EGF receptors[31] only very low levels of c-*erb-B* transcripts have been found in normal chicken fibroblasts[51]. However a recent study of normal and neoplastic human lymphocytes suggests that both types of cells contain c-*erb-B* related transcripts. Clearly more detailed studies will be necessary to search for normal or altered c-*erb-B* or v-*erb-B* transcripts in normal, neoplastic or AEV transformed cells.

Previous reports have shown that the predicted amino acid sequences of the putative viral transforming proteins encoded by the oncogenes *erb-B*, *src*, *yes*, *fes*, *fps*, *mos* and *abl* show regions of similarity, implying homology[29,30,69]. In the case of *src*, *yes*, *fes*, *fps* and *abl* the putative transforming proteins have been shown to have tyrosine kinase activity (reviewed in ref. 29) but as yet those encoded by *erb-B*[30] and *mos* have not. Since the receptors for EGF and αTGF, PDGF, insulin and IGF-I also have associated tyrosine kinases, the structural relationship between the v-*erb-B* transforming protein and the EGF receptor observed here, suggests that other oncogenes from this subset of retroviruses could be derived in part from sequences encoding these or other growth factor receptors. Alternatively the other oncogenes in this group may be derived from sequences which encode proteins having a less direct functional relationship to the EGF and other receptors. Further study will clarify the precise function of growth factors, their receptors and *src* related oncogenes in normal and malignant growth.

M.D.W. thanks B. Ozanne and E. Rozengurt for introducing him to the field of study involving growth factors and their receptors. We acknowledge P. Parker, P. Stroobant, H. S. Earp and M. Fried for helpful discussions and advice, W. Gullick for help with receptor quantitation techniques and P. Bennett and R. Philp for technical assistance. We also thank W. J. Wilbur and D. J. Lipman for computer programs and N. Teich and the ICRF Computer Unit for their help. M.D.W. thanks S. J. for continued support. We are indebted to Queen Charlotte's Hospital and to E. J. Owen for help in providing placental tissue. This work was supported in part by grants from the USNIH (CA 25820) (J.S.) and from the US–Israel Binational Science Foundation (J.S.).

Interstellar scintillation and ultra-low-frequency gravitational wave observations

J. W. Armstrong

Jet Propulsion Laboratory, Mail Stop 238–737,
4800 Oak Grove Drive, Pasadena, California 91109, USA

High-precision pulsar timing measurements have been used[1–4] to set upper limits on the flux of ultra-long period ($T \geq 3$ years) stochastic gravitational waves. The data used to produce the current limits appear to be limited by timing noise[5,6] that is intrinsic to the pulsars. Recently, however, there have been very low noise timing observations[7] of the 1.5-millisecond pulsar[8]. This suggests that significant sensitivity improvements in searches for ultra-low-frequency (ULF) gravitational waves may be possible. Here the effects of a heretofore secondary noise source—phase scintillations caused by interstellar electron density fluctuations—are calculated and the prospects for improved ULF gravitational wave measurements using pulsar timing are discussed.

The observed quantity in these experiments is a time series of the difference between the observed and expected pulse arrival times. The time series contains contributions from intrinsic timing noise, gravitational radiation (buffeting of the pulsar and Earth at different epochs), estimation error due to finite signal to noise ratio, and interstellar phase scintillation (ISS). The ISS contribution arises due to dispersion measure fluctuations as irregular clouds of electrons rearrange and drift across the pulsar–Earth line[9,10]. To estimate the contribution to pulsar timing noise measurements a model of the interstellar turbulence spectrum and the relevant propagation theory are required. Observations[10–12] are consistent with an isotropic three-dimensional electron density power spectrum, $P_{3N}(q)$, of the form $P_{3N}(q) = C_N^2 q^{-11/3}$ where q is the spatial wavenumber. The 'structure constant' C_N^2 is typically 10^{-5} to 10^{-2} m$^{-6.67}$ (ref. 11), but can be estimated for the the line-of-sight to the 1.5-millisecond pulsar from the measured frequency correlation bandwidth in the dynamic spectrum[8] or the measured temporal broadening of pulses[13]. Using the observed correlation bandwidth (≈1 MHz at $\lambda = 0.21$ m observing wavelength) and the observed pulse broadening (73 μs at $\lambda = 0.94$ m), C_N^2 can be estimated using equations 31 and 41 of ref. 10. For homogeneous turbulence along the pulsar–Earth path of 5 kpc (ref. 14), those observations yield identical estimates of $C_N^2 = 8 \times 10^{-5}$ m$^{-6.67}$. Because both decorrelation bandwidth and pulse broadening are diffraction phenomena, those observables are dominated by density fluctuations on scales of the Fresnel zone size (~10^{10} m). However, direct and indirect measurements of P_{3N} on the 10^{11}–10^{13} m scales relevant to ULF gravitational wave measurements are consistent with an extrapolation of the power at smaller scales; the inferred shape and level of the spectrum on these scales is in fairly good agreement with $P_{3N}(q) = (10^{-4}\,\mathrm{m}^{-6.67})\, q^{-11/3}$ (ref. 11).

For gravitational wave searches, noise sources can be characterized either by the power spectrum of fractional frequency fluctuations[2,15] or the Allan variance[16] of the frequency time series[17]. The spectrum of fractional frequency fluctuations caused by ISS, $S_y(f)$, can be calculated in three steps. First, ignoring diffraction at the relatively large scales of interest here, the two-dimensional spatial spectrum of phase on the Earth's surface is given by (ref. 9)

$$P_{2\phi}(\kappa) = 2\pi\lambda^2 r_e^2 z C_N^2 \kappa^{-11/3} \quad (1)$$

where κ is the two-dimensional wavenumber, λ is the observing wavelength, r_e is the classical electron radius, and z is the pulsar–Earth distance. Second, to convert to a temporal spectrum of phase fluctuations it is assumed that the phase scintillation pattern is 'frozen' in a reference frame that moves with a uniform velocity v transverse to the pulsar–Earth line. Integrating over the wavenumber component associated with the direction perpendicular to the velocity vector then gives the temporal phase spectrum. Finally, noting that frequency is the temporal derivative of phase, the 'derivative theorem' for Fourier transforms[18] can be applied to obtain $S_y(f)$. The result is:

$$S_y(f) = \pi^{-1/6} 2^{-2/3} v^{5/3} \lambda^4 c^{-2} z C_N^2 r_e^2 [\Gamma(4/3)/\Gamma(11/6)]\, f^{-2/3} \quad (2)$$

where c is the speed of light, v is the velocity of the pattern, Γ is the gamma function and f is the temporal frequency.

Equation (2) can be used to predict ISS noise for ULF gravitational wave observations. Figure 1 shows the current observational limits to a ULF gravitational wave background[2–4], the envelope of stochastic gravitational wave spectra having closure density[19], and plots of equation (2) evaluated with the following parameters: $\lambda = 0.21$ m and 0.06 m, $z = 5$ kpc, $C_N^2 = 8 \times 10^{-5}$ m$^{-6.67}$, $v = 100$ km sec^{-1}. Also shown in Fig. 1 is the $S_y(f)$ that would be observed for daily observations of a pulsar having white intrinsic timing noise with spectral density 9×10^4 μs^2 Hz^{-1}. That is, the normalization is set by 1 μs (r.m.s.) white timing noise distributed over the Nyquist band[18] 0–0.5 cycles d^{-1} set by the daily sampling interval.

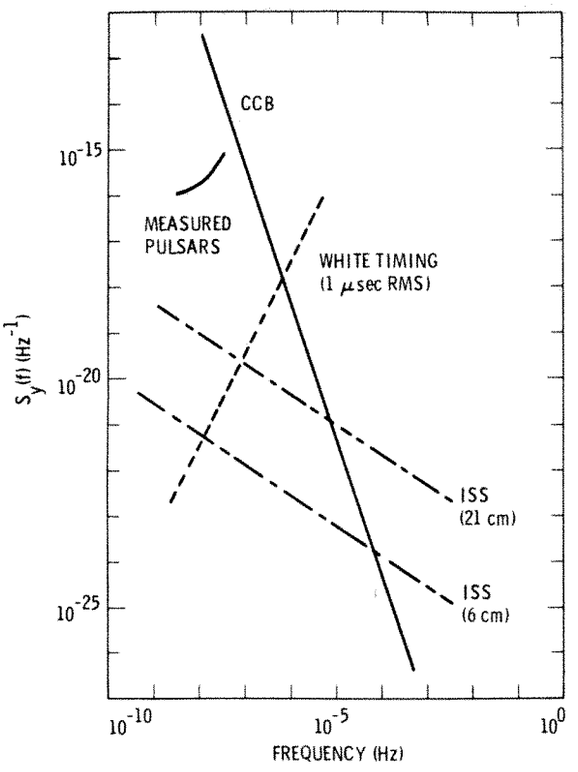

Fig. 1 Plot of power spectrum of fractional frequency fluctuations, $S_y(f)$, as a function of fluctuation frequency, f. Curve labelled 'CCB' is envelope of cosmic gravitational wave background spectra having closure density[19]; curve labelled 'Measured Pulsars' is observed limit to S_y from Hellings and Downs[2] and Romani and Taylor[3]; curves labelled 'ISS' are spectra expected due to interstellar scintillations (parameters: $\lambda = 0.21$ m and 0.06 m, $C_N^2 = 8\times10^{-5}\,\mathrm{m}^{-6.67}$, $z = 5$ kpc, $v = 100\,\mathrm{km\,s^{-1}}$); curve labelled 'White Timing' is for white intrinsic pulsar timing noise with r.m.s. value of 1 μs in the band 0–0.5 cycles d^{-1}.

From Fig. 1, the ISS limit is about three orders of magnitude below the current observational limit to S_y at $f = 10^{-8}$ Hz. However, as the intrinsic timing noise becomes lower ISS becomes increasingly important; white 1 μs r.m.s. timing noise becomes ISS-noise dominated at periods ~4 months for 21 cm observations. Expressed as a fractional frequency stability, the 21 cm ISS-curve in Fig. 1 corresponds to an Allan variance of $\cong 1.5\times10^{-14}\,(\tau/1\,\mathrm{yr})^{-1/6}$. (It should be noted that plasma phase scintillations are also an important noise source for gravitational wave observations in the 10^{-1} to 10^{-4} Hz frequency range[15]. Here fluctuations in the interplanetary plasma cause perturbations in the radio tracking record of a distant spacecraft[17]. The sensitivities achievable with an X-band tracking link are expected to be $\sim5\times10^{-15}$ at $\tau = 1{,}000$ s integration times for the raw data. Since the spacecraft coherently transponds the signal transmitted from the earth, a gravitational wave produces a characteristic three-pulse response[15] in the tracking time series. Thus correlation analysis should allow further improvement in the sensitivity in the spacecraft tracking case.)

What are the prospects for reducing the ISS noise? Since S_y is proportional to λ^4, observations at shorter wavelengths rapidly reduce ISS noise. However, pulsar signal-to-noise ratio considerations may make high frequency observations impractical. Dual frequency observations could be used to estimate and remove these dispersion measure fluctuations (ref. 20 for example). Although only changes in the dispersion measure are relevant here, the complicating factors of frequency-dependent pulse shape and frequency-dependent pulse broadening due to ISS diffraction will still make observations difficult at the level of precision required for a good ISS calibration. Without higher frequency observations or high-precision dispersion measure monitoring, the ISS-noise in Fig. 1 will constitute a limit to the sensitivity of ULF gravitational radiation observations even using timing data from an intrinsically noiseless pulsar.

I thank D. C. Backer, F. B. Estabrook, R. W. Hellings, and J. M. Rotenberry for discussions. This research was supported by the NASA Astronomy/Relativity branch and was carried out by the Jet Propulsion Laboratory, California Institute of Technology, under contract with NASA.

Surface albedo and the Sahel drought

M. F. Courel*, R. S. Kandel† & S. I. Rasool*‡

‡ Laboratoire de Météorologie Dynamique du CNRS, Ecole Normale Supérieure, F-75231 Paris Cedex 05, France

The persistence of the Sahel drought, which reached a peak in 1973, appears to be typical for such dry episodes over past decades and centuries[1–3]. Such strong persistence can be understood if a strong positive feedback mechanism is operating, partly driven by changes in surface properties[4,5]. The key factors in the mechanisms thus far studied are the surface albedo and the soil moisture, both of which affect the radiation balance at the surface, the first directly, the second indirectly through its influence on the latent heat flux. We have now studied the evolution of the albedo of this region since 1972. We find that dry season albedo in the Sahel (notably Ferlo and Gondo regions, see Fig. 1*b*) declined from a maximum close to 0.30 in 1973 to values close to 0.20 in 1979. This decline is consistent with changes in plant cover determined by analysis of spectral changes in the Landsat multispectral scanner (MSS) data and field studies[6,7].

The effect of drought, reducing soil moisture and thus evaporation and cloud cover, and increasing surface albedo as plant cover is destroyed, is generally to increase ground and near-surface air temperatures while reducing the surface radiation balance and exacerbating the deficit in the radiation balance of the local surface–atmosphere system. This entails increased atmospheric subsidence and consequently further reduced precipitation. The biogeophysical feedback mechanism involving albedo was first proposed by Charney[8], who noted that to the extent that man's agricultural and pastoral activities increased the stress on plant cover, they might be a factor in the increase of surface albedo, thus contributing to the persistence of the Sahel drought. Various numerical studies have confirmed that very large increases in surface albedo should indeed lead to substantial reduction in precipitation[9–12], but the question remains whether these assumed changes in surface albedo bear

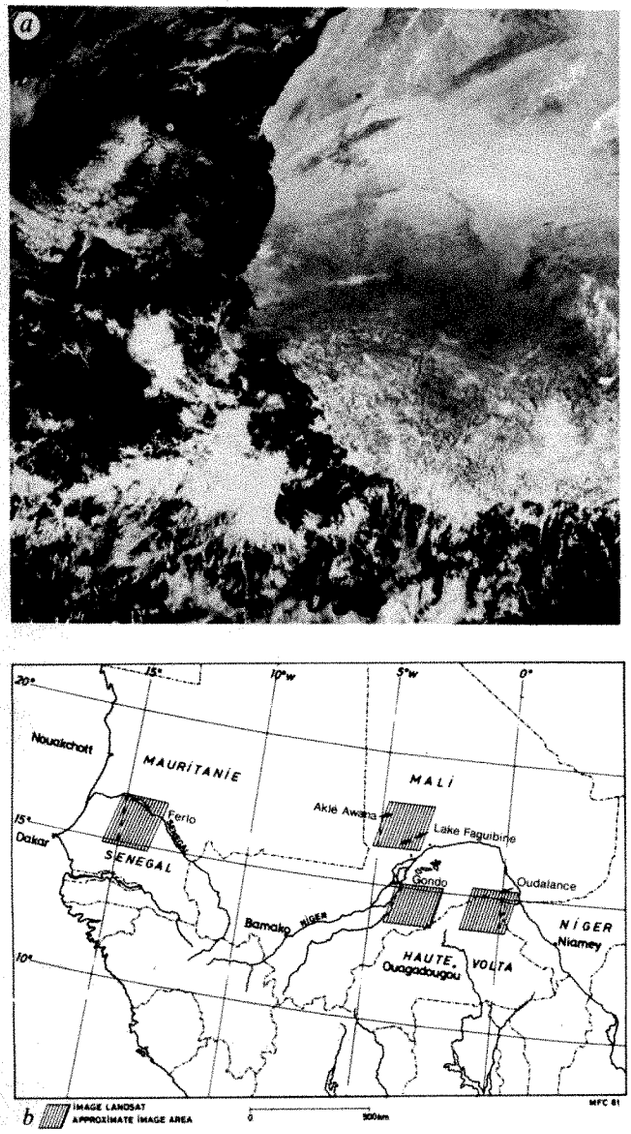

Fig. 1 West Africa: Saharo-Sahelian area. *a*, Portion of the Meteosat visible channel midday image of 2 August 1979. *b*, Map showing areas observed with Landsat; from west to east these are: Ferlo (Senegal), Aklé Awana with Lake Faguibine (Mali), Gondo (Mali), Oudalance (Haute-Volta).

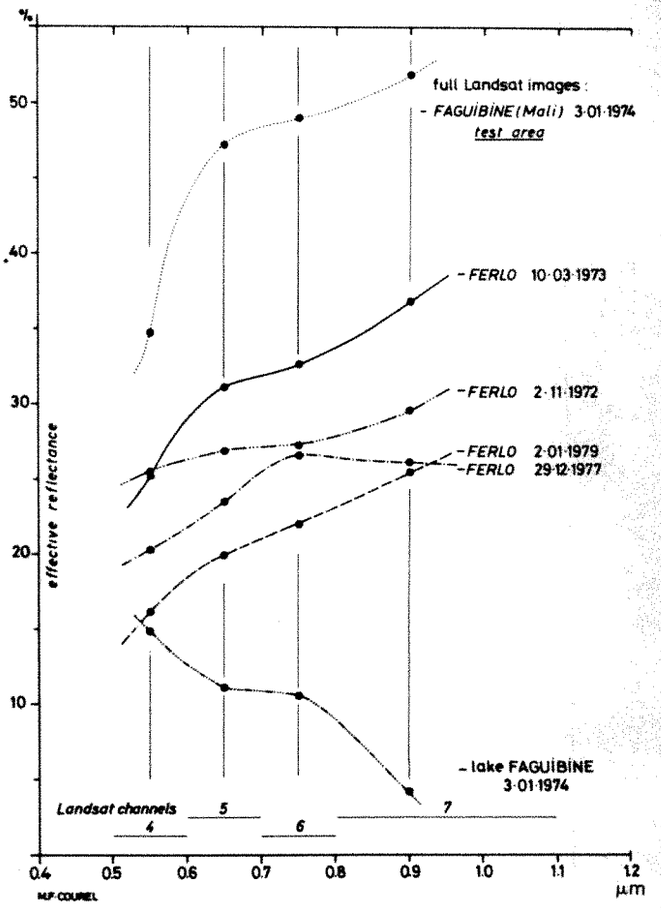

Fig. 2 Spectral reflectance based on Landsat MSS data. The two extreme curves are for the water surface of Lake Faguibine (lowest values) and for the full Landsat image including the lake and made up mostly of sand dunes (Aklé Awana), yielding the highest values.

any relation to those which have occurred in reality. For the period 1967–74 when the drought was intensifying, Norton and co-workers[13] found moderate increase in surface albedo, strong during the wet season months. The limitation that we found to the extension of the albedo, despite the continued relatively dry conditions, may result from accumulation of plant debris[14] (in regions such as Ferlo protected from overgrazing) and/or rapid recovery of grass cover even when the total amount of living vegetation continues to decrease. Thus the Charney albedo mechanism may not have a major role in the long-term evolution of the Sahel climate.

Our analysis considers the western part, from the Atlantic coast to longitude 3° E, of the Saharo-Sahelian zone of Africa, between latitudes 14 and 20° N. Norton and co-workers studied the changes in this region in the period 1967–74 using green sensor data from the Applications Technology Satellite (ATS-3), presenting results for areas 2° square[13]. We have studied the evolution of the region since 1972, using two sets of satellite data: (1) on the larger scale, directly comparable with the ATS-3 data, we use hourly visible channel data from Meteosat-1, for several periods of 1–6 days distributed through the year from November 1978 to November 1979. The spatial resolution of 2.5×5 km^2 (somewhat better than ATS-3) has been degraded to (40 km)^2 in preparing albedo maps of the entire region, and then to the 2° squares of Norton *et al.* (2) On a much finer scale, we use digital Landsat MSS data (spatial resolution 79 m) for several areas of (185 km)^2 (see Fig. 1*b*), obtained on a series of dates from 1972 to the present, at about 9.30 LT in each instance.

To estimate the planetary albedo from satellite measurements of emergent radiances, one must consider not only the sensor calibration, but also possible bias associated with limited spectral, angular and temporal sampling[15]. To estimate the surface albedo, one must also consider atmospheric effects.

The calibrated relatively-narrow bands of Landsat (Fig. 2) provide quasi-monochromatic radiance values[16,17] from which we compute the spectral reflectances and the isotropic estimate α_i of the albedo, integrated over the solar spectrum. Results obtained for the water surface of Lake Faguibine (Fig. 2) agree with theoretical computations of the spectral reflectance[18]. On the same Landsat images, the spectral albedo of the bright sand dune area of Aklé Awana is found to be quite high (from 0.35 in channel 4 to 0.52 in channel 7), in agreement with the values of 0.45–0.50 found for the solar spectrum-weighted albedo from the Meteosat images. This bright area was also used as a normalization point (with green channel albedo 0.41) in the earlier ATS-3 study.

For the Meteosat study, we have used Koepke's calibration[19] relating raw visible count to the radiance filtered by the Meteosat visible channel. These values are corrected using a 'filter factor' which is determined using spectral reflectance curves deduced from the Landsat MSS data and from laboratory studies of soil and plant samples from the area of interest[6,7]. This yields a good

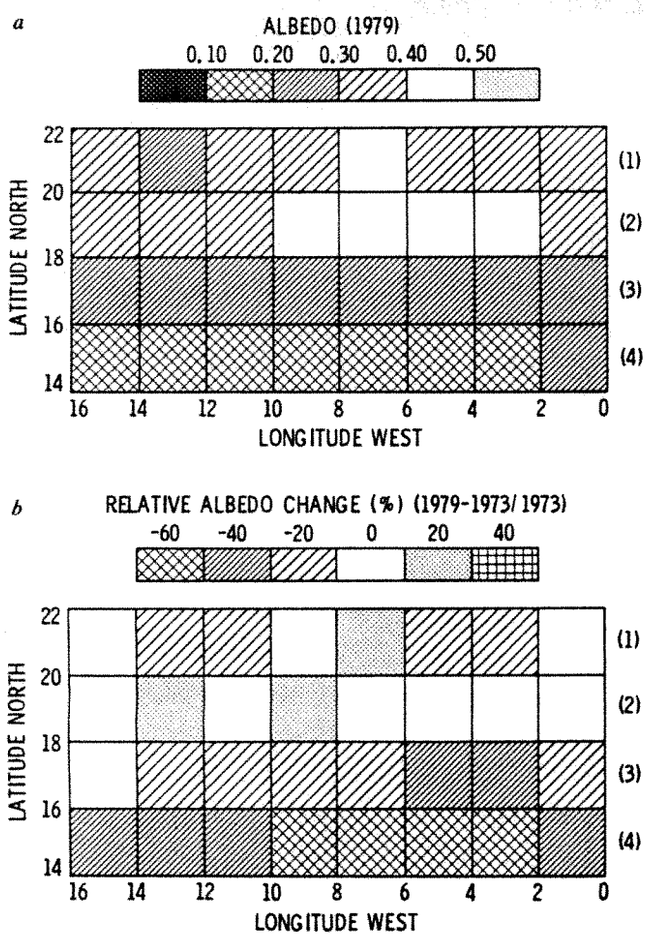

Fig. 3 *a*, Total solar spectrum-weighted surface albedo of the western Sahel, estimated from Meteosat-1 VIS data for 3–5 November 1979, with spatial resolution degraded to 2°. *b*, Relative albedo change $100\,\Delta\alpha/\alpha_{1973}$ observed between 19 October 1973 (ATS-3 data) and November 1979.

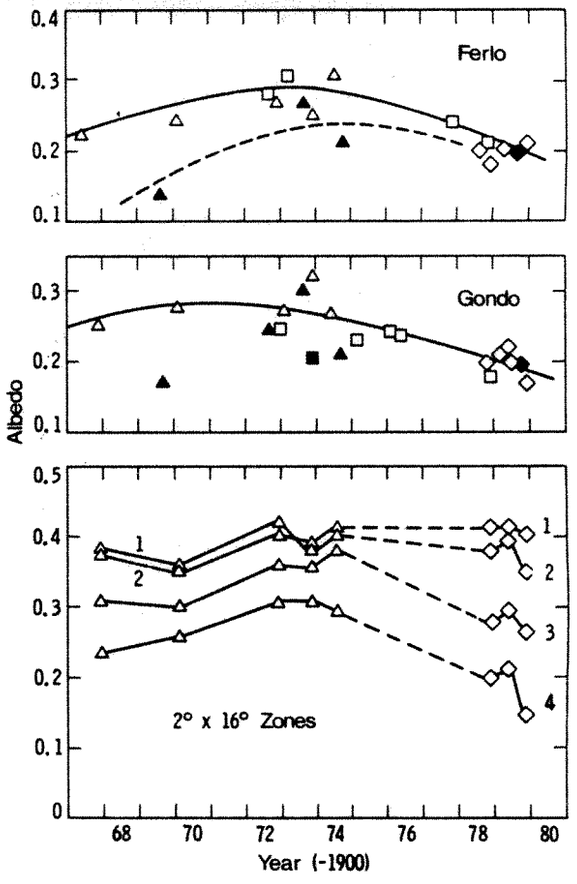

Fig. 4 Albedo history of the western Sahara and Sahel between 1967 and 1979: triangles, estimates based on the 2° maps of Norton *et al.*[13]; squares, Landsat data (Ferlo, Gondo); lozenges, Meteosat-1 data. The filled symbols correspond to observations in the rainy season. Curves 1–4 are integrated albedo values for the four strips 2° wide in latitude, extending from longitude 16° to 0° W, illustrated in Fig. 3.

estimate of the total solar spectrum-weighted reflectance. Also, corrections for anistropy are small (<0.02 in the instantaneous value of the albedo) because both Meteosat and Landsat are close to the zenith of the areas observed, so that the outgoing direction of greatest weight in determining the albedo is sampled. With the Meteosat data, temporal sampling (solar incidence sampling) is complete: we obtain several albedo estimates per day and find them approximately constant to solar zenith angle 60° over Sahelian and Saharan land surfaces. This suggests that the bias associated with the fixed 9.30 LT of the Landsat observation is fairly small, and even if such bias affects Landsat determinations of an annual albedo cycle, it disappears when comparing observations of different years made at about the same date.

Thus we believe that the various sampling biases in our data are small, or can be accounted for, as far as the planetary albedo values are concerned. The Landsat images used are cloud-free, and judging from reflectance of water surface, turbidity is low. The periods studied with Meteosat were chosen to be relatively cloud-free over the western Sahel, on the basis of visual inspection of both visible and IR images. Days with apparent high turbidity were rejected, and for each 2–3-day period studied, a minimum reflectance was used to estimate cloud-free albedo. Corrections for atmospheric effects (Rayleigh scattering, water vapour and ozone absorption, aerosol scattering and absorption) have been made following the procedure of Otterman and Fraser, and they are small (<5%) in the albedo range of interest[20–22]. Results are shown in Figs 3 and 4 and discussed further below.

Both the Landsat and the Meteosat data show that at its brightest spots (for example, Aklé Awana), the Sahara has an albedo close to 0.50. The mean albedo for the region from latitudes 18° to 23° N, and from longitude 10°W to the Greenwich meridian, is 0.42 ± 0.04, higher than the value of 0.35 used in Charney's model experiment[8,10], higher also than the values which often appear in surface albedo compilations[23]. The high value is consistent with the results of Otterman and Fraser[20–22], who studied a variety of desert sites using both Landsat MSS and laboratory data; it also agrees with some on-site measurements of bright sand in the Empty Quarter of Arabia[24]. It comes about essentially because of the near-IR rise in reflectance of the surface, observed in channels 6 and 7 of Landsat (Fig. 2).

In the western Sahel, the 1979 Meteosat data indicate effective surface albedos ranging from 0.15 to 0.25 (Fig. 3*a*). The values for the Ferlo and Gondo regions are in agreement with the Landsat data for the same period (Fig. 4). The earlier Landsat data for these same regions in 1972–73 also agree with values estimated from the ATS-3 2° × 2° albedo maps. Thus the Landsat data effectively bridge the gap between ATS-3 and Meteosat. For both the Ferlo and Gondo regions, dry season albedo declined from a maximum close to 0.30 in 1973 to values close to 0.20 in 1979 (Fig. 4), following the increase observed between 1967 and 1973. For the western Sahel as a whole, relative decreases of 20–60% were observed between 1973 and 1979 (Figs 3*b*, 4). This change is noteworthy in comparison with the relative stability (±15%) observed in the Saharan zone (Fig. 3*b* and curves 1 and 2 of Fig. 4) over the same period, indicating that the two sets of data are comparable.

Only a small fraction of existing satellite data has been examined, and uncertainties in establishing an albedo history are large. We cannot at present evaluate the 'normal' surface albedo of the Sahel, if indeed such a normal exists. However, even the smallest values obtained for the western Sahel (0.20 ± 0.05) and Sahara (0.42 ± 0.04) are larger than the 'climatological means' used in model calculations. Our study also shows that although drought conditions still persist in the Sahel, the surface albedo declined significantly between 1973 and 1979, in contradiction to the expectations of the Charney albedo feedback mechanism.

We thank E. H. Cissé for valuable assistance, Ph. Chamard and J. Otterman for stimulating comments and discussion, the Club du Sahel of the OECD for its support of this project, as well as the Centre National d'Etudes Spatiales and the ASP (DGRST/CNRS) Evolution des Climats, for partial support at the Service d'Aéronomie.

Predictability of north-east Brazil droughts

Stefan Hastenrath

Department of Meteorology, University of Wisconsin, 1225 West Dayton Street, Madison, Wisconsin 53706, USA

The droughts of north-east Brazil are unusually well defined in the departures of the quasi-permanent circulation systems in the tropical Atlantic sector. Anomaly patterns in the large-scale atmospheric and oceanic fields evolve in the course of the half-year preceding the March/April rainy season. Based on these diagnostic results, dynamically plausible predictor candidates are selected and entered into a stepwise multiple regression scheme. The circulation in the Atlantic sector proves to be essential for the prediction of rainfall anomalies, while predictor candidates from other parts of the globe are of subordinate importance. The regression equations derived from the 1921–56 record are used to produce rainfall forecasts for the years 1958–72. Forecast and observed values are strongly correlated. In particular, the severe 1958 drought was eminently predictable from this method.

The Sêcas or droughts of Brazil's 'Nordeste', which constitutes the eastern-most corner of the continet (Fig. 1), have recurrently led to starvation and mass exodus, and their eventual prediction has remained a central concern[1]. Earlier diagnostic studies[2–7] have elucidated the general circulation mechanisms of the Sêcas. Drawing on this diagnostic research and combining dynamical and statistical approaches, a method has been developed for the prediction of seasonal rainfall from the antecedent circulation departures. An early report of this work is made here, while full details will be presented elsewhere in due course[8].

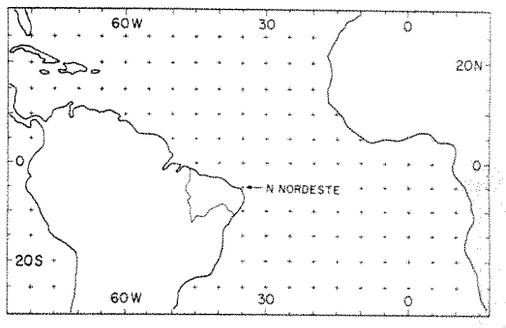

Fig. 1 Orientation map showing the northern Nordeste and 5° square areas for which ship observations were compiled.

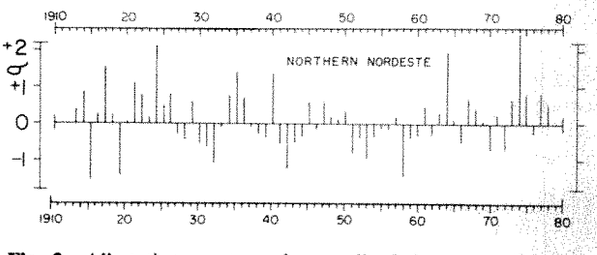

Fig. 2 All-station average of normalized departure of annual rainfall for the northern Nordeste.

The surface circulation in the tropical Atlantic is documented by ship observations stemming from the TDF-11 deck of the National Climatic Center at Asheville, North Carolina, compiled into 5° square values[4] (Fig. 1). The record of 1921–72 is used here, and elements of interest include sea level pressure (SLP), zonal (u) and meridional (v) components of resultant surface wind, sea surface temperature (SST), and total cloudiness. Rainfall observations for north-east Brazil are in part published[9]. Also used are selected observation series from other parts of the globe.

The march of the seasons in north-east Brazil is dominated by the latitudinal migration of the near-equatorial trough of low pressure and associated convergence zone over the western North Atlantic, sandwiched as they are between the subtropical highs of either hemisphere. During the Northern Hemisphere winter the trough and convergence zone shift southward, reaching a southernmost position in March and April. This is the peak of the rainy season in the drought-prone northern Nordeste, on which the present study is focused.

A collective of stations in the northern Nordeste (Fig. 1) are combined into rainfall index series of all-station normalized departure[3]. This precedure safeguards against the notorious space and time variability of tropical rainfall, so that the resulting index series are representative of the hydrometeorological conditions of large homogeneous areas. The October–September index ascribed to the calendar year containing the March–April rainy season peak, is plotted in Fig. 2. Such indices were also compiled for various portions of the hydrological year. Figure 2 illustrates the pronounced interannual variability of rainfall in the northern Nordeste, including the severe drought year 1958, remembered for its particularly serious social and economic consequences[1,3,7].

Analyses of large-scale circulation patterns[3] show that the Sêcas of the northern Nordeste are characterized by an equatorward expansion of the South Atlantic, and a poleward retraction of the North Atlantic high, associated with a northward displacement of the enclosed near-equatorial trough of low pressure. Concurrently, the zonally oriented bands of maximum cloudiness and precipitation stay farther north, the North Atlantic

Table 1 Percentage of explained variance, period 1921–40 plus 1946–56, for regression on March–April and March–September rainfall index

	O	N	D	J	F	N
Regression on						
March–April	18	55	25	63	56	71
March–September	34	61	48	66	71	—

trades weaken, and the South Atlantic trades become stronger than in the long-term mean. The SST pattern shows positive departures in a broad band across the North Atlantic and anomalously cold waters in most of the South and equatorial Atlantic. The following three factors apparent in the surface circulation seem conducive to drought: (1) the near-equatorial convergence band stays unusually far to the north of the northern Nordeste; (2) the anomalously cold south equatorial waters hamper the moisture content and instability of boundary layer flow upstream from the Nordeste; (3) the perennial contrast between warm north equatorial waters and cold waters to the south of the equator is enhanced. It has been hypothesized[7] that such a juxtaposition of SST anomalies would induce a meridional circulation cell with subsidence over the Nordeste.

During abundant rainy seasons in the northern Nordeste, departure patterns are approximately inverse to those typical of drought years. Anomaly configurations in the large-scale atmospheric and oceanic fields evolve gradually in the course of the preceding months[3].

The aforementioned diagnostic research suggests dynamically plausible predictors of north-east Brazil rainfall anomalies. Thus droughts may be heralded by: anomalously low/high pressure on the equatorward side of the North/South Atlantic subtropical high, enhanced easterly wind component over the low-latitude Atlantic, weakened northerly over the North Atlantic and enhanced southerly wind component over the equatorial and South Atlantic, positive SST departures in a zonally oriented band across the North Atlantic and anomalously cold surface waters in the equatorial South Atlantic, as well as an anomalously far northerly position of the near-equatorial belts of maximum surface convergence and cloudiness. Inasmuch as the pressure distribution over the Atlantic—which is instrumental in establishing the circulation patterns characteristic of the north-east Brazil rain-fall anomalies—appears related to large-scale mass redistributions of the Southern Oscillation type[3], various indications of the Southern Oscillation and parameters from more remote parts of the globe are of interest.

While the rainfall index series plotted in Fig. 2 extends from 1913–78, our ship data bank covers 1911–72. However, because of the scarcity of observations in the first decade of this period, only the record since 1921 is used here. With a view towards identifying suitable predictor candidates, isocorrelate maps were constructed of the October–September north-east Brazil rainfall index with SLP, SST, u and v wind components, and cloudiness over the Atlantic. The highest correlations plausibly occur in the areas described above as being meteorologically significant for the various atmospheric and oceanic fields. The regions of correlation exceeding 0.3 in absolute value were identified and for the combination of adjacent 5° blocks with correlation of same sign and exceeding 0.3, time series were compiled to serve as input to a regression model. This screening is intended to safeguard against noise. Other predictor candidates considered include pre-season rainfall in the northern Nordeste itself, rainfall at Georgetown and Paramaribo in the Guyanas, pressure at Port Stanley in the South Atlantic, temperature in the southeastern United States, India rainfall[10], and Wright's[11,12] Southern Oscillation index.

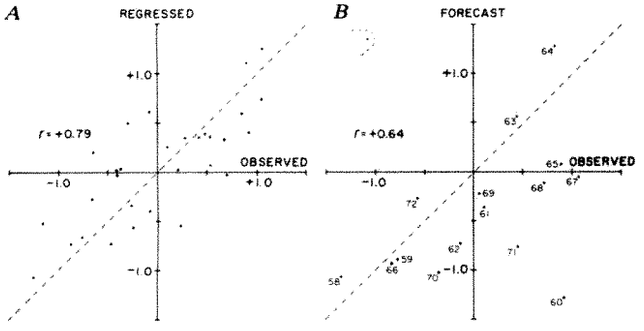

Fig. 3 Scatter diagrams of March/April rainfall index based on observations that would exist by the end of January. *A*, Regression, period 1921–40 plus 1946–56, correlation coefficient $r = +0.79$. *B*, Forecast, period 1958–72, with numbers indicating the years, $r = +0.64^{**}$. (Two asterisks denote significance of correlation coefficient at the 1% level.) Broken lines denote 45° angle. Quenouille's[17] method is used to account for the reduction of effective number of degrees of freedom due to persistence.

Of 17 candidate series, 11 possess a correlation with north-east Brazil rainfall exceeding 0.3 in absolute value, and were input to a stepwise multiple regression scheme with a 5% significance margin[13,14]. This identified as most important predictors SLP, SST, and u and v wind components over the tropical Atlantic. Of further use was the pre-season rainfall in northern north-east Brazil itself, and the May–June–July Southern Oscillation index value[11,12].

Regression models were constructed from the record 1921–40 plus 1946–56, for all months from October through March for two 'predictands', namely the March–April and the March–September rainfall indices. Part *A* of Fig. 3 is a scatter diagram for January of 'regressed' versus 'observed' values of the March–April rainfall index; the other models are not depicted here. Table 1 lists the variance explained by the regression models for the various months. The variance explained generally increases as one approaches the peak rainy season, no hypothesis being offered for the remarkably weaker relation in December. The peak March–April and March–September rainfalls are specified to a very high degree by the departure ensemble of the general circulation in February and March. However, February leaves no lead time for the practical use of the forecast, while November accounts for a smaller percentage of the rainfall variability. Accordingly, the January models merit particular attention.

The regression models developed from the 1921–40 plus 1946–56 record were used to predict the rainfall anomalies of the 15 years 1958–1972. Part *B* of Fig. 3 is a scatter diagram of the January model predicting the March–April rainfall index. No details are presented here for the other January model (March–September rainfall) and the two November models. Information such as part *A* of Fig. 3 serves as a background reference for rainfall index forecasts for years beyond the base period of the regression models, as presented in part *B* of Fig. 3.

As a basis for the appraisal of forecast performance, various forms of evidence are considered. (1) The scatter diagram in part *B* of Fig. 3 shows a positive relation between forecast and observed values, although the scatter is larger than for the regression model plotted in part *A*. (2) Correlation coefficients between forecast and observed values such as given in part *B* of Fig. 3 are high. (3) In addition, skill scores[15] and stochastic joint probabilities[16] were calculated. These also indicate appreciable forecast skill. Details are not discussed here, but the pertinent information is contained in Fig. 3. In context, the various measures of prediction quality all bear out a remarkable forecast performance. The forecasts are particularly good for the extreme drought year 1958.

A wide range of dynamically plausible predictor candidates was examined, but it is found that the large-scale atmospheric and oceanic fields in the tropical Atlantic are most essential for the prediction of extreme hydrometeorological regions in the northern Nordeste. For operational applications, such parameters are required on a timely basis. Remote sensing by satellite appears an obvious choice, of particular promise being lower-tropospheric cloud motion vectors, SST, and cloudiness or its proxies. It must be realized, however, that time series of inter-

nally consistent parameters extending over at least ten years are needed, absolute calibration not being essential. Such a satellite-derived reference climatology has not yet been created. The development of an operational monitoring and prediction system entails a substantial material commitment. This is something that deserves to be considered seriously in the light of the demonstrated predictability of northeast Brazil droughts and their social and economic impact.

This research was supported by NSF Grant ATM82-00511. M. C. Wu and P. S. Chu participated in the regression study.

Evidence against surface state limitations on efficiency of p-Si/CH_3CN junctions

Charles M. Lieber, Chris M. Gronet & Nathan S. Lewis*

Department of Chemistry, Stanford University, Stanford, California 94305, USA

We report here the first efficient p-type Si-based semiconductor–liquid junction system. p-Type Si photocathodes have been previously reported to yield open circuit photovoltages, V_{oc}, of 0.38–0.40 V with several redox systems[1–8]. Photocurrent–voltage studies of p-Si cathodes in CH_3CN solvent have demonstrated 2.5% efficiency for conversion of 632.8-nm light to electricity with the *N,N'*-dimethyl-4,4'-bipyridinium$^{2+/+}$ redox system[1], and 0.5–2.4% with other macrocyclic complexes[7,8]. Such modest energy conversion efficiencies for small band gap semiconductors have been attributed to surface states which pin the semiconductor Fermi level[6–9] and promote recombination processes[10]. However, we find that p-type Si/CH_3CN interfaces can yield solar conversion efficiencies in excess of 10%, and can display open circuit photovoltages within 0.08 V of the theoretical limit for an ideal junction.

We have chosen the cobaltocene$^{+/0}$ ($CoCp_2^{+/0}$)/1.0 M $[(C_2H_5)_4N]^+[BF_4]^-/CH_3CN$ redox system to probe the interface behaviour of p-Si in CH_3CN solvent. $(CoCp_2)^+(PF_6)^-$ is sufficiently soluble in CH_3CN to be used in concentrations which minimize mass transport polarization losses at the working electrode. In addition, the electrochemically reversible[11,12] $CoCp_2^{+/0}$ system possesses an $E^{0\prime}$ (−0.95 V/SCE) sufficiently negative to effect a large degree of band bending at the semiconductor–liquid interface. Uncompensated ohmic resistance losses can be minimized with proper cell design in this highly conductive ($\rho = 18\ \Omega$-cm) electrolyte; thus, all current–voltage parameters have been measured under potentiostatic control versus a Pt reference electrode in a 0.2-mm outer diameter Luggin capillary. Only when all of the above criteria are met might one conclude that any inefficiencies are due to surface states at the interface.

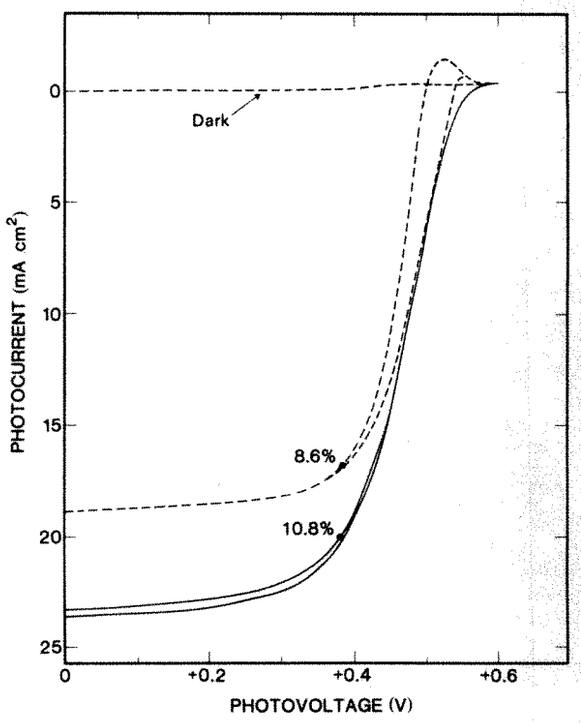

Fig. 1 Current–voltage properties of a single crystal p-type Si photocathode in a stirred CH_3CN/1.0 M $[(C_2H_5)_4N]^+[BF_4]^-$/0.2 M cobaltocenium/0.5 mM cobaltocene solution. Light intensity is 70 mW cm^{-2} from an ELH-type tungsten–halogen solar simulator, and photocurrent–voltage curves are uncorrected for any losses due to optical reflection or solution absorption. ---, Shiny Si surface obtained from a 10-s etch in 48% aqueous HF, followed by a 10-s rinse with H_2O, then a 10-s rinse with CH_3CN. —, Matte-textured surface[13] in identical illumination conditions. Both current–voltage curves were measured potentiostatically (50 mV s^{-1}) versus a Pt reference electrode (−0.82 V/SCE) through a Luggin capillary, and represent photoelectrode efficiencies of the semiconductor cathode.

Use of a mirror-finished p-type Si electrode (HF-etched, 1.5 Ω-cm resistivity, (100) oriented) in the optimized 1.0 M $[(C_2H_5)_4N]^+[BF_4]^-$/0.2 M $CoCp_2^+$/0.5 mM $CoCp_2/CH_3CN$ system with 70 mW cm^{-2} of ELH-type tungsten–halogen irradiation[13–15] yields V_{oc} of 0.48–0.52 V, short circuit photocurrent densities, J_{sc}, of 20–21 mA cm^{-2}, fill factors of 0.52–0.55, and photoelectrode efficiencies for conversion of incident light to electricity of 8.5 ± 0.8% (Fig. 1). Texturing of the photoelectrode surface to expose (111) planes and produce a matte black surface yields decreased reflectivity[13] and produces a system with $V_{oc} = 0.49$–0.53 V, $J_{sc} = 23$–26 mA cm^{-2}, and efficiencies of 10.5 ± 1.0%. Actual direct sunlight yields similar behaviour, and at 70 mW cm^{-2} of insolation on matte-etched surfaces, we observe $V_{oc} = 0.49$–0.53 V, $J_{sc} = 23$–26 mA cm^{-2}, and efficiencies of 10.5 ± 1.0%.

The photocurrents depicted in Fig. 1 are certainly not due to cathode corrosion. With suitable precautions to exclude air and water from the cell, we have maintained stable (±10%) short circuit currents at AM2 photocurrent densities (>20 mA cm^{-2}) for passage of $>2 \times 10^3$ C cm^{-2} through the interface. Longer term stability of this system has not been investigated because of the documented photodecomposition processes of $CoCp_2$ (ref. 11); however, other soluble, outer-sphere redox couples should be available which would yield similar photocurrent–

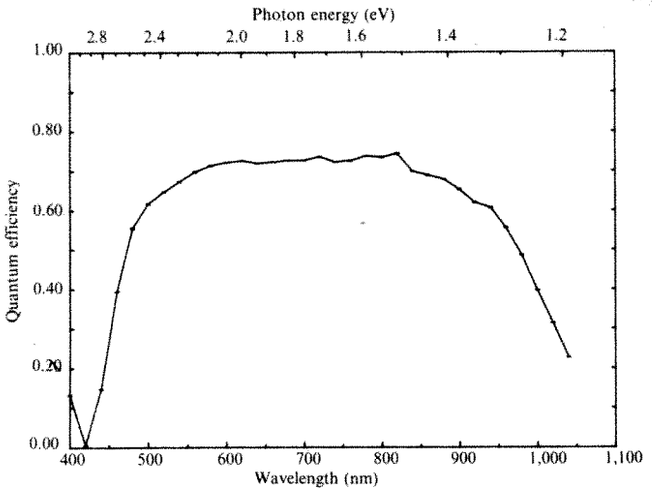

Fig. 2 Spectral response of the short circuit quantum yield plotted against wavelength of incident photons for the p-Si/CH_3CN/cobaltocene$^{+/0}$ system. Average incident light intensity is 1 mW cm^{-2}, and quantum efficiencies (±10%) are uncorrected for losses due to optical reflection or solution absorption of light. Shiny p-Si cathodes yield 20–30% less current than a matte-textured surface, but both electrodes exhibit excellent response over a broad spectral range.

voltage parameters. Our stability and efficiency measurements represent photoelectrode efficiencies of the working electrode only, and do not represent actual operating two-electrode solar cells. However, the system certainly illustrates that it is possible to observe excellent junction behaviour for p-Si photocathodes in the proper conditions.

The photocurrent response versus incident photon energy for mirror-finished p-Si cathodes is depicted in Fig. 2. The onset of photocurrent is in accord with the 1.1-eV absorption edge of Si, and the high-energy cutoff is attributable to solution absorption of light. An integration of the spectral response properties in Fig. 2 with the solar spectral input yields short circuit photocurrent densities which are in excellent agreement with experimental J_{sc} values. The observation of significant photocurrent near the Si absorption edge implies that unthermalized hot carriers do not provide the sole source of photocurrent flow at these p-Si/CH_3CN junctions. In addition, the high absolute value of the short circuit quantum efficiency, both at low light intensities and solar irradiance levels, yields little evidence for surface recombination sites at the p-Si/CH_3CN interface.

We view these results as consistent with observations in our laboratory[13,17] and by others[18,19] that the chemistry of the Si/SiO_2 interface will preclude substantial carrier recombination by surface states. With a minority carrier diffusion length of 300 μm and a dopant density of 2×10^{15} carriers cm^{-3}, photocurrent densities of 20 mA cm^{-2} imply a bulk diffusion-limited open circuit voltage of 0.59 V (refs 20–22). Thus, the V_{oc} of 0.48–0.52 V at 20–21 mA cm^{-2} for the p-Si/CH_3CN system is within 0.08 V of the maximum attainable value for any junction fabricated with our semiconductor samples. Furthermore, the V_{oc} of p-Si/CH_3CN junctions substantially exceed V_{oc} values typically found for direct p-Si/Au or p-Si/Pt Schottky barriers ($V_{oc}<0.20$–0.25 V)[23]. In fact, the V_{oc} values at high light intensity (>1 W cm^{-2}) for the p-Si/CH_3CN system (>0.55 V) exceed reported values of barrier heights for p-Si Schottky barriers with metals such as Ag, Au, Cr, Cu, Mo, Ni, Pb, Pd, Pt and W (ref. 20). Clearly, intrinsic surface states do not dominate the chemistry at both the semiconductor/liquid and semiconductor/metal interfaces.

Our data on the p-Si/CH_3CN interface yield no evidence for surface state limitations which would prevent the rational design and study of efficient semiconductor–liquid junctions. Investigations of the p-Si system are thus consistent with recent studies of other common, small band gap semiconductors (n-Si (ref. 13), n-GaAs (ref. 24), n-$GaAs_{1-x}P_x$ (ref. 25)) which suggest that control of bulk electrode properties and of solution overpotential losses can eliminate most inefficiencies previously ascribed to surface states at the semiconductor–liquid interface. Extension of the $CoCp_2^{+/0}$ redox system, and similar metallocenes, to other photocathode materials is underway.

We thank G. Cogan and J. Gibbons for helpful discussions, and for access to spectral response and metal evaporation facilities at SERA Solar Corporation. We acknowledge a Cottrell Grant from the Research Corporation for partial support of this work.

Photochemical dehydrogenation of ethanol in dilute aqueous solution

John Handman, Anthony Harriman & George Porter

Davy Faraday Research Laboratory, The Royal Institution, 21 Albemarle Street, London W1X 4BS, UK

The need for alternative sources of energy has stimulated research into the storage of sunlight as chemical potential. Many systems have been investigated but photogeneration of H_2 seems to be the most practical. The cyclic photodissociation of water has yet to be realized in homogeneous solution using visible light, although heterogeneous photosystems are known[1–3]. Efficient photogeneration of H_2 in homogeneous conditions can be achieved[4–7] at the expense of an added electron donor but such systems have little application in practical devices. Replacement of the sacrificial donor with waste material, for example sulphide[8], offers a route for improving these systems and, here we describe efficient H_2 photogeneration from a system using aqueous ethanol, as available from low grade fermentation, as donor. To couple the photoproduction of H_2 to the oxidation of ethanol we have used NADH/alcohol dehydrogenase as a relay.

Dichloro tin(IV) *meso*-tetrakis (*N*-methyl-4-pyridyl)porphine ($SnTMPyP^{4+}$) dissolves readily in water throughout the entire *p*H range and such solutions absorb strongly all light

0028–0836/84/060534—02$01.00

© 1984 Macmillan

below 620 nm and are therefore capable of collecting some 40% of the energy available in sunlight. Upon excitation with visible light ($\lambda < 620$ nm), the triplet excited state of the metalloporphyrin is formed in high yield ($\phi_T \sim 0.95$) and it is quite long-lived ($\tau_T = 0.9$ ms) in the absence of oxygen. The triplet state is a powerful oxidizing agent and is quenched by NADH at the diffusion controlled bimolecular rate limit due to transfer of a single electron, as shown by flash photolysis studies.

$$^*SnTMPyP^{4+} + NADH \rightarrow SnTMPyP^{3+\cdot} + NADH^{+} \quad (1)$$

$$NADH^{+} \rightleftharpoons NAD^{\cdot} + H^{+} \quad (2)$$

$$pK = -4$$

The one-electron reduction product of the metalloporphyrin is the π-radical anion ($SnTMPyP^{3+\cdot}$) which can be identified by its characteristic absorption spectrum[9]. The π-radical anion is unstable with respect to disproportionation at $pH < 12$, although it persists for many minutes in alkaline solution, and it is also reduced rapidly by the oxidized form of the donor.

$$2\,SnTMPyP^{3+\cdot} + H^{+} \rightleftharpoons SnTMPyP^{4+} + SnTMPyPH^{3+} \quad (3)$$

$$SnTMPyP^{3+\cdot} + NAD^{\cdot} + H^{+} \rightarrow SnTMPyPH^{3+} + NAD^{+} \quad (4)$$

Both processes result in formation of the metallophlorin ($SnTMPyPH^{3+}$), which is a protonated π-dianion and has a characteristic absorption maximum centred at 830 nm (refs 10, 11). The phlorin is stable in outgassed aqueous solution over the pH range 4–14, although it undergoes acid/base equilibration and is quantitatively reoxidized to the original metalloporphyrin on aeration. For light of λ550 nm, the quantum yield for formation of the phlorin was 0.60 ± 0.05 for concentrations of NADH of 2×10^{-3} mol dm^{-3} and $SnTMPyP^{4+}$ of 1×10^{-5} mol dm^{-3} at pH 7.5. Since the oxidized form of the donor can also reduce ground state metalloporphyrin

$$SnTMPyP^{4+} + NAD^{\cdot} \rightarrow SnTMPyP^{3+\cdot} + NAD^{+} \quad (5)$$

the overall process requires one photon to drive a two-electron reduction of the porphyrin

$$SnTMPyP^{4+} + NADH \xrightarrow{h\nu} SnTMPyPH^{3+} + NAD^{+} \quad (6)$$

It should be emphasized that the porphyrin/phlorin cycle is exceptionally clean for $SnTMPyP^{4+}$ at $pH > 4$ and, unlike most metalloporphyrins studied to date[9,10], irreversible formation of the chlorin is unimportant.

When colloidal Pt (ref. 12) is present, irradiation ($\lambda < 620$ nm) of the solution results in formation of H_2 and the phlorin is no longer observed as a reaction product. Depending on pH, the phlorin, the π-radical anion and NAD$^{\cdot}$ are all capable of reducing protons to H_2 on the surface of a Pt catalyst. With a Pt concentration of 10^{-4} mol dm^{-3} and irradiation with λ550 ± 10 nm, the quantum yield for formation of H_2 was found to be 0.43 ± 0.05 at pH 7.5. Thus, conversion of the reducing equivalents into H_2 is almost quantitative and H_2 formation is not restricted to neutral solution but occurs throughout the range $5 < pH < 10$. It was found that Pt catalysed formation of the metallochlorin, albeit ineffectively, so that at high concentrations of Pt the cycle with respect to the porphyrin was no longer entirely clean. Although very efficient, the above cycle is sacrificial in that the evolved H_2 is at the expense of oxidation of NADH to NAD^{+} and there is a concomitant increase in pH.

$$H_2O + NADH \overset{h\nu}{\rightleftharpoons} NAD^{+} + H_2 + OH^{-} \quad (7)$$

In our conditions, there is no experimental evidence that Pt catalyses reduction of NAD^{+} by H_2 although this reaction is expected to occur on standing in the dark.

Regeneration of NADH from NAD^{+} can be achieved readily using ethanol and an enzyme catalyst such as yeast alcohol dehydrogenase (YADH).

$$C_2H_5OH + NAD^{+} \xrightarrow{YADH} CH_3CHO + NADH + H^{+} \quad (8)$$

Thus, irradiation of $SnTMPyP^{4+}$ (10^{-5} mol dm^{-3}) with green light in N_2-purged aqueous solution at pH 7.5 containing NADH (2×10^{-3} mol dm^{-3}), colloidal Pt (10^{-4} mol dm^{-3}), YADH (25 mg dm^{-3}) and ethanol (2% v/v) resulted in sustained generation of H_2. In a typical experiment, the rate of H_2 formation was approximately 440 cm^3 per dm^3 of solution per h at an incident light intensity of about 10^{20} photons min^{-1}. On prolonged irradiation, turnover numbers of 86 and 131,000 respectively have been observed for NADH and YADH, although that for NADH is not exhaustive. Only a small fraction of the metalloporphyrin is lost (via chlorin formation) in these conditions whilst the ethanol can be converted quantitatively into acetaldehyde and H_2 and the quantum yield for formation of H_2 remained at 0.43 ± 0.05. The solution pH remains constant during the overall reaction and neither acetaldehyde nor its solvate inhibit H_2 evolution. The rate of H_2 formation shows no significant decrease until the YADH or ethanol has been consumed. The rate and quantum yield of H_2 formation compare favourably with any previously reported sacrificial H_2 evolving photosystem while the longevity of the present system greatly exceeds that of any previous system.

Overall, the photoreaction may be summarized by the following scheme:

$$\begin{matrix} H^{+} \\ Pt \\ H_2 \end{matrix} \Big) \Big(\begin{matrix} SnTMPyPH^{3+} \\ \\ SnTMPyP^{4+} \end{matrix} \Big) \overset{h\nu}{\Big)} \Big(\begin{matrix} NAD^{+} \\ \\ NADH \end{matrix} \Big) \Big(\begin{matrix} C_2H_5OH \\ YADH \\ CH_3CHO + H^{+} \end{matrix} \quad (9)$$

Dehydrogenation of ethanol

$$C_2H_5OH_{(L)} \rightarrow CH_3CHO_{(L)} + H_{2(G)} \quad (10)$$

$$\Delta G^0 = 42\ kJ\ mol^{-1}$$

is thermodynamically uphill so that energy is stored during the reaction. The overall efficiency for storage of light energy (λ = 620 nm) is $(0.43 \times 42/193)$ 9.4%. The photoreaction might offer a useful alternative to distillation of ethanol from low grade fermentation processes. However, the idea of using an enzyme to regenerate the electron donor is not restricted to ethanol but D-glucose or lactate could be used instead. Finally, we note that the phlorin is extremely stable in the absence of air so that the photoreaction could be used in a flow cell enabling the H_2 to be liberated at a specific site.

We thank the SERC, the EEC and General Electric (Schenactady) for financial support. Further details regarding the reaction mechanism and intermediates will be reported elsewhere.

Large mantle heterogeneity beneath French Polynesia

Ph. Vidal*, C. Chauvel† & R. Brousse‡

New strontium, lead and neodymium isotope compositions of volcanics from two volcanic island chains of French Polynesia (Marquesas, Australes) are presented. The data from Marquesas fall in the well-established oceanic islands field and are very similar to those of the Society Islands of French Polynesia. In contrast, Tubuaii Island basalts from the Australes chain exhibit very low $^{87}Sr/^{86}Sr$ ratios (~0.7028) and the highest $^{206}Pb/^{204}Pb$ (~21.1) and $^{208}Pb/^{204}Pb$ (~40.4) ratios ever reported for an oceanic island. Their ε_{Nd} value is ~+4.9. These data are similar to those of St Helena, although even more extreme. This convergence indicates that a comparable and as yet undefined process took place in the mantle beneath the Atlantic and Pacific oceans. The isotopic data for the Polynesian volcanics encompass almost the entire range of Sr and Nd isotopic ratios found in oceanic islands ($^{87}Sr/^{86}Sr = 0.7028–0.7083$; $^{143}Nd/^{144}Nd = 0.51257–0.51297$) and more than half of the Pb isotope range ($^{206}Pb/^{204}Pb = 18.9–21.1$; $^{208}Pb/^{204}Pb = 38.9–40.4$).

Mid-ocean ridge basalt (MORB) and oceanic island volcanism are known to originate from totally distinct mantle sources and to have been separated for at least 1,000 Myr. Despite the number of models[1–9], mostly based on isotopic data, the following points are still matters of discussion: (1) What is the depth of the ocean island basalts source regions? Are they located in the upper or in the lower mantle? (2) Are the large variations in isotopic ratios observed in volcanic rocks at the present time the result of primary heterogeneity of the U/Pb, Rb/Sr and Sm/Nd ratios at the time of the formation of the mantle or of later processes? (3) In the case of the lower mantle hypothesis, what is the extent of the interaction with the core? (4) Does altered and subducted oceanic crust or continental material contribute to the oceanic island isotopic pattern? (5) To what degree have oceanic island magmas been chemically and isotopically contaminated as they rise through the depleted upper mantle?

Although a number of oceanic islands are now well documented regarding isotopes there are only a few high-precision data on Pb, Sr and Nd isotopes on the same samples. In addition, a strong emphasis has been put on Atlantic islands and few data are available on the Indian and Pacific oceans. A more precise answer to these questions will be given when the whole picture of isotopic pattern (Pb, Sr, Nd, Hf, rare gases) on all oceans becomes available.

We report here some new measurements on French Polynesia which due to its large surface area (2,200,000 km^2; 8–18 lat. south and 135–155 long. west) allows us to study the mantle heterogeneity on a larger scale than was possible with the other oceanic islands.

In the central Pacific Ocean, four volcanic chains are aligned parallel to the Hawaiian chain: the Marquesas Islands, the Gambier–Tuamoutou Islands, the Society Islands and the Australes Islands (formally called Tubuaii Islands) (Fig. 1). Each of these chains can be interpreted as being the result of a hot spot[10] which is located at the south-east end of each chain.

In the Marquesas Islands, volcanic activity ranges in age from 6.3 ± 0.2 Myr (in Eiao Island) to 1.30 ± 0.02 Myr (in Fatu Hiva Island)[11,12]. In the Australes Islands, volcanism extends from 18 Myr (at the north-west end of the chain[13–15]) to the present as indicated by active volcanism on MacDonald seamount at the south-east end of the chain[16,17].

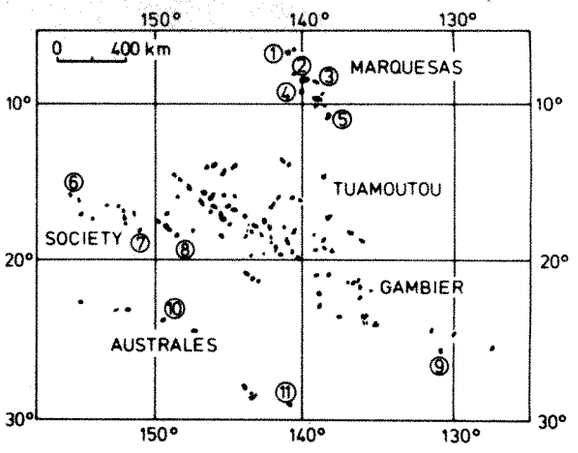

Fig. 1 Location of the Polynesian islands in the Central Pacific. Numbers refer to the islands: 1, Eiao; 2, Nuku Hiva; 3, Ua Huka; 4, Ua Pou; 5, Fatu Hiva; 6, Maupiti; 7, Tahiti; 8, Mehetia; 9, Pitcairn; 10, Tubuaii; 11, MacDonald. Ranges in lava compositions are as follows: Ua Pou—a potassic series, picrite to K-phonolite[21]; Ua Huka—undifferentiated basalt[20]; Nuka Hiva—alkali-olivine basalt to alkali-rich quartz-trachyte[22]; Tubuaii—five distinct series are observed[23]: (i) basal series of the main volcano (12–10.5 Myr) composed of undifferentiated transitional basalts (5436); (ii) medium series of the main volcano (9.5–6.8 Myr) composed of undifferentiated alkali basalts (5434); (iii) top series of the main volcano ranging in composition from differentiated basanites (5433) to phonolites; (iv) a group of later intrusions (≅5.7 Myr) composed of analcimites (5435); (v) the succession of the secondary volcano located on the west part of the island (10.5–8 Myr) ranging in composition from murites (5437) to phonolites. As noted above, one sample has been selected in each series, each of these samples representing the more primitive liquid of the series.

In both the Marquesas and Australes Islands, the volcanic products are of alkalic affinity. Each island is formed by the succession of at least two different volcanic sequences[18], the alkalic character increasing from the beginning to the end of the sequence[19].

We analysed samples collected in three different islands of the Marquesas chain: Ua Pou, Ua Huka and Nuku Hiva, as well as samples from Tubuaii Island in the Australes chain, and the results are presented in Table 1 and in the legend to Fig. 1.

Lead chemistry and mass spectrometry have been performed in Rennes using the method described by Vidal and Clauer[24]. Part of the Sr data was obtained in Rennes using the technique described by Chauvel[25]. The other part of the Sr data as well as the Nd data were obtained in Mainz using the analytical procedures reported by White and Patchett[26].

Sr, Pb and Nd isotopic ratios are reported in Table 1. Due to their low ages (2–10 Myr) and their low Rb/Sr ratios, the *in situ* correction for the increase of $^{87}Sr/^{86}Sr$ by radioactive decay is for most of the samples within the analytical uncertainties. However, for a few samples the correction is on the fourth decimal place. The measured Nd isotopic ratios can be considered as initial ratios because the rocks are very young. For Pb isotopes no correction has been made due to the lack of data regarding Th and U contents. Only $^{206}Pb/^{204}Pb$ ratios are actually sensitive to this correction, although they are also generally considered as initial ratios. In fact, in the present study, the very close grouping of $^{206}Pb/^{204}Pb$ ratios within one single island whatever the petrographic type enables us to consider the observed ratios as closely approaching the initial values.

The results are plotted on four diagrams: $^{207}Pb/^{204}Pb$ against $^{206}Pb/^{204}Pb$ and $^{208}Pb/^{204}Pb$ against $^{206}Pb/^{204}Pb$ (Fig. 2*a*, *b*), $^{143}Nd/^{144}Nd$ against $^{87}Sr/^{86}Sr$ (*c*) and $^{87}Sr/^{86}Sr$ against $^{206}Pb/^{204}Pb$ (*d*).

In all diagrams, the data from Marquesas plot in the middle of the field defined by the other oceanic islands. They are particularly comparable to the data of Society Islands (refs 27,

$^{87}Sr/^{86}Sr$ ratios are normalized to $^{86}Sr/^{88}Sr = 0.1194$ and $^{143}Nd/^{144}Nd$ ratios to $^{144}Nd/^{146}Nd = 0.7219$. Values for E & A standard and La Jolla standard measured at the Max-Planck-Institute are $^{87}Sr/^{86}Sr = 0.707998 \pm 40$ (2σ pop) and $^{143}Nd/^{144}Nd = 0.511847 \pm 21$ (2σ pop) respectively. Value in Rennes for NBS 987 standard is $^{87}Sr/^{86}Sr = 0.71020 \pm 4$ (2σ). Concentrations in Rb, Sr and Pb have been measured by the XRF method. Precision is 2% for Rb and Sr contents and 10% for Pb content.
* As estimated from replicates of NBS 981 analysis, maximum errors on $^{206}Pb/^{204}Pb$, $^{207}Pb/^{204}Pb$ and $^{208}Pb/^{204}Pb$ ratios are 0.15% and on $^{207}Pb/^{206}Pb$, 0.07%.
† Sr data obtained in Max-Planck-Institute, Mainz.

28 and W. M. White, unpublished data). This suggests that the Marquesas and the Society Islands may originate from similar sources. In contrast, Tubuaii Island field is very different from the other oceanic islands, with the exception of St Helena.

The strontium data for the Marquesas Islands, presented here, are in excellent agreement with those of Duncan and Compston[29]. Within one single island the spread in $^{87}Sr/^{86}Sr$ ratios can be very large. In contrast, the lead isotopic ratios are very homogeneous for each island. The spread in strontium isotopic ratios might be related to some interaction with seawater (which has an $^{87}Sr/^{86}Sr$ ratio of 0.7091) at the level of the magma chamber. However, in this case, a correlation between $^{87}Sr/^{86}Sr$ ratio and Sr content should be observed, which is obviously not the case (Table 1). In addition, Nd isotopes correlate negatively with Sr isotopes (Fig. 2*c*) and lie on the mantle array. As seawater contamination affects only Sr isotopes and in consequence shifts the points to the right of the mantle array, the present results can be considered indicative of large strontium and neodymium mantle heterogeneity beneath these islands. These data also have a bearing on the genesis of the volcanism within each of the islands: on each, the rocks have isotopic compositions indicating that they cannot have originated from a single primary basaltic melt by a fractional crystallization; either they originate from distinct mantle sources separated for more than 1,000 Myr or they result from the mixing in different proportions of a MORB-type source and of an enriched source. In either case, fractional crystallization occurring in the magma chambers may modify elemental concentrations.

Although each belongs to a separate magmatic suite, the five analysed samples from Tubuaii have remarkably similar Sr, Pb and Nd isotopic compositions. The $^{87}Sr/^{86}Sr$ ratios of 0.70278 (a value comparable to those of Ascension, St Helena and Galapagos[27,30–32] are among the lowest reported for an oceanic island. In contrast, the $^{206}Pb/^{204}Pb$ of 21.10 and the $^{208}Pb/^{204}Pb$ of 40.35 are the highest reported for an oceanic island. Of published data, St Helena has the most similar composition, with $^{206}Pb/^{204}Pb$ ratios ranging between 20.70 and 20.91 and $^{208}Pb/^{204}Pb$ from 40.00 to 40.16 [33].

Both in Nd/Sr and Sr/Pb diagrams (Fig. 2*c*, *d*) the Tubuaii data plot very close to the St Helena data. This shows that the St Helena mantle source is not an exception and that beneath both the South Atlantic and South Pacific oceans, the same kind of peculiar mantle region exists. Zindler *et al.*[34] propose that the St Helena data indicate a mixture of depleted mantle and recycled oceanic crust, the latter having had a low Rb/Sr ratio, relatively high Sm/Nd and high U/Pb ratio for a long period of time. Low Rb/Sr and $^{87}Sr/^{86}Sr$ for the recycled oceanic crust seem unlikely since Hart and Staudigel[35] consider that alteration increases both the Rb content and the Sr isotopic composition of the oceanic crust. However, Michard *et al.*[36] present data on the East Pacific Rise black smokers which shows that the hydrothermal fluid circulation within the oceanic crust may drastically reduce the Rb content of the oceanic crust and increase its U content. If the effects of the hydrothermal alteration are large enough to counteract the increase of the Rb/Sr ratio due to the addition of sediments and to the superficial seawater alteration, then the Rb/Sr ratio of the altered oceanic crust could decrease to below its original value.

If such a decrease of the global Rb/Sr ratio of the altered crust is realistic, data such as those obtained in St Helena and Tubuaii can be explained by melting of a recycled oceanic crust. An alternative explanation for having a mantle source with long time-integrated low Rb/Sr ratio as well as high U/Pb ratio, has already been proposed by Vidal and Dosso[3]. These authors proposed that part of the mantle has been depleted in Pb and Rb by extraction of those elements as sulphide phases from the lower mantle to the core. This could be the end-member close to the St Helena and Tubuaii data in the mantle plane.

The data now available for Marquesas and Tubuaii have two general implications regarding the mantle evolution. First, the particular mantle process which produced the St Helena source and which is still not well understood also took place beneath a portion of the Pacific Ocean, and second, the mantle is extremely heterogeneous beneath French Polynesia. Samples from a single island (Nuku Hiva) cover half the observed Sr-Nd isotopic variation in the oceanic islands, and in the three Marquesas islands studied here, almost the entire range is observed. On the scale of the whole of French Polynesia, more than half of the Pb isotope field is observed. These observations suggest that the large number of Polynesian islands scattered over a very large area offer a unique opportunity to study the scales

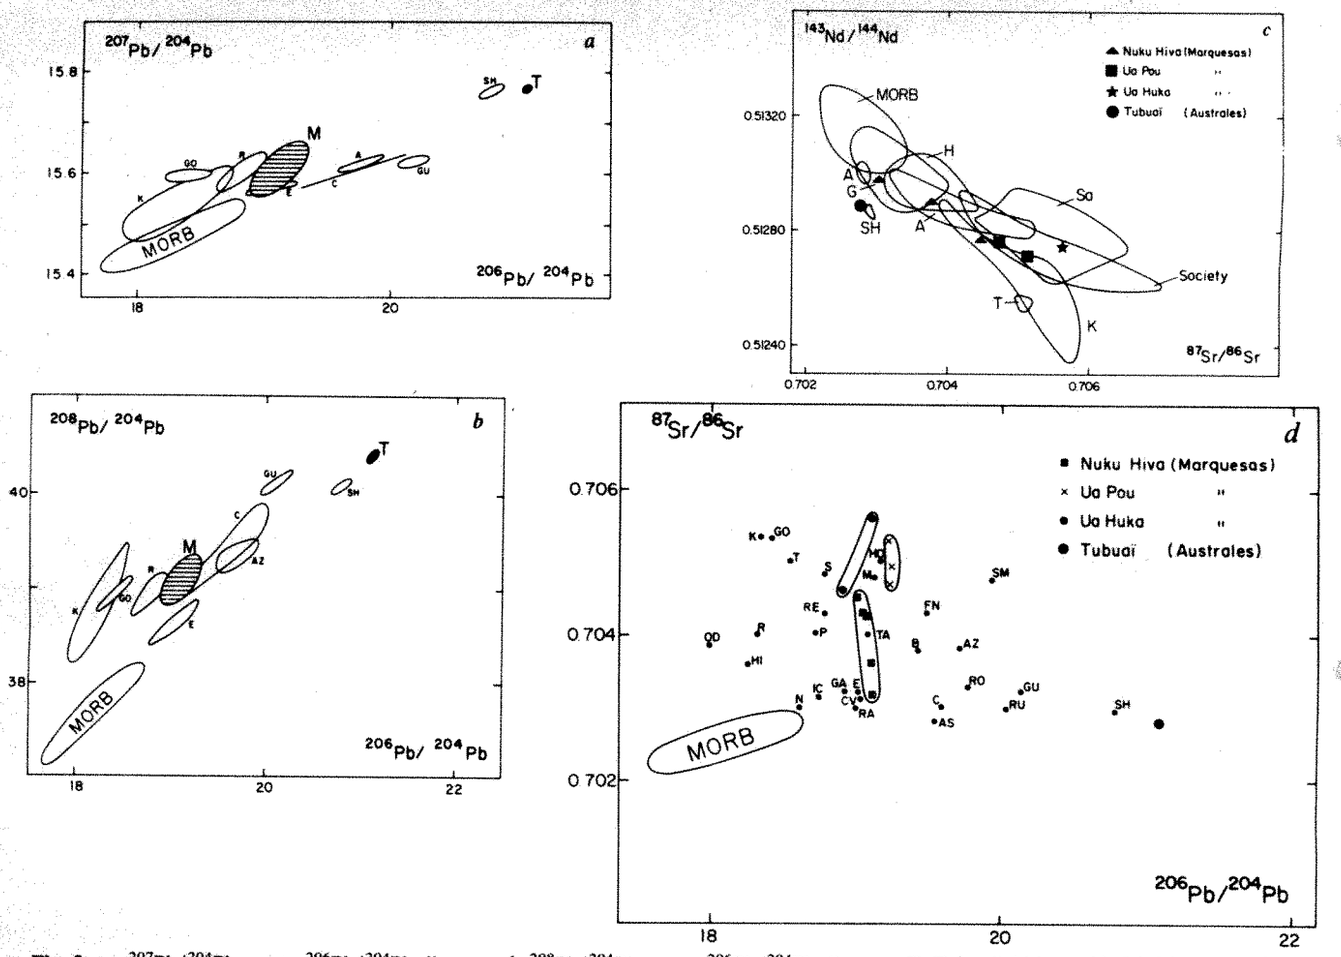

Fig. 2 *a*, $^{207}Pb/^{204}Pb$ versus $^{206}Pb/^{204}Pb$ diagram; *b*, $^{208}Pb/^{204}Pb$ versus $^{206}Pb/^{204}Pb$ diagram. T, Tubuaii (this work); M, Marquesas (this work); other data are from the literature. SH, St Helena; GU, Guadalupe; AZ, Azores; C, Canary; E, Easter; R, Reunion; GO, Gough; K, Kerguelen. *c*, $^{143}Nd/^{144}Nd$ versus $^{87}Sr/^{86}Sr$ diagram. Data from this work are represented by symbols; other data[27,32,37–42] are only shown by fields. *d*, $^{87}Sr/^{86}Sr$ versus $^{206}Pb/^{204}Pb$ diagram. In order to simplify the figure, an average of all data available for each island has been done as already suggested by Zindler *et al.*[34]. Data are from the compilation made by Sun[33] with the exception of Fernando de Noronha (F.N.), which are unpublished data of Ph.V. and G. Cornen. Abbreviations as follows: K, Kerguelen; GO, Gough; T, Tristan de Cunha; S, Samoa; HO; Hiva Oa; M, Moorea; SM, Sao Miguel; RE, Reunion; P, Penhu; TA, Tahiti; B, Bouvet; AZ, Azores; GA, Galapagos; SH, St Helena; GU, Guadalupe; RU, Rurutu (Australes); RO, Ross; C, Canary; AS, Ascension; RA, Rapa (Australes); CV, Cape Verde; E, Easter; N, Nunivak; IC, Iceland; OD, Oki Dogo; R, Rarotonga; HI, Hawaii.

of mantle heterogeneities. In particular it is striking that each of the three Marquesas islands studied has a unique Pb composition, whereas Sr and Nd vary greatly.

We conclude from our observation first that the volume of the mantle involved in the generation of the lavas observed in one island might, in the case of an idealized cubic volume, have a side smaller than a few tens of kilometres, and second that large Sr and Nd heterogeneities might have persisted on this rather restricted scale over thousands of millions of years. In fact, the actual heterogeneities might be smaller, since the spread defined by the data in the Sr against Nd diagram can be due to a mixing between two sources: the first being time-integrated enriched in incompatible elements, and the second being a MORB-type source.

We thank F. Albarède and A. W. Hofmann for help in preparing the manuscript and Bill White for his review. Part of this work was supported by CNRS ATP Transferts (Contract 15–14).

Zooplankton faecal pellets are important in the vertical transport and exchange of elements in the oceanic ecosystem[1,2]. Although microbial, and in particular bacterial, processes have been implicated in the decomposition of aquatic faecal pellets[3–7], few quantitative data exist on the metabolic activities and growth characteristics of the associated microorganisms. As part of the Vertex (Vertical Transport and Exchange) programme, we studied these aspects using field-collected faecal pellets of known source and age. Our results, reported here, show that microbial biomass and metabolic activity are highest at the time of egestion, and decline with subsequent incubation. An independent observation from these experiments was the detection of bioluminescence in freshly excreted faecal pellets and in materials collected from sediment traps. These field data support an existing model for the ecological role of bacterial light emission in the mesopelagic zone of the ocean.

In the present study, freshly produced copepod faecal pellets were incubated in sterile filtered seawater in temperature-controlled conditions. Changes in ATP biomass, RNA and DNA synthesis rates (as measures of total microbial production and cell division) and bioluminescence were monitored with time. The data (Fig. 1) show that rates of RNA and DNA synthesis were highest at the time of egestion and decreased with subsequent ageing. Since nucleic acid synthesis rates are positively correlated with cellular biosynthesis[8–10], it can be concluded that both growth and cell division decreased with time. After 48 h, the RNA synthesis rate was 22% of the initial rate and the DNA synthesis rate had decreased to less than 3% of the original value. Two additional experiments, performed over 96 h, confirmed that microbial rate processes decreased with faecal pellet age. Total microbial biomass (as determined from faecal pellet ATP concentrations) was more variable among experiments. However, in no case was there evidence for an overall increase in the total microbial population during the incubation periods (up to 120 h). ATP values for fresh copepod faecal pellets in these experiments ranged from 70 to 1,156 ng per mg dry weight.

Although low temperatures have been related to decreases in metabolic activity and rates of faecal pellet degradation[5,11], there was no apparent response to temperature changes in our experiments. Pellets, aged at a constant temperature of 19° C, showed reductions in rates of RNA and DNA synthesis similar to those of faecal pellets aged as described in Fig. 1 legend.

The decreases we observed in the above experiments were unexpected as the present scenario for faecal pellet breakdown requires that the associated microbial populations exhibit rapid growth and division. Indeed, Honjo and Roman[4] observed that degradation of the surface membrane of laboratory-produced copepod pellets began within 3 h and was complete after 24 h. The implication that faecal pellets are colonized and degraded by external microbial populations is derived from time-course electron microscopic studies of pellet surfaces[3–5]. In our study, however, the high biomass, metabolic activity and luminescence (see below) associated with field-collected faecal pellets at the time of egestion indicated the presence and importance of gut-derived microflora. Furthermore, we were unable to detect any major differences between faecal pellets incubated in sterile filtered seawater and in unfiltered seawater. Recent transmission electron microscopic observations of thin sections from copepod faecal pellet interiors[7] also suggest that internal microbial communities have a major role in faecal pellet breakdown.

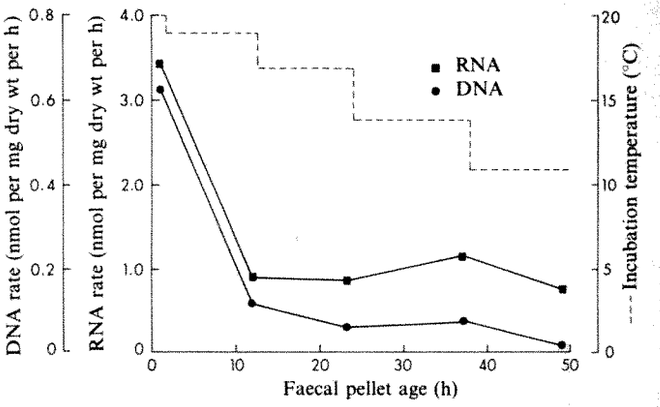

Fig. 1 Changes in rates of RNA and DNA synthesis as a function of faecal pellet age. Fresh faecal pellets from net-collected copepods were obtained by the method of La Rosa[29] as modified by Small *et al.*[13]. Known volumes of pellets, retained on a 68 μm Nitex net, were rinsed with distilled water, dried and weighed using a Cahn electrobalance. Faecal pellet material was also diluted 20-fold with 64 μm Nitex-filtered seawater and replicate 1-ml and 0.1-ml aliquots were incubated in small glass vials. The glass vials were moved through a temperature gradient with time (20–11 °C) to simulate the *in situ* conditions that sinking pellets would encounter. The rate at which the vials were rotated was determined by combining pellet sinking rate data[13] with the temperature regime of the water column. At selected times during the experiment, a 1-ml vial was incubated with 20 μCi ml^{-1} (final concentration) of [2-^{3}H]adenine (15.5 Ci $mmol^{-1}$; NEN) for 1 h, after which determinations of rates of RNA and DNA synthesis[30,31] and ATP[32] were made. Vials containing the 0.1-ml aliquots were filtered onto a combusted glass fibre filter and analysed for organic carbon, using a Perkin-Elmer CN analyser, throughout the incubation period. Faecal pellets were also aged in 0.22-μm Millipore-filtered seawater to assess contamination from planktonic bacteria. No differences in nucleic acid synthesis rates or ATP concentrations were observed between pellets incubated in 68 μm and in 0.22 μm-filtered seawater.

Oceanic zooplankton, grown in conditions of food limitation, are known to have higher assimilation efficiencies than coastal plankton or laboratory cultures maintained with high food concentrations[12]. Major differences between faecal pellets produced by the two groups have been noted[13]. Microbiological activity may similarly depend on the quality, compaction and composition of the egested pellets. Carbon analyses of our source-term pellets revealed that between 12 and 27% of the faecal pellet mass was organic carbon, which is in agreement with published data[4,5,14]. However, 50–100% of this organic carbon was living carbon as estimated from our ATP data (using an average C:ATP ratio of 250 (refs 15, 16)). It seems that reduced carbon sources may be insufficient to support the active growth and division of chemoheterotrophic microbial populations and that these organisms substantially reduce their metabolic activity soon after the pellets are voided. This is consistent with the previous observation that faecal pellets produced by euphausiids feeding on natural food sources can remain intact for weeks at temperatures as high as 18 °C (ref. 17).

In vivo bioluminescence, detected with a shipboard photometer, occurred in 70% of all samples surveyed including sediment trap-collected particulate matter, freshly collected zooplankton faecal pellets, crustacean molts, live animals (such as euphausiids, copepods, amphipods, etc.), and particulate detritus collected with plankton nets and water samplers. Long-term kinetics (s to min) revealed two distinct patterns of light emission, possibly reflecting various sources of luminescence. Erratic, luminous flashes predominated in the live animal and

Table 1 Vertical distribution of bioluminescence and ATP from particle interceptor traps (VERTEX II)

Depth (m)	Total sediment trap bioluminescence (10^5 photons cm^{-2} s^{-1})	Total sediment-trap ATP (μg)	Specific bioluminescence (photons cm^{-2} s^{-1} per pg ATP)
30	17.2	1.30 (0.296)	1.32
120	3.39 (0.024)	2.09 (0.172)	0.167
200	2.96 (0.041)	2.52 (0.235)	0.117
400	1.21 (0.022)	1.04 (0.094)	0.116
700	1.30 (0.023)	0.742 (0.161)	0.175
800	1.11 (0.009)	0.833 (0.067)	0.133
900	1.36 (0.020)	0.083 (0.025)	1.64
1,400	1.33 (0.027)	0.068 (0.002)	19.6
1,900	1.52 (0.008)	0.008 (0.010)	18.6

Free-floating MULTITRAP design particle traps[26] were deployed approximately 100 km off the western coast of Mexico (17°8′ N, 109°0′ W) from 27 October to 17 November 1981. The light emission (integrated over 1 min) from a known volume of sediment-trap material, was recorded using an SAI model 2000 ATP photometer set at maximum sensitivity. Mean values ($n = 3$) scaled to total trap volume are reported (±1 s.d.). The phototube detector was calibrated using a standard light source (Optronic Laboratories, Inc. lamp 245 C) and a US National Bureau of Standards traceable photodiode (United Detector Technology silicon photodiode, PIN 10DSB). The spectrum of light from the lamp was regulated by a Melles Griot wide-band filter (03F1B003) with peak transmission at 440 nm and full-width half maximum of 85 nm. The specific bioluminescence measured from a luminescent bacterial culture, *Photobacterium leiognathi* strain 721 (ref. 27), at maximum light intensity ($A_{660} = 0.54$) was 2.22×10^3 photons per cm^2 per s per pg ATP. Total sediment-trap ATP biomass was measured according to the methods of Karl and Knauer[28].

net plankton samples, whereas sediment-trap particles and faecal pellets characteristically showed a continuous and steady light output. The former response has been reported for certain species of dinoflagellates, copepods, euphausiids and planktonic larvae. The duration of these individual flash events is generally of the order of tens (or hundreds) of milliseconds[18–20]. On the other hand, light emission from luminescent bacteria is continuous, even in single cells, and exhibits neither flashes nor oscillations[21]. Our observations suggest that enteric marine luminous bacteria are responsible for the light emission from faecal pellets, and possibly from materials collected in the sediment traps also. Recent data from a subsequent Vertex field experiment, near the same site, confirm this hypothesis. Luminescent bacteria have been isolated from sediment-trap materials and source-term faecal pellets and the *in situ* light emission has been shown experimentally to be of bacterial origin (C.C.A. and D.M.K., in preparation).

The bioluminescence of particulate matter collected in sediment traps was greatest at 30 m, diminished rapidly to less than one-third of this value by 120 m, and gradually decreased to a constant level with depth (Table 1). Interestingly, when light emission per unit biomass is examined (that is, 'biomass-specific' luminescence), the depth profile exhibits a distinct increase below 800 m (Table 1); this may have been a direct effect of the endogenous control of *in vivo* bioluminescence resulting from specific changes in environmental conditions such as oxygen or nutrient concentrations[22,23]. The increase may also have been caused by an overall shift in the species composition favouring the succession of luminous bacteria at depth. A more likely explanation, however, is a direct relationship to the production and downward vertical flux of particulate matter. The observed increase in biomass-specific luminescence below 800 m correlates with the zone of enhanced biological activity and new particle production found just beneath the O_2 minimum (0.1–0.25 ml O_2 per litre). At 800 m, microbial rate processes associated with sediment trap-collected particles were maximal (D.M.K., unpublished) and within the water column, there was a substantial increase in the standing stock of nauplii and in total plankton dry weight (G. Knauer and M. Tuel, personal communication). Furthermore, stimulated *in situ* bioluminescence measured in the water column at the same station also showed increasing (but sporadic) activity below 700 m (ref. 24). These supplementary observations suggest that freshly produced pellets, at 800 m, may account for the greater particle bioluminescence at 900 m and below. It is conceivable that *in situ* measurements of bioluminescence, especially those which are associated with sinking particles, may be used for detecting the input of fresh organic detritus at intermediate oceanic depths.

The fact that copepod faecal pellets, as well as other particulate materials, are luminescent suggests an important relationship between feeding and light in the trophic structure of the mesopelagic realm. It also provides field support for the hypothesis that the functional importance of luminescence in marine bacteria[22,25] is related to the dispersion and propagation of bacterial species. If faecal pellet microbial populations are generally inactive once the pellets are voided into the water, as suggested by this work, then bacterial decomposition would be insufficient for remineralization to occur during descent of the pellets. Slow decomposition combined with rapid settling rates would result in the loss of large quantities of carbon and energy-rich particles to the benthos. Direct feeding on these sinking bioluminescent particles by organisms from higher trophic levels may ensure against such loss and facilitate the propagation of bacterial species.

We thank G. Knauer and M. Tuel for providing their unpublished Vertex zooplankton data, S. Moore for faecal pellet carbon analyses, J. La Rosa for technical assistance, and the scientists and crew of the RV Wecoma (Vertex II) for their assistance in sample collection. D. O'Connor kindly provided the instrumentation and expertise for the calibration of our photometer. This research was supported by NSF grants OCE80-05180 (to D.M.K.) and OCE79-2321 (to L.F.S.). The International Laboratory of Marine Radioactivity is operated under a tripartite agreement between the International Atomic Energy Agency, the Government of Monaco and the Oceanographic Institute at Monaco.

Positional determination of supernumerary blast cell death in the leech embryo

M. Shankland

Department of Molecular Biology, University of California, Berkeley, California 94720, USA

Segmented animals are divided into a longitudinal array of developmentally homologous subunits known as metameres. The embryonic origin of the segmental body plan has been studied in a variety of organisms, with particular emphasis on the mechanisms underlying the delineation of the individual metameres[1–3] and their secondary diversification[4]. I have examined the embryonic events which determine the total number of segments in the glossiphoniid leech *Helobdella triserialis*. The germinal band of the leech consists of chains of segmental founder cells, called blast cells, and is normally reduced to 32 segments by the degeneration of supernumerary blast cells located at its caudal end[5,6]. By using a novel technique for selective cell ablation, the segmental register of the four ectodermal cell lines can be altered so that lineally identifiable blast cells take part in the formation of ectopic segments. I show here that the survival or death of ectodermal blast cells is determined by position independent of their cell lineage identities, implying that the final number of segments is imposed on the ectoderm by interactions with the other embryonic tissues.

The egg of the glossiphoniid leech develops directly into the adult form through a stereotyped sequence of cell divisions[7,8], with the metameric portion of the ectoderm and mesoderm deriving from five bilateral pairs of blastomeres known as the M, N, O, P and Q teloblasts (Fig. 1). Each teloblast undergoes several dozen asymmetric divisions to generate a germinal bandlet—a chain of much smaller primary blast cells which will be designated here by the lower case letter corresponding to their teloblast of origin (Fig. 2*a*). On either side of the embryo the five bandlets come together in parallel to form a unified germinal band, with the firstborn blast cells lying at the future rostral end. By injecting the various teloblasts with vital cell lineage tracers and following the fate of the labelled clones[9,10], it has been shown that each teloblast gives rise to a specific, hemilateral set of segmentally iterated tissues in the mature leech[8,11]. The present study focuses on the ectodermal bandlets o and p in which a single primary blast cell gives rise to one segmental complement of the tissues descended from its teloblast (D. A. Weisblat, in preparation).

The leech's segmental body plan can be envisioned as a two-dimensional array of blast cells in which one dimension—teloblast of origin—is related to the cellular composition of the descendent clone, while the second dimension—birth rank within the bandlet—dictates the rostrocaudal position, that is, the segmental fate of the clone. This strict correlation between a cell's genealogy and its fate suggests that individual blast cells follow distinct developmental pathways as a direct result of their cell lineage identities. The developmental importance of the teloblast of origin has been established by studies in which particular teloblasts were ablated by injecting them with toxic enzymes[12,13], although an instance of positional determination has also been found[14]. To discover whether birth rank is responsible for segment-specific differences in blast cell development, I devised an experimental procedure involving the selective ablation of small groups of blast cells which cause cells in the remainder of the bandlet to take part in the formation of segments for which they are not normally destined.

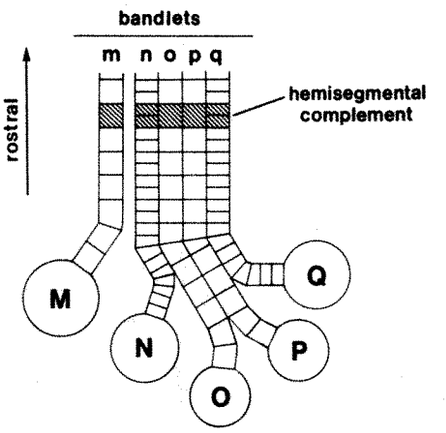

Fig. 1 Schematic diagram of germinal band formation in the leech embryo, taken from D. A. Weisblat (in preparation). The segmental tissues consist of five cell lines descended from the M, N, O, P and Q teloblasts. Each teloblast generates a bandlet of much smaller primary blast cells, and the five bandlets come together in parallel to form a unified germinal band. For the purposes of this illustration the mesodermal m bandlet has been displaced from its normal location beneath the four ectodermal bandlets. Each hemisegmental complement of the mature body wall and nervous system is founded by a homologous ensemble of seven primary blast cells.

Being too small for the reliable injection of toxic agents, blast cells were ablated by means of a photosensitizing lineage tracer inherited from their parental teloblast. This tracer, FDX, consists of fluorescein isothiocyanate covalently linked to a 10,000-molecular weight dextran carrier molecule which prevents passage across gap junctions. FDX is thus confined to the descendants of the injected teloblast and, in normal lighting conditions, serves as a vital cell lineage tracer[10]. However, FDX-labelled cells are dramatically sensitized to radiant energy within the fluorescein absorption spectrum[15], and can be selectively ablated under an epifluorescence microscope using a ×40 water immersion objective and a 50 W mercury arc with narrow band exciter filter (peak transmittance 485 nm). Labelled cells were safely viewed while orienting the embryos by shielding the light source to 1% maximal intensity. The iris was then closed so as to illuminate a circular spot of 15 μm diameter, encompassing two primary blast cells, and the beam raised to maximal intensity for 20–60 s. This exposure bleaches a substantial fraction of the FDX fluorescence (Fig. 2*b*), and causes rapid degeneration of the labelled cells. The residual, unbleached tracer dissipates within 2–10 h after illumination (Fig. 2*c*), suggesting that the dying cells have lost their membrane integrity. In contrast, blast cells labelled with tracers which do not absorb at this wavelength can be illuminated for 300 s and still give rise to their normal descendent clones.

Photoablation of a patch of contiguous blast cells sunders the labelled bandlet into rostral and caudal fragments. If an o or p bandlet is lesioned just past the point where it merges into the germinal band, subsequent observations with low levels of illumination reveal that the caudal or trailing fragment is temporarily retarded from entering the band with a consequent widening of the gap produced by the lesion (Fig. 3*a*). The retarded bandlet slips out of its normal segmental register as the neighbouring bandlets slide past, and the constituent blast cells come to occupy segments for which they are not normally destined.

To demonstrate that blast cells are slipping into ectopic segments, the caudal fragment of the lesioned bandlet was com-

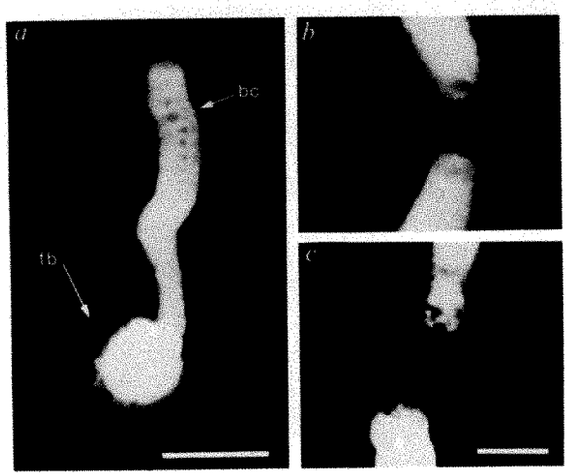

Fig. 2 Fluorescence micrographs of FDX-labelled germinal bandlets. *a*, The P teloblast (tb) has produced 20 labelled blast cell progeny (bc) 25 h after the injection of FDX. This tracer is excluded from the outer, yolky region of the teloblast cytoplasm, and from the blast cell nuclei. Scale bar, 50 μm. *b*, Localized photolesioning of an FDX-labelled bandlet after 60 s exposure of two primary blast cells to intense 485-nm illumination. The target cells can be recognized by the pronounced photobleaching of their FDX fluorescence, and have already begun to display an abnormal, rounded morphology within minutes of illumination. *c*, The dying blast cells, seen here in a different embryo 5 h after illumination, lose their residual, unbleached tracer, suggestive of a breakdown in membrane integrity. Scale bar, 10 μm.

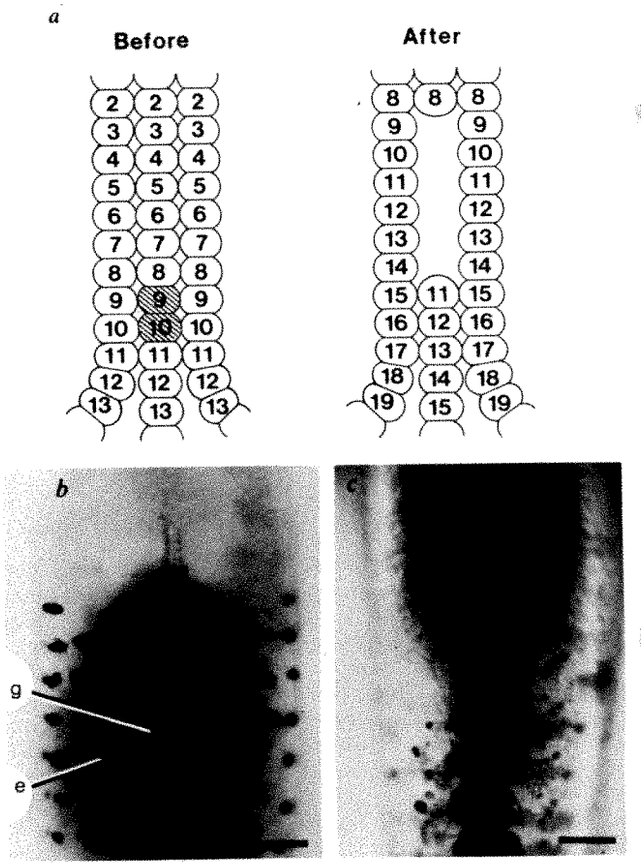

Fig. 3 Photolesioned ectodermal bandlets slip out of their normal segmental register. *a*, Schematic diagram showing the point where the germinal bandlets merge into the germinal band. Numbers represent blast cell birth ranks and thus correspond to their segments of normal destiny. If one of the bandlets is lesioned (cross-hatching) near its point of entry, the trailing portion of the bandlet is temporarily retarded and thereby slips posteriorly with respect to the other, unlesioned bandlets. *b*, Stage 10 embryo in which the right and left O teloblasts were simultaneously injected with HRP during stage 7, midway through blast cell production. Anterior is at the top. Because homologous teloblasts produce their blast cell progeny in virtual synchrony, there are an equal number of labelled segments on the two sides. Note the segmentally iterated pattern of labelled tissues, including patches of body wall epithelium (e) and clusters of neurones within the segmental ganglia (g). *c*, In this embryo the right and left O teloblasts were simultaneously injected with HRP after the o bandlet on the left had been photolesioned near its rostral end, that is, well in advance of the first HRP-labelled cells. The disparity in the anterior boundary of the HRP-labelled region on the two sides demonstrates that the lesioned bandlet has slipped four segments posteriorly. Despite the change in longitudinal register the slipped blast cells have given rise to the normal pattern of descendant tissues within their ectopic segments. Scale bar, 50 μm.

pared with its unlesioned contralateral homologue by means of secondary tracer injections. In a normal embryo the simultaneous injection of bilaterally homologous teloblasts with the lineage tracer horseradish peroxidase (HRP) gives rise to an equal number of labelled segments on the two sides of the mature leech (Fig. 3*b*). If the right and left O or P teloblasts are injected with HRP after having produced 10–25 primary blast cells, the anterior boundaries of the right and left labelled regions fall within the same segment in the majority of cases (82%, 28/34) and never lie more than one segment apart. In a series of 24 experimental embryos the O or P teloblasts were initially injected with FDX, then simultaneously reinjected with HRP after the formation of a dozen or so singly labelled blast cells. On the right side of the embryo the first 2–3 FDX-labelled blast cells were ablated as they entered the germinal band. When these embryos were examined later in development, it was found that there was a sequence of several midbody segments containing both FDX and HRP on the control side, but only FDX on the lesioned side. On the average the anterior boundary of the HRP-labelled region was located six segments (range 0–12) more posteriorly on the lesioned side (Fig. 3*c*), demonstrating that blast cells in the caudal fragment of the lesioned bandlet had failed to reach their normal segmental destinations.

If segmental differences arise from autonomous properties of the individual blast cells, then slipped blast cells should develop in accordance with their birth rank despite their ectopic location. For the present study attention was focused on the process of supernumerary blast cell death. Each teloblast gives rise to 5–15 more blast cells than are necessary to populate the 32 body segments[5,6], and the excess blast cells degenerate—as judged by the dissipation of intracellular lineage tracers—during the construction of the germinal band. This pattern of development could be determined solely on the basis of cell lineage if each teloblast first generates the appropriate number of viable blast cells, and thereafter only produces supernumerary blast cells which differ in a way that brings about their premature destruction. This hypothesis was tested by examining blast cell death at the caudal end of slipped o or p bandlets (Fig. 4*a*). In 17 cases it was found that a bandlet which had slipped 3–10 segments posteriorly began to degenerate at the same point (±1 primary blast cell clone) as the other unlesioned bandlets (Fig. 4*b*). Similar results were obtained following slippage of lesioned n bandlets, and the combined slippage of ipsilateral o and p bandlets. Assuming that the lesioned bandlet(s) slips uniformly—as suggested by the segmental disposition of its descendent tissues (Fig. 3*c*)—then those blast cells which would normally have inhabited the tail segments have degenerated like supernumeraries on slipping past the posterior end of the germinal band.

These results suggest that ectodermal blast cells will degenerate, regardless of their birth rank, if they fail to become incorporated into the first 32 segments. Due to the unidirectionality of slippage it is unknown whether blast cells whose birth rank

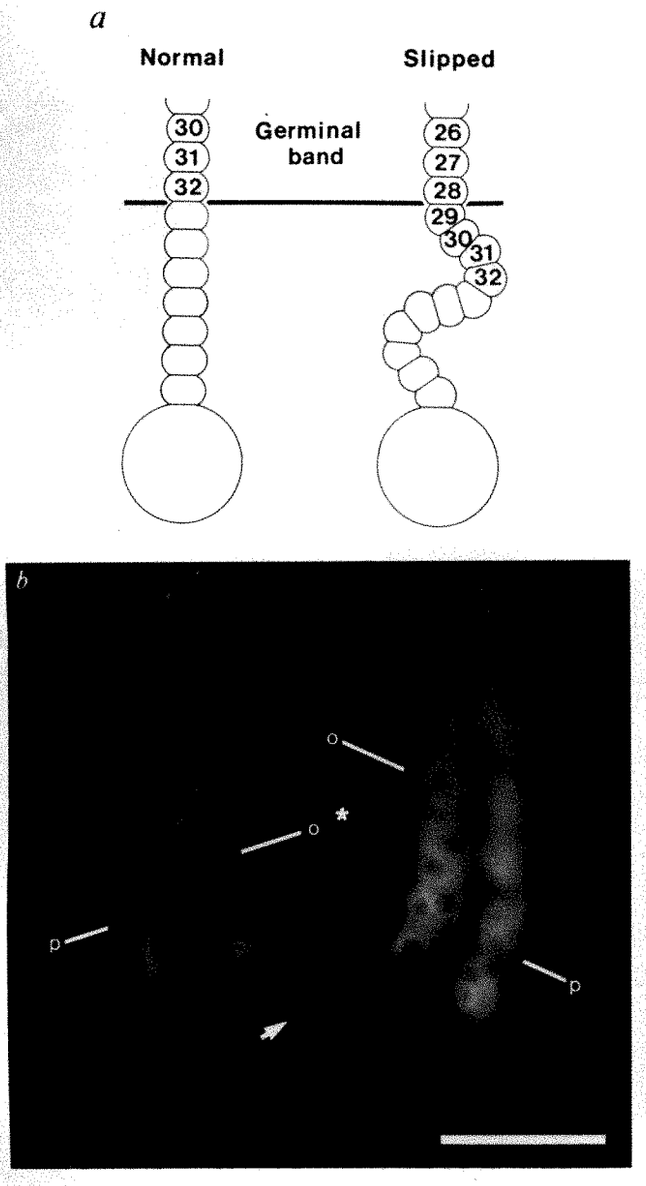

Fig. 4 Each teloblast produces several supernumerary blast cells which do not enter the germinal band and degenerate without giving rise to segmental tissue. *a*, If a lesioned bandlet slips posteriorly, those blast cells which would, on the basis of birth rank, normally inhabit the last of the 32 body segments will fail to enter the germinal band. *b*, Fluorescence micrograph of FDX-labelled o and p bandlets at the posterior end of the two germinal bands. In this stage 8 embryo the supernumerary blast cells have degenerated, leaving bits of fluorescent debris (arrow), and the incorporated blast cells have undergone secondary divisions to produce protosegmental clusters of daughter cells. The o bandlet on the left (labelled with an asterisk) was photolesioned near its rostral end and has slipped five segments posteriorly as measured by secondary tracer injection (not shown). This slipped bandlet terminates in register with the other, unlesioned bandlets, implying that position, not blast cell birth ranks, marks the point of transition between the surviving and dying blast cells. Scale bar, 50 μm.

normally renders them supernumerary would survive and proliferate if they entered the germinal band. Still it would seem that blast cell death can be determined solely by the cell's rostrocaudal position with respect to the germinal band as a whole. Thus, supernumerary blast cell death is probably brought about by interactions with the cellular environment, as has previously been shown for the 'programmed death' of certain lineally identified cells in the nematode[16,17]. Preliminary observations suggest that slipped ectodermal blast cells also exhibit host segment specificity in other aspects of their differentiation, for example the fusion of the seven most caudal neuromeres to form a compound tail ganglion.

It is not yet known how the supernumerary blast cells detect their position relative to the end of the germinal band. For the hirudinid leech embryo it has been proposed that the point of ectodermal bandlet termination is determined by the underlying mesoderm[6]. However, ectodermal blast cells can survive past the stage of supernumerary blast cell death in mesoderm-deficient germinal bands[12]. The role of the mesoderm was not examined in the present study because there was no apparent slippage following lesions of the m bandlet. Nonetheless, the present findings are consistent with the idea that the final length of the germinal band is fixed by some embryonic tissue or landmark other than the ectoderm, then subsequently imposed on the ectoderm by positionally determined death of the supernumerary blast cells.

I thank Gunther Stent, David Weisblat and David Bentley for critical reading of the manuscript. This work was supported by US PHS postdoctoral award 5 F32 NSO6814-02 and a grant from the Rowland Foundation.

Inverse relationship between neurotensin receptors and neurotensin-like immunoreactivity in cat striatum

M. Goedert, P. W. Mantyh, P. C. Emson & S. P. Hunt

MRC Neurochemical Pharmacology Unit, Medical Research Council Centre, Medical School, Hills Road, Cambridge CB2 2QH, UK

The adult corpus striatum in mammals is divided into distinct histochemical compartments[1]. If the cat caudate nucleus is stained for acetylcholinesterase a number of macroscopically visible zones appear that have lower acetylcholinesterase activity than the surrounding tissue[2]. These patches, called 'striosomes'[1], correspond to regions of high [Met]-enkephalin-like immunoreactivity[3] and dense opiate receptor binding[4] and are related to the uneven distribution of striatal efferent neurones and cortical afferent terminations[5,6]. One of the highest concentrations of neurotensin-like immunoreactivity is in the striatum and the immunoreactive material co-elutes with synthetic neurotensin on gel chromatography[7]. Recently, we have found that neurotensin-like immunoreactivity in the cat caudate nucleus coincides with the striosomes[8]. We have now localized neurotensin receptors in the cat caudate nucleus by autoradiography[9] and found low density in the neurotensin-rich striosomes and a high density in the neurotensin-poor surrounding tissue.

Adult male cats received a lethal injection of pentobarbitone; their brains were removed and immersed in ice-cold saline for 10 min. Blocks containing the corpus striatum were frozen and sectioned in the transverse plane at 20 μm using a cryostat. Adjacent sections were incubated with either 2 nM ^{3}H-

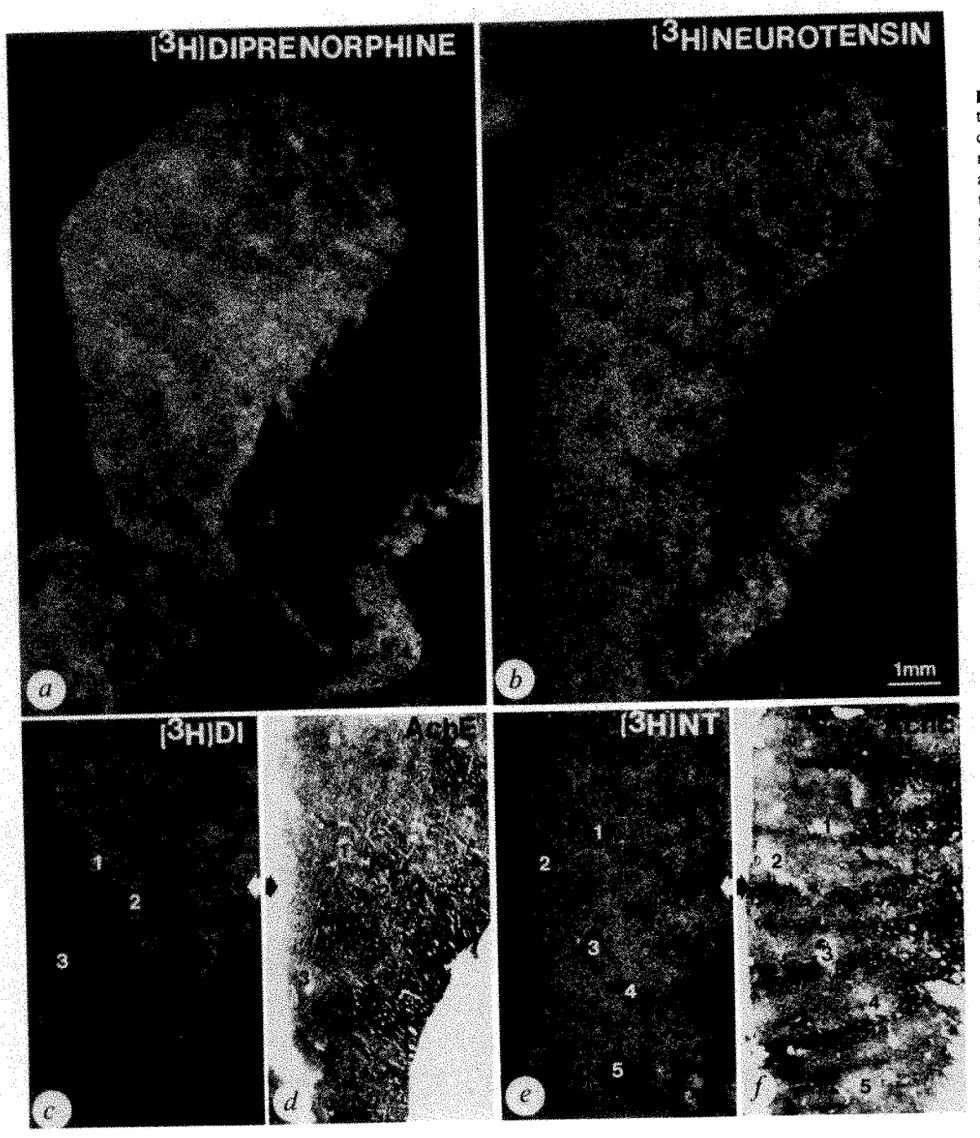

Fig. 1 Autoradiography of ^{3}H-neu tensin and ^{3}H-diprenorphine in cat caudate nucleus. *a*, *b*, The caud nucleus labelled with ^{3}H-diprenorph and ^{3}H-neurotensin respectively; *c*, *d*, s tion labelled with ^{3}H-diprenorphine stained for acetylcholinesterase; *e*, *f*, s tion labelled with ^{3}H-neurotensin stained for acetylcholinesterase. numbers in *c*–*f* refer to the ace cholinesterase-poor striosomes. Note correspondence between striosomes dense ^{3}H-diprenorphine labelling and inverse relationship between striosor and ^{3}H-neurotensin binding sites.
Methods: Sections (20 μm) containing cat striatum were pressed onto gela coated slides, melted in place, dried ov night at 4 °C and stored at −20 °C 24 h. Control experiments had establis that there was no detectable neuroten or [Met]enkephalin-like sections. thawed sections were incubated for 10 at 25 °C in 2 nM ^{3}H-neurotensin (I England Nuclear) in 50 mM Tris-H *p*H 7.40, containing 0.1% bovine se albumin, 40 mg l^{-1} bacitracin and 1 EDTA. Adjacent sections were incub for 40 min at 25 °C in 4 nM ^{3}H-dipre phine (Amersham), as described viously[12]. Non-specific binding was mated in parallel incubations in the p ence of 1 μM neurotensin (Cambr Research Biochemicals) or 1 naloxone (Endo). Following the inc tion the sections were washed twic ice-cold buffer (2 min each time), di into ice-cold water and dried und stream of cold air. They were arranged in X-ray cassettes, covered i dark-room with a tritium-sensitive (^{3}H-Ultrofilm, LKB) and kept at −2 for 6 weeks. Film was developed u safe-light conditions using Kodak D developer. Tissue sections were staine acetylcholinesterase[10].

neurotensin or 4 nM ^{3}H-diprenorphine. Nonspecific binding was defined as binding in the presence of 1 μM neurotensin or 1 μM naloxone. The sections were apposed to a tritium-sensitive film and kept at −20 °C for 6 weeks. The film was then developed and the tissue sections stained for acetylcholinesterase[10]. Test-tube binding of ^{3}H-neurotensin was performed using washed membranes from the cat caudate nucleus.

When sections of the striatum were incubated with ^{3}H-neurotensin an irregular distribution of silver grains was noted: whereas most of the caudate nucleus was labelled, local patches of sparse labelling occurred (Fig. 1*b*). No labelling was observed in the presence of 1 μM neurotensin. When the same sections were stained for acetylcholinesterase the regions rich in neurotensin binding sites (Fig. 1*e*) corresponded to acetylcholinesterase-rich regions (Fig. 1*f*). The neurotensin binding sites were further characterized using a test-tube binding assay for ^{3}H-neurotensin performed on washed membranes of the cat caudate nucleus. The binding was saturable (Fig. 2*a*) and Scatchard analysis indicated a single population of binding sites with a dissociation constant (K_D) of 1.54 nM and a maximum number of binding sites (B_{max}) of 68 fmol per mg protein (Fig. 2*b*). The competitive inhibition of ^{3}H-neurotensin binding by neurotensin appeared to be monophasic with a Hill coefficient not significantly different from 1 (Fig. 2*c*). The relative potencies of various neurotensin fragments in displacing ^{3}H-neurotensin were consistent with the potency obtained for these fragments in biological assays[11] (Tal indicating that the binding properties of ^{3}H-neurotensi consistent with the binding to a physiological neurotensin tor. When sections of the cat striatum were incubate ^{3}H-diprenorphine which labels all opiate receptor subty the concentration used[12], local patches of dense labelling e ded in a less dense background were observed (Fig. 1*a* labelling pattern was completely abolished in the prese 1 μM naloxone. When stained for acetylcholinestera regions rich in ^{3}H-diprenorphine receptors (Fig. 1*c*) co with the acetylcholinesterase-poor striosomes (Fig. 1*a* results obtained by histochemistry and receptor autora phy were further evaluated using microdensitometry (Ta The neurotensin- and [Met]-enkephalin-like immun tivities were six times more concentrated in the striosom in the surrounding tissue, whereas the neurotensin re were higher by 25% in the tissue around the strioson the opiate receptors 20% more numerous within the stric The acetylcholinesterase staining was 30% higher in th striosomal tissue.

The present findings indicate that neurotensin recept unevenly distributed throughout the caudate nucleus adult cat with areas of dense labelling corresp to acetylcholinesterase-rich regions. This contrast

Table 1 Inhibition of specific ^{3}H-neurotensin binding to cat caudate nucleus membranes by neurotensin fragments

Peptide	IC_{50}(nM)	Relative potency %
NT_{1-13}	2.80	100
NT_{8-13}	2.60	107
NT_{9-13}	265	1.1
NT_{10-13}	>10,000	<0.04
NT_{1-6}	>10,000	<0.04
NT_{1-8}	>10,000	<0.04
NT_{1-11}	>10,000	<0.04

The binding of tritiated neurotensin (NT) was assayed at a concentration of 2 nM. IC_{50} was defined as the concentration of unlabelled peptide required to inhibit the specific binding of ^{3}H-neurotensin by 50% and it was derived from the Hill transformation of the displacement curves. Similar IC_{50} values were obtained in three separate experiments. The relative potencies were calculated by comparing the IC_{50} values with that of NT_{1-13}. NT_{9-13} and NT_{10-13} were synthesized by Dr B. Williams (MRC Neurochemical Pharmacology Unit), NT_{8-13} was purchased from Peninsula Laboratories and all other peptides were obtained from Cambridge Research Biochemicals.

Table 2 Relative distribution of acetylcholinesterase activity, [Met]-enkephalin-like immunoreactivity, neurotensin-like immunoreactivity, opiate receptors and neurotensin receptors in striosomes and background matrix of the cat caudate nucleus

	Striosomes	Background matrix
Acetylcholinesterase	100 ± 3.10%	129.55 ± 4.38%*
[Met]-enkephalin-like immunoreactivity	100 ± 6.18%	14.00 ± 3.77%*
^{3}H-diprenorphine binding	100 ± 4.77%	81.41 ± 5.01%†
Neurotensin-like immunoreactivity	100 ± 11.52%	16.12 ± 7.05%*
^{3}H-neurotensin binding	100 ± 0.85%	125.75 ± 1.81%*

Striosomes and background matrix of the dorsal anterior part of the cat caudate nucleus (where the striosomal organization is the most marked) stained for acetylcholinesterase, [Met]-enkephalin- or neurotensin-like immunoreactivity[8] and incubated with ^{3}H-diprenorphine or ^{3}H-neurotensin were quantitatively assessed by using microdensitometry, as described previously[21]. The intensity in staining in the striosomal region was arbitrarily defined as 100% and the staining in the matrix expressed relative to it. Background staining for the immunohistochemistry and receptor binding was obtained from adjacent absorption control sections and subtracted for both striosomes and background matrix. For acetylcholinesterase background was taken to be the staining present in the internal capsule. The results represent the mean ±s.e.m. ($n = 5$).

* $P < 0.001$; † $P < 0.05$.

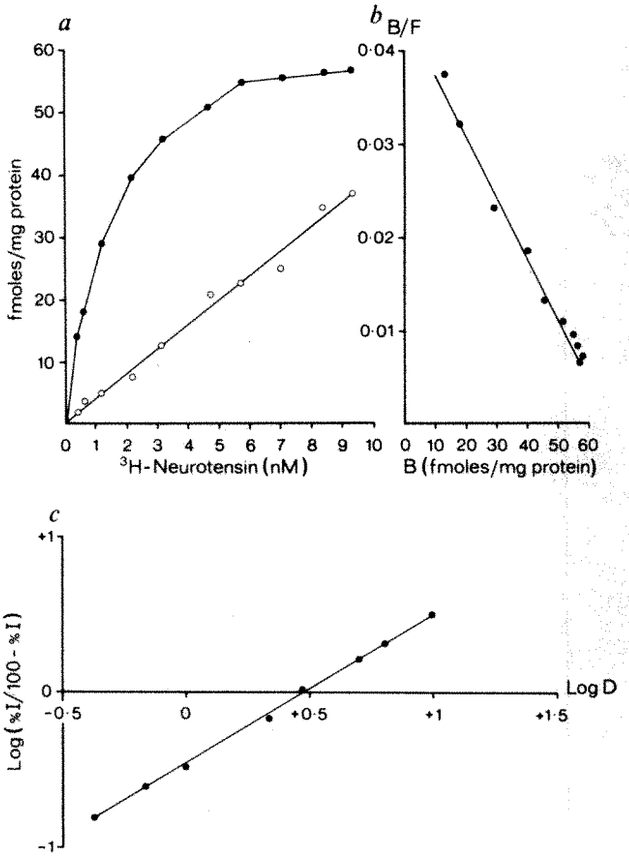

Fig. 2 ^{3}H-neurotensin binding to a membrane preparation of the cat caudate nucleus. *a*, ^{3}H-neurotensin binding as a function of the radiolabelled peptide concentration. Values were obtained in a single experiment. Similar results were obtained in four separate experiments. *b*, Scatchard plot of specific ^{3}H-neurotensin binding data. *c*, Hill transformation of ^{3}H-neurotensin binding by increasing concentrations of unlabelled neurotensin. A typical experiment is shown; similar results were obtained in four separate experiments.

Methods: The caudate nucleus from adult cats was homogenized in 10 volumes (w/v) of ice-cold 50 mM Tris-HCl, *p*H 7.40, with a Polytron at setting 7 for 15 s. After 20-min centrifugation at 50,000*g* the pellet was resuspended in 10 volumes of 50 mM Tris-HCl, incubated at 37 °C for 30 min and centrifuged again. The washed pellet was resuspended in 50 mM Tris-HCl, *p*H 7.40, containing 0.1% bovine serum albumin, 40 mg l^{-1} bacitracin and 1 mM EDTA to yield a concentration of 10 mg tissue per ml buffer. One ml of homogenate was incubated in the presence of ^{3}H-neurotensin (New England Nuclear) at 25 °C for 10 min. Non-specific binding (○) was defined as binding in the presence of 1 μM neurotensin and specific binding (●) was obtained by subtracting the nonspecific from the total binding. At the end of the incubation period the tubes were transferred onto ice and filtered immediately under reduced pressure through GF/B glass fibre filters (Whatman) pretreated with 0.2% polyethyleneimine (Sigma) in water. Each of the filters was washed four times with 5 ml ice-cold buffer and radioactivity determined by liquid scintillation spectrometry. A detailed characterization of the binding assay will be published elsewhere[22]. Proteins were determined according to Lowry *et al.*[23] using bovine serum albumin as the standard.

neurotensin-like immunoreactivity which is distributed like the previously described striosomes[8] defined by a low acetylcholinesterase activity and a high content of enkephalin-like immunoreactivity[1]. In the rat[4], opiate receptors coincide with [Met]-enkephalin-like immunoreactivity in the caudate nucleus. Lesion studies have indicated that rat opiate receptors are located on both intrinsic striatal neurones and dopamine-containing terminals, the receptor patches being mainly located in striatal neurones[13,14]. Similarly, we have found that 60% of rat striatal neurotensin receptors are localized on neurones intrinsic to the striatum[15].

The reason for the inverse relationship between neurotensin receptors and neurotensin-like immunoreactivity is unknown at present. Possibly, it could arise from different rates of turnover of neurotensin-like immunoreactivity in striosomes as compared to acetylcholinesterase-rich regions. Such regional differences have been observed for the turnover of dopamine in the rat striatum[16]. Discrepancies between the localization of either classical neurotransmitters or neuropeptides and their respective receptors have been noticed before. For instance, there exists a mismatch between noradrenaline levels and beta-adrenergic receptor numbers in the rat striatum[17,18] and between the content of substance P-like immunoreactivity and the number of substance P receptors in the rat substantia nigra[19,20]. Our present finding that neurotensin-like immunoreactivity and neurotensin receptors have different topographical localizations within an anatomical structure characterized by distinct histochemical compartments may have general implications for the function of basal ganglia.

We thank Dr B. Williams for two of the neurotensin fragments and Chloë Brown and Dr I. L. Martin for many helpful discussions. M.G. is supported by the British Council and P.W.M. is a NIH fellow.

Suppression of sprouting at the neuromuscular junction by immune sera

M. E. Gurney

Department of Pharmacological and Physiological Sciences, University of Chicago, 947 East 58th Street, Chicago, Illinois 60637, USA

Injury of afferent motor axons or pathological loss of motoneurones from the spinal cord causes the remaining axons within a muscle to sprout and to reinnervate the denervated muscle fibres. Sprouting occurs at two sites along intramuscular axons, at nodes of Ranvier (nodal sprouting) and at the neuromuscular junction (terminal sprouting)[1,2]. Terminal sprouting is also produced by treatment with botulinum toxin and by other agents that render muscle inactive[3–7]. The muscle probably provides a signal for terminal sprouting as restoration of muscle activity by direct electrical stimulation prevents sprouting[8–10]. Such a signal might be a local change on the muscle fibre surface or a 'soluble' sprouting factor[2,4], although the failure to induce terminal sprouting in one muscle by denervating adjacent muscles argues against the latter hypothesis[11–13]. I now report that rabbit antisera against a 56,000 (56K)-molecular weight protein secreted by denervated rat muscle suppress botulinum toxin-induced terminal sprouting in the mouse gluteus muscle. An immune response against this protein has also been detected in serum of patients with amyotrophic lateral sclerosis (ALS), a disease in which loss of motoneurones from the spinal cord is not accompanied by the degree of sprouting and reinnervation seen in other motoneurone diseases[14].

In 1977, Lømo, Brockes and Raff produced a rabbit antiserum against dialysed medium conditioned by an organ-cultured rat hemidiaphragm that was freshly denervated by being placed in culture. An IgG fraction from the antiserum thus obtained was used to construct an immunoaffinity column over which was passed medium conditioned (DdiaCM) by a hemidiaphragm that had been denervated 4 days *in vivo* before being placed in culture. The material that passed through the column was used to produce a second antiserum. In 1981, preliminary results obtained by Kemplay and Stolkin suggested that the second antiserum suppressed partial denervation-induced terminal sprouting in the rat sternocostalis muscle by about one-half (personal communication). I obtained a similar effect using the rat fourth deep lumbrical muscle (denervation protocol as in ref. 5). None of the first antiserum remained for testing.

To produce a second blocking antiserum, I fractionated the DdiaCM protein by gel filtration and took two size fractions for immunization (see Fig. 2 legend). Material eluting in the void volume of the column was used to immunize two rabbits (D5 and D6), and material eluting at ~60–40K was used to immunize a second pair (D7 and D9). These molecular weight ranges were chosen on the basis of preliminary immunoblot analysis of the antigens in the DdiaCM reacting with the blocking antiserum produced by Lømo, Brockes and Raff. A fifth rabbit (D8) was immunized with the unfractionated DdiaCM. The five antisera were tested for suppression of botulinum toxin-induced terminal sprouting in the mouse gluteus muscle (see Fig. 1 legend). Only antisera from D7 and D9 significantly suppressed sprouting (by 60% and 40%, respectively; see Table 1). D7 antiserum also suppressed terminal sprouting in C5-deficient, DBA/2NCox mice (Laboratory Supply Co.), but failed to suppress sprouting if delivered intraperitoneally (i.p.) rather than subcutaneously (s.c.) over the surface of the gluteus. Immunoblot analysis of the antigens in the DdiaCM reacting with the various antisera revealed that an antigen of molecular weight ~56K reacted with the D7 and D9 antisera, but not with any of the non-blocking antisera (Fig. 2). The antigen was a minor component of the DdiaCM which was not visualized in Coomassie blue-stained gels. To purify this antigen for immunization, 1 mg of

Table 1 Effects of antisera on botulinum toxin-induced terminal sprouting in the mouse gluteus

Serum	Toxin	SP%	NSP%	P (SP%)	P (NSP%)
D6pre	0712	55 ± 5	101 ± 9	NS	NS
D10pre	0911	42 ± 9	84 ± 18	NS	NS
D8	0712	43 ± 5	79 ± 9	NS	0.05
D5	0630	60 ± 6	105 ± 10	NS	NS
D6	0630	56 ± 7	98 ± 13	NS	NS
D7	0401	17 ± 3	36 ± 6	0.0001	0.0001
D9	0712	33 ± 4	61 ± 8	0.005	0.0005
D10	0910	32 ± 4	68 ± 8	0.005	0.005
D11	0823	28 ± 3	69 ± 7	0.0005	0.005

The data base consisted of the nine groups of eight mice each listed (D6pre and D10pre were pre-immune sera), six groups of mice that received sera from neurologically normal human subjects, six groups that received sera from patients with diabetic peripheral neuropathy and 19 groups that received sera from sporadic ALS patients. The data for the human sera tested are reported in detail elsewhere[20]. One-way analysis of variance (Statistics Package for the Social Sciences[28]) was used to establish that within each control treatment the distribution of SP% (% of axon terminals with sprouts) for the mice within individual groups did not differ (toxin alone, pre-immune rabbit, normal human, diabetic), and that the distribution of mean SP% for the groups within the different control treatments did not differ across the treatments (d.f. 3, 14; $F = 1.189$; $P = 0.35$). Thus, the controls were homogeneous and the data could be pooled. The distribution of SP% for the pooled data (138 muscles) was normal (χ^2 goodness of fit test) with mean 47.9%, σ 16.1%. To assess which sera significantly suppressed sprouting, the z-score for each experimental group was tested against the parameters of the normal distribution for SP% of the pooled controls. During the study, six dilutions of the 10 $\mu g\,ml^{-1}$ toxin stock were used (listed by date in the second column). The SP% averaged among control groups that received each dilution did not differ significantly (F-test), but ranged from 41 to 57%. To remove this source of variation, the mean SP% for each group was normalized against the average SP% for the control groups receiving the same dilution of toxin (NSP%). The parameters of the distribution of NSP% for the pooled controls were mean 100%, σ 33%. The probabilities of the calculated z-scores for SP% and NSP% are given. Values shown are ±s.e. NS, not significant.

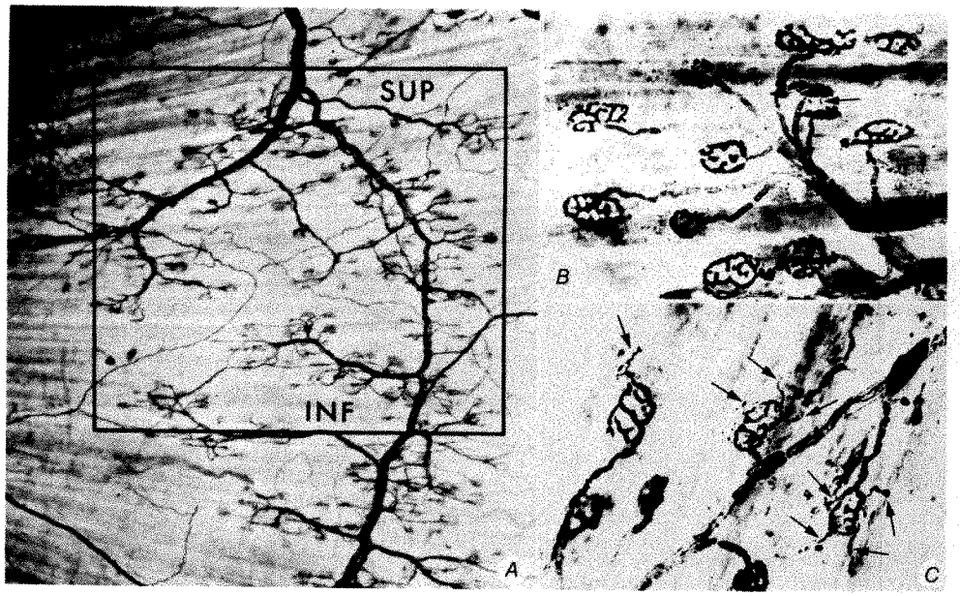

Fig. 1 *A*, Whole mount of the mouse gluteus muscle stained by a combined silver–cholinesterase technique[23] to indicate details of its innervation. The gluteus was chosen for the sprouting assay as both toxin and experimental antisera could be injected directly over the surface of the relatively thin sheet of muscle fibres. Also, the muscle could be viewed in whole mount, which left the terminals undisturbed by the dissection (magnification ~×35). *B*, Zinc iodide–osmium tetroxide-(Z10)-stained nerve terminals in a botulinum-treated muscle exposed to an antiserum (D7) that suppressed terminal sprouting. *C*, Same as *B* but exposed to an antiserum (D8) having no effect. Fine processes are seen sprouting from some of the axon terminals (arrows in *B* and *C*; magnification ~×190). Except for the presence of fewer sprouting terminals in *B* than in *C*, no other histological differences were apparent in the Z10-stained material. The superior (SUP) and inferior (INF) gluteal nerves can be seen to meet across the midsection of the muscle in *A*. In each muscle examined, the SP% (see Table 1) was determined in the zone of innervation of the superior gluteal nerve within the region delimited by the box. An average of 100 terminals was scored for sprouting in each muscle.

Methods: To induce terminal sprouting, female ICR mice (Spraque–Dawley, 20–24 g) were injected s.c. over the surface of the right gluteus muscle with ~250 pg of botulinum toxin type A (Sigma) in 5 μl of 70 mM NaH_2PO_4, 0.2% gelatin buffer (*p*H 6.5). The toxin was diluted from a 10 μg ml^{-1} stock and titred by injecting five groups of eight mice each with 62.5, 125, 250, 500 and 800 pg of toxin, respectively. The index of terminal sprouting (SP%) increased linearly over the 62.5–250 pg doses (from 25 ± 4% to 49 ± 4%). The 500 and 800 pg doses produced 37% and 75% lethality, respectively, while the 250 pg dose chosen for the study produced only 4% lethality overall (512 mice injected). Visible signs of paralysis were flacidity of the ipsilateral abdominal wall and diminution of the toe spreading reflex in the injected leg. On each of the 6 days after toxin injection, groups of eight mice were injected s.c. over the gluteus with 0.1 ml of a heat-inactivated (60 °C, 30 min) test serum. Groups of mice injected with toxin alone, or that received the series of injections with serum, were killed 7 days after toxin injection. The gluteus was excised and stained with Z10[24] for 3 h in the dark at 23 °C. Muscles were cleared in xylene and whole-mounted in Permount. Before microscopic examination (×250 magnification with a Leitz Pl Apo 25/0.65 objective), slides were randomly coded in batches of 40–80 (from 5–10 experimental groups). Data for six muscles that stained too darkly and six that stained too lightly were eliminated from the study before decoding (out of 488 muscles examined); no other selection of the data was made.

protein from the 60–40K AcA-44 fraction was separated on a 7.5% SDS-polyacrylamide gel (see Fig. 2 legend). After brief staining with Coomassie blue to visualize the major proteins in the fraction, the region of ~60–54K was excised from the gel, homogenized in saline, then used to immunize another pair of rabbits (D10 and D11). Antigenic material was recovered from the gel as both rabbits developed antisera that suppressed terminal sprouting (Table 1). Both D10 and D11 antisera reacted with the 56K antigen on immunoblotting, although neither was monospecific (Fig. 2). D11 reacted with some poorly resolved material of 66K and 60K which also reacted with D9, but not with D7 or D10. D10 reacted with some material of ~63K which also reacted with D7, but not with D9 or D11. Thus, the 56K antigen still seeemed the most likely candidate for the antigen of interest. The other material, but not the 56K antigen, was also detected in immunoblots of rat serum reacted with D10 or D11.

Clinical studies have been unable to determine whether the decreased reinnervation seen in ALS is an active process of the disease, or simply due to motoneurone death outpacing the rate of reinnervation[14–19]. Evidence that ALS sera suppressed terminal sprouting would favour the first hypothesis. To test this, serum samples were obtained from 19 sporadic ALS patients with both upper and lower motoneurone signs and tested for suppression of sprouting in the mouse gluteus assay. Sprouting was significantly suppressed by 8/19 ALS sera (NSP%, $P < 0.05$; see Table 1 legend), but not by six sera from healthy individuals[20]. The three most effective sera (N.L., R.V. and E.Z.; NSP%: 9 ± 2% (±s.e.), 47 ± 10%, 71 ± 10%, respectively) were reacted with immunoblots of the rat DdiaCM. Each reacted with the rat 56K antigen and little else in the DdiaCM, while none of the six normal human sera reacted with the antigen (data for N.L. and R.V. are shown in Fig. 2). These data provide evidence for active suppression of sprouting in some cases of ALS. The detection of antibody against the rat 56K antigen in several blocking ALS sera further implies that the disease may have an autoimmune component directed against a human equivalent of the rat antigen, and provides independently derived evidence corroborating the results obtained with the experimental antisera.

Due to the polyclonal nature of the sera used in the study, identification of the 56K antigen as the effective antigen for eliciting a blocking antiserum has not been unequivocally established—that will require the use of a monoclonal reagent, which is now being produced. Nor can the biological role of the 56K antigen be defined with the data in hand. However, the molecular weight of the antigen on gel filtration (60–40K) and on SDS-polyacrylamide gel electrophoresis (SDS-PAGE) is similar to that reported for activities in conditioned medium that stimulate neurite outgrowth from spinal cord explants[21] and dissociated spinal cord neurones[22]. Preliminary experiments have shown that the 56K antigen co-purifies 100–200-fold with an activity(s) that promotes sprouting of neurites and enhances survival of dissociated spinal cord cells in culture, but elucidation of the antigen's biological activity awaits its final purification.

I acknowledge the support of the MRC Neuroimmunology Project (University College, London) where preliminary studies were completed; and thank M. Raff, J. Brockes and T. Lømo for their gift of the initial antiserum used in the study; S. Kemplay and C. Stolkin for sharing their preliminary results; M. Brown, W. Hopkins, S. Bevan, M. Duxson, J. Winter, D. Lawson and G. Rougon for advice; A. Belton for her assistance; J. Antel and N. Cashman for providing the ALS sera; and P. Grobstein, D. Van Essen and K. Drickamer for reading the manuscript.

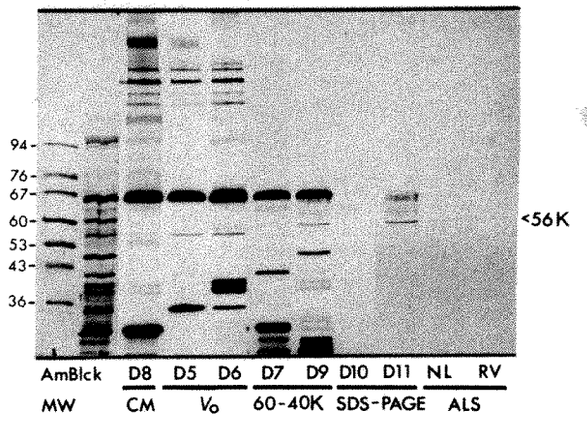

Fig. 2 Immunoblot analysis of the sera described in the text. Molecular weight markers were loaded in the lane marked MW and the other lanes were loaded with 35 μg of protein obtained from medium conditioned by a denervated rat hemidiaphragm (DdiaCM). The first two lanes of the filter were stained for protein with amido-black, the rest were allowed to react individually with one of the sera described in the text. Bound γ-globulin was detected with ^{125}I-labelled *Staphylococcus* protein A and the autoradiogram of the filter is shown. The antisera produced in rabbits D8, D5 and D6 failed to suppress terminal sprouting, while those from D7, D9, D10 and D11 all exhibited suppression. Sera from two ALS patients (N.L. and R.V.) also suppressed terminal sprouting. All sera that suppressed terminal sprouting reacted with an antigen of ~56K (56.6 ± 0.5K, ±s.d. for three determinations) which is believed to be the effective antigen in the immunizations.

Methods: The left hemidiaphragms of male Sprague–Dawley rats (150–200 g) were denervated by cutting the phrenic nerve under ether anaesthesia, and cultures were prepared as described by Merlie *et al.*[25], except that no serum was added to the medium. The medium consisted of Dulbecco's modified Eagle's medium (Flow Labs) supplemented with 33 μg ml^{-1} bovine insulin (Sigma) and 35 μg ml^{-1} *p*-aminobenzoic acid with buffering maintained by bicarbonate in an atmosphere of 5% CO_2 in O_2 at 37 °C. The hemidiaphragms were pinned out on Sylgard (Dow Corning) slants poured in 100-mm Petri dishes and were rocked twice per min. After 2–4 h in culture, the medium was replaced, then collected after a further 24 h (DdiaCM). Protein content ranged from 1 to 2 mg ml^{-1} (Bio-Rad protein assay; horse γ-globulin protein standard). The DdiaCM was stored frozen at −20 °C for up to 6 months. Antisera were produced in female SPF New Zealand White rabbits (12–14 kg). D8 antiserum was raised against the dialysed (50 mM NaH_2PO_4, 1 mM Na_2EDTA, *p*H 7.5, 4 °C), unfractionated DdiaCM. To fractionate the DdiaCM by gel filtration for immunization of D5, D6, D7 and D9, 100 ml of DdiaCM (45 mg protein) were dialysed against 0.1 M NaH_2PO_4, 0.2 M NaCl, 5 mM Na_2EDTA (*p*H 7.5) at 4 °C, concentrated by ultrafiltration to 6 ml (Amicon stirred cell, YM-10 membrane), then applied to a 2.5 × 100 cm column packed with AcA-44 (LKB) and eluted in the same buffer at a flow rate of 17.5 ml hr^{-1}; 8-ml fractions were collected. The column was calibrated with thyroglobulin to indicate the void volume (V_0), bovine serum albumin (67K), ovalbumin (44K), and carbonic anhydrase (29K). Fractions containing material that eluted in the V_0 (15.6 mg protein) were pooled as were fractions eluting between 60 and 40K (6.3 mg protein). The two pooled fractions were dialysed against 20 mM ammonium bicarbonate, then lyophilized. Rabbits D5 and D6 were immunized with the V_0 AcA-44 fraction, while D7 and D9 received the 60–40K AcA-44 fraction. For immunization, 1 mg of protein (dry weight) was dissolved in phosphate-buffered saline (PBS; 5 mM NaH_2PO_4, 0.9% NaCl, *p*H 7.5) and emulsified in an equal volume of adjuvant. Freund's complete adjuvant was used for the first immunization (10–15 intradermal sites) and in a second immunization at 2 weeks. After 6 weeks, booster injections were given in incomplete adjuvant; blood was obtained two weeks after each boost. After collection, blood was clotted, the serum separated, heat-inactivated at 60 °C for 30 min, then stored frozen at −20 °C in 1-ml aliquots for use in the sprouting assay. To purify antigen by preparative SDS-PAGE for the D10 and D11 immunizations, 1 mg of the lyophilized 60–40K AcA-44 fraction was boiled for 2 min in 10% (w/v) glycerol, 0.08 M Tris-HCl *p*H 6.8, 2.0% (w/v) SDS, 5.0% (v/v) β-mercaptoethanol and electrophoresed through a 1.5 mm-thick, 7.5% SDS-polyacrylamide gel[26]. The gel was briefly stained in Coomassie blue (0.125% in 10% acetic acid, 50% methanol) then destained in 10% acetic acid, 15% methanol. The 60–40K AcA-44 fraction contained the prominent doublet at ~60K seen in the DdiaCM stained with amido-black, as well as the next prominent band of ~54K. The region between these two markers was cut from the gel, briefly rinsed in several changes of PBS, minced, then Dounce-homogenized in 1–2 ml of PBS. The gel slurry was emulsified in Freund's complete adjuvant for the first immunization, then in incomplete adjuvant for immunizations at 10 and 13 weeks. D10 was exsanguinated at 17 weeks. D11 was bled at 15 weeks, at which time it exhibited muscle wasting and had lost about one-third of its body weight; this rabbit died 1 week later and the carcass was unintentionally destroyed. All of the other rabbits remained healthy and a muscle biopsy of D7 at 10 weeks showed no signs of denervation (K. Stefansson, data not shown). For immunoblotting, 35 μg of DdiaCM protein in culture medium was boiled in the above SDS sample buffer and electrophoresed through a 1.5 mm-thick, 7.5% polyacrylamide (bis, 2.5% w/w of total monomer) slab gel[26] with cooling. The protein was electrophoretically transferred[27] from the gel to a nitrocellulose filter (BA85; Schleicher and Schuell) at 3.5 V cm^{-1}, 0.2 A for 1 h. After transfer, staining of the trichloroacetic acid-fixed gel with Coomasie blue demonstrated complete transfer of all protein having a molecular weight <94K. Individual lanes were cut from the filter and stained for protein with amido-black (0.1% in 10% acetic acid, 50% methanol) or soaked in 5% haemoglobin in PBS–NaN_3 for 1 h to block reactive sites. The 'blocked' strips were reacted overnight at 23 °C with sera diluted 1:50 in 1% haemoglobin. IgG bound to the filter was detected by incubation for 3 h with *Staphylococcus* protein A (Sigma) iodinated by the chloramine-T method to 5–10 μCi per μg protein, followed by exposure to Kodak XRP-5 film overnight at 4 °C. Molecular weight markers (Sigma) were: phosphorylase B (94K), human transferrin (76K), bovine serum albumin (67K), catalase (60K), glutamic dehydrogenase (53K), ovalbumin (43K) and lactate dehydrogenase (36K).

The work was supported in part by NIH HD05940 and by the Searle Scholars Program.

The human retina is unmyelinated, but structural similarities have been noted between Müller cells, the main glial cell type of retina, and oligodendrocytes, the myelin-forming cells of the central nervous system[1]. We now show that antibodies against myelin-associated glycoprotein, a minor component of central and peripheral myelin so far found only in myelin and myelin-forming cells[2–4], also stain Müller cells. Immunoblot analysis of retinal proteins indicates that the antigen detected is myelin associated glycoprotein. These results suggest a closer relationship between Müller cells and oligodendrocytes than previously suspected and raise questions about the functional role of myelin-associated glycoprotein.

Rat monoclonal antibodies against myelin-associated glycoprotein were obtained as a by-product of attempts to raise monoclonal antibodies specific for membrane-bound nicotinic acetylcholine receptor (AChR) from the electric organ of *Torpedo californica*. Rats were immunized with AChR from the electric organ, tissue known to be rich in myelinated axons. The preparation of acetylcholine receptor used for the immunization was later shown to be contaminated with myelin. The monoclonal antibodies were raised by fusing spleen cells from the immunized animals to the non-secreting mouse myeloma cell line SP2/O-Ag14 using the hybridoma technique of Köhler and Milstein[5], slightly modified[6]. The hybridoma supernatants were screened against AChR-containing membrane preparations from the electric organ using an enzyme-linked immunoassay[7]. Two IgG monoclonal antibodies produced in this way ($BRIC_{37}$ and $BRIC_{38}$) that did not bind to the acetylcholine receptor reacted on a Western blot[8] with isolated human MAG (given by Dr R. H. Quarles). When Western blots of homogenates of adult human spinal cord or human peripheral nerves were studied, the antibodies reacted only with bands having relative mobilities identical to that of MAG (Fig. 1). The monoclonal antibodies showed no reaction with Western blots of homogenates from human liver, kidney or striated muscle.

The immunohistochemical distribution of the antigen with which $BRIC_{37}$ and $BRIC_{38}$ react is identical to that described for MAG[3,4]. The antigen is present in myelin sheaths of the central and peripheral nervous systems as well as in the cytoplasm of oligodendrocytes just prior to and during myelination. As controls for $BRIC_{37}$ and $BRIC_{38}$, both on the Western blots and in immunohistochemical work, we used several monoclonal antibodies against the nicotinic AChR[6]. We also used serum from a patient (M) with IgM monoclonal gammopathy and neuropathy whose monoclonal IgM is directed against human MAG[9] (Fig. 1). As controls for this serum we used sera from several patients with IgM monoclonal gammopathy unaccompanied by neuropathy. It has been demonstrated by peptide mapping that $BRIC_{37}$ and $BRIC_{38}$ may react with the same epitope on MAG but one which differs from that which reacts with IgM from the patient's (M) serum (L.S.M. and K.S., in preparation).

Sections of formalin-fixed, paraffin-embedded human retinas obtained from autopsy and surgical material were stained immunohistochemically with $BRIC_{37}$ and $BRIC_{38}$ using the peroxidase–antiperoxidase (PAP) method of Sternberger[10]. They were also stained with the patient's serum described above, using the biotin–avidin peroxidase technique[11]. There was intense staining of processes throughout the retina, reaching down to the inner limiting membrane and up to the outer limiting membrane (Fig. 2). At the outer limiting membrane there was staining of the fine processes of the Müller cells that reach between the inner segments of the photoreceptors. A few nuclei in the inner nuclear layer were outlined by a darkly staining rim (Fig. 3). These nuclei were located where nuclei of Müller cells are known to be present. This staining pattern is similar to that described for monoclonal antibodies raised against Müller cells[12]. The controls gave no staining (Fig. 2).

Fresh normal human retinas were homogenized, solubilized, electrophoresed on a polyacrylamide gel, and blotted onto nitrocellulose paper as described previously[9]. The nitrocellulose paper was subsequently exposed to $BRIC_{37}$, $BRIC_{38}$ or the patient's (M) serum. The anti-MAG antibodies identified a band having a relative mobility identical to that of MAG (molecular weight (M_r) ~ 100,000), another band of ~130,000 M_r, a third at ~200,000 M_r and a few minor bands of larger molecular weights (Fig. 1). The controls identified nothing on the blots. It has been shown previously that MAG from developing rats and myelin-deficient *quaking* mice has a molecular weight larger (but only by 10,000 to 25,000) than MAG isolated from normal adult animals (refs 13, 14). Therefore, we examined the molecular weights of proteins with which the anti-MAG antibodies react in the developing human central nervous system (CNS) and in the brain stem: for example, at 31 weeks of gestation the antibodies react with only two pairs of bands, one of M_r >250,000, the other of M_r ~200,000. At 37 weeks of gestation the anti-MAG antibodies react with three bands: one of M_r ~225,000, another of ~200,000 and the third one ~100,000. At 7 months postnatal the anti-MAG antibodies react only with an antigen having a molecular weight of 100,000 (L.S.M. and K.S., in preparation). It seems, therefore, that the 'immature' MAG in the human CNS is larger than that in rodents. All the bands identified by the anti-MAG antibodies in the human retina, including the 130,000-M_r protein, are

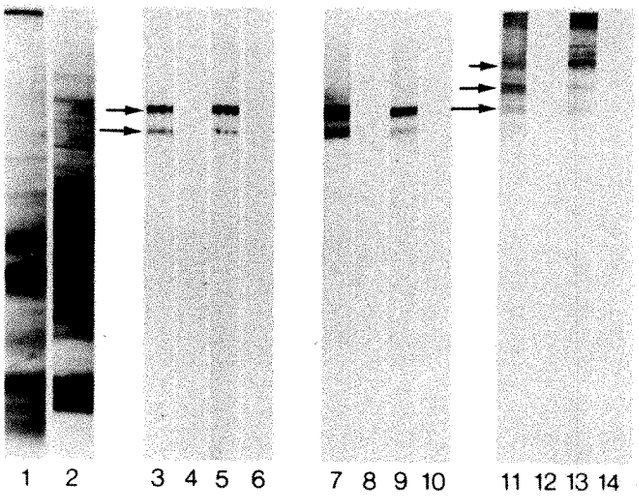

Fig. 1 Western blots of isolated MAG (lanes 3–6), homogenate of adult human spinal cord (lanes 7–10) and homogenate of human retina lanes (11–14). The isolated MAG, the spinal cord homogenate and the retinal homogenate were run side by side on a 3-well SDS-polyacrylamide gel using the Fairbanks system[19] (lane 1 is a Coomassie blue-stained gel of the spinal cord homogenate and lane 2 is the same for retinal homogenate). The antigens were subsequently transferred electrically to nitrocellulose sheets. The nitrocellulose sheet was then cut into strips and the rest of the staining procedure was carried out with each of the strips in a capped test tube (for experimental details see ref. 9). Next, gel lanes 3, 7 and 11 were incubated with $BRIC_{37}$; 4, 8 and 12 with control monoclonal antibody; 5, 9 and 13 were incubated with the patient's (M) serum; and 6, 10 and 14 with a control serum from a patient with IgM monoclonal gammopathy without accompanying neuropathy. Then strips 3, 4, 7, 8, 11 and 12 were incubated with peroxidase-labelled rabbit anti-rat immunoglobulins and strips 5, 6, 9, 10, 13 and 14 were incubated with peroxidase-labelled rabbit anti-human IgM. The bound immunoglobulins were revealed by dipping the strips into diaminobenzidine–H_2O_2 solution. $BRIC_{37}$ (lane 3) and IgM from the patient's serum (lane 5) bound to isolated MAG (short arrow) and dMAG (long arrow) (dMAG is a degradation product of MAG[20]) and only to MAG and dMAG in the spinal cord homogenate (lanes 7 and 9). In the retinal homogenate both $BRIC_{37}$ (lane 11) and IgM from the patient's (M) serum (lane 13) identified three major bands: one with a relative mobility identical to MAG (longest arrow), another with a M_r ~ 130,000 (middle arrow) and the third with a M_r of ~200,000 (shortest arrow). The control monoclonal antibody (lanes 4, 8, 12) and the control serum (lanes 6, 10, 14) were totally negative. There are some differences between $BRIC_{37}$ and IgM from the patient's (M) serum with respect to relative intensity of the bands. $BRIC_{37}$, for example, stains dMAG in the spinal cord homogenate (lane 7) more intensely than does IgM from the patient's serum (lane 9). $BRIC_{37}$ also brings out dMAG in the retinal homogenate (11) whereas IgM from the patient's (M) serum does not (13). However, IgM from the patient's (M) serum stains the 200,000-M_r protein in the retinal homogenate (13) more darkly than does $BRIC_{37}$ (11). These differences are probably a reflection of the fact that $BRIC_{37}$ and the IgM from the patient's (M) serum do not react with the same epitopes on MAG. $BRIC_{38}$, which appears to bind to the same epitope as $BRIC_{37}$, gives the same relative intensities of bands on blots of retina and spinal cord as does $BRIC_{37}$.

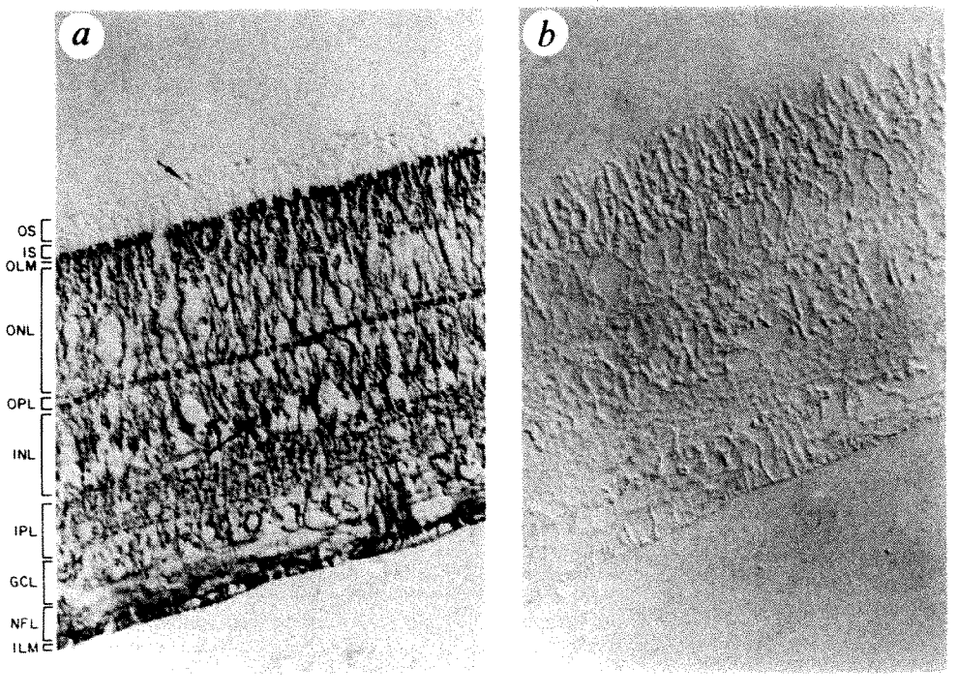

Fig. 2 *a*, Section of formalin-fixed, paraffin-embedded human retina stained with $BRIC_{37}$ (PAP technique). The photograph is taken through differential interference optics (Nomarski), ×400 before photographic conversion. There is intense staining of processes throughout the retina. The long arrow points to the location of nuclei of Müller cells, the short arrow to unstained photoreceptors. OS, outer segment of photoreceptors; IS, inner segment of photoreceptors; OLM, outer limiting membrane; ONL, outer nuclear layer; OPL, outer plexiform layer; INL, inner nuclear layer; IPL, inner plexiform layer; GCL, ganglion cell layer; NFL, nerve fibre layer; ILM, inner limiting membrane. *b*, A section from the same block as that shown in *a*, stained with one of the controls and photographed in the same manner as *a*.

identified in the human CNS at one time point or another during development. Thus, it appears that the antigens in the retina with which the anti-MAG antibodies react may be a mixture of the 'immature' and 'mature' forms of MAG.

The normal human retina is unmyelinated throughout life[1] yet the retina is the only site at which MAG has been found outside the myelin sheath and myelin-forming cells—this observation underlines the need to look beyond myelination in the search for a functional role for MAG. It is also of interest that in the retina MAG appears to be present in Müller cells. Barnstable[12] has described a monoclonal antibody which in the rat retina reacts only with Müller cells and also binds to astrocytes in all regions of the brain. There are several other features that astrocytes and Müller cells have in common, such as close apposition to neuronal processes[15], potassium ion transport[16] and γ-aminobutyric acid transport[17]. However, it has been demonstrated that in the nerve fibre layer of chicken retina, Müller cells form a myelin-like sheath around thick axons[18]. Therefore it could be argued that they bear some resemblance to oligodendrocytes and Schwann cells. The presence of MAG on human Müller cells adds a new feature to that resemblance and provides another reason for considering the possibility that the Müller cells may be more than simply specialized retinal astrocytes.

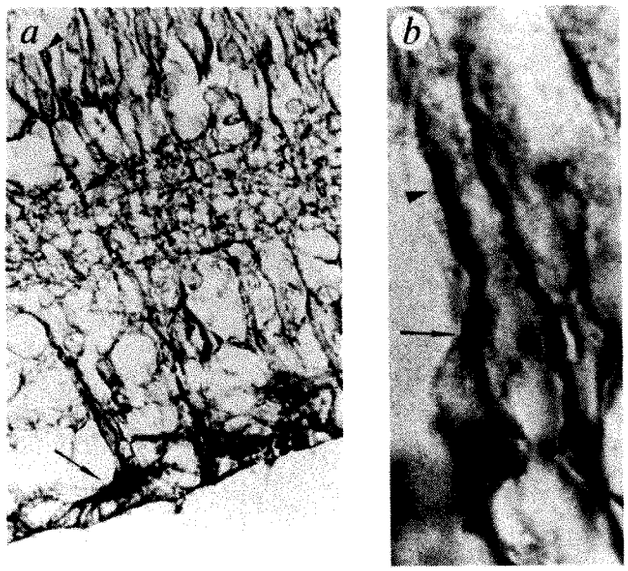

Fig. 3 *a*, Section of paraffin-embedded human retina stained with $BRIC_{37}$ (PAP technique). The long arrow points to the footplate of a Müller cell; the arrowhead to a perinuclear area of a Müller cell which is shown at higher magnification in *b*. A process from this cell can be followed all the way to the inner limiting membrane (thick arrow) (Nomarski ×300). *b*, The perikaryal area of a Müller cell (arrow) and a characteristically broad ascending process (arrowhead). Only the plasma membrane is stained. There is no staining of the nucleus or the cytoplasm (Nomarski ×1,200, oil immersion).

Modulation of the response of a photosensitive muscle by β-adrenergic regulation of cyclic AMP levels

L. J. Rubin

Department of Anatomy, University of Colorado Health Sciences Center, Denver, Colorado 80262, USA

The light-induced constriction of the irises of some vertebrates is mediated by photosensitive pupillary sphincter cells, which have rhodopsin molecules in their sarcolemmas[1–6]. Light-induced isomerization of these rhodopsin molecules leads to the relase of Ca^{2+} from an internal pool, which in turn activate the contractile proteins[2,4,7]. A central nervous reflex is therefore not essential for the light responsiveness of these irises, but they do appear to be innervated[8–14]. The photosensitive iris of the toad receives sympathetic (adrenergic) innervation. Stimulation of sympathetic nerves to the eye[11] or application of adrenergic agonists to the iris[8,14] cause pupillary dilation due to relaxation of the sphincter muscle. We show here that β-adrenergic stimulation of toad sphincter cells modulates their photoresponses by elevating the intracellular levels of cyclic AMP. However, cyclic AMP does not appear to be involved in the transduction event but rather alters the availability of Ca^{2+} for contraction.

Irises of the toad *Bufo marinus* were isolated by opening the eye cup posteriorly and removing the lens and sclera, except for a small circumferential stric of sclera attached to the iris. This scleral strip was pinned with the anterior iridial surface upwards to a clear silicone rubber substrate in a perfusion chamber and placed in an IR pupillometer[13]. The output of the pupillometer was calibrated as pupillary area (mm^2) and provided continuous monitoring of iridial strip responses to both light and drug treatment. The scleral strip and attached iris were pinned so as to avoid any external tension on the sphincter muscle. The toad iris does possess a dilator muscle (contrary to the results of Armstrong and Bell[8]) but it is unresponsive to either light or adrenergic stimulation[15].

Addition of adrenergic agonists to irises causes a pronounced pupillary dilation and variable changes in the size of light responses. This response is elicited most easily by the β-adrenergic agonist isoprenalin and least easily by the α-agonist phenylephrine, suggesting that the effect of adrenergic stimulation is mediated by β-adrenergic receptors. This is supported by the observation: (1) the effect of isoprenaline, adrenalin or phenylephrine is blocked by the β-antagonist propranolol (Fig. 1), but not by the α-antagonists phentolamine or phenoxybenzamine; (2) the response is elicited by a 1,000-fold lower concentration of isoprenaline than phenylephrine; and (3) propranolol antagonizes the pupillary response elicited by high-potassium depolarization and subsequent release of endogenous neurotransmitter[15]. Low concentrations of isoprenaline (10^{-9}–10^{-8} M) always cause pupillary dilation of dark-adapted, previously untreated irises ($n = 23$). However, the sensitivity of the light response to isoprenaline treatment varies slightly between animals. Low concentrations of isoprenaline affect light responses by either increasing ($n = 16$) or decreasing ($n = 7$) the peak-to-peak amplitude of responses. In cases where isoprenaline causes an increase in the amplitude of light responses, higher concentrations of isoprenaline (5–10 times) cause a decrease in response amplitude. However, in most cases the decrease of response amplitude caused by isoprenaline is transient (Fig. 2). One possible explanation is that the β-adrenergic receptors desensitize rapidly. However, since this effect is not transient (up to 1 h) if a cyclic AMP-phosphodiesterase (PDE) inhibitor is also present, a more likely explanation is an increase in PDE activity and subsequent reduction of cyclic AMP levels.

The toad iris appears to resemble other systems in that β-adrenergic receptors affect cells by activating adenylate cyclase

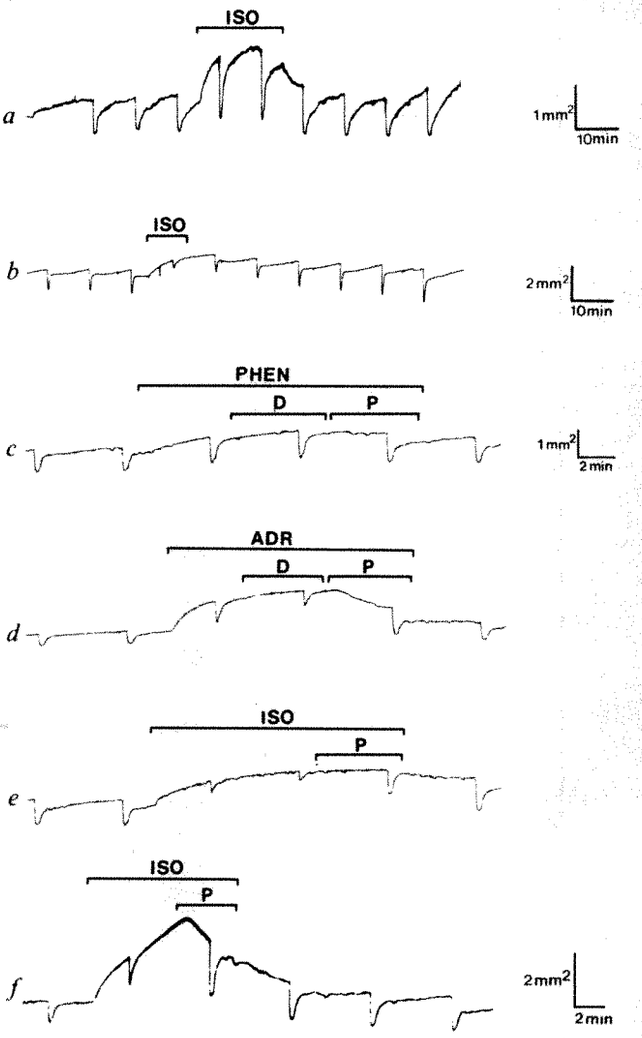

Fig. 1 Tracings of the output of the pupillometer (pupillary area). Stimulation with light causes a downward deflection of the tracing and indicates a decrease in pupillary area equivalent to pupillary constriction. Effect of the adrenergic agonist isoprenaline on pupillary size and light response in four different irises. *a*, *b*, Addition of isoprenaline (ISO, 10^{-8} M) caused pupillary dilation in both cases. However, in one case isoprenaline increased the peak-to-peak amplitude of light responses (*a*) and in the other case it decreased the amplitude of light responses (*b*). *c*–*e*, Tracings from the same preparation. The iris dilates in response to addition of phenylephrine (PHEN, 10^{-6} M), adrenaline (ADR, 10^{-6} M) or isoprenaline (ISO, 10^{-7} M) to the perfusate. Effect of phenylephrine and adrenaline is not blocked by the α-blocker phenoxybenzamine (D, 10^{-6} M) but is reversed by the β-antagonist, propranolol (P, 10^{-6} M), although the reversing effect on phenylephrine response in this iris is slower. Propranolol (P, 10^{-6} M) blocks the effect of isoprenaline (10^{-7} M) on light responses but does not rapidly return the dark-adapted iris to pretreated levels of dilation. Concentrations of propranolol 100 times the isoprenaline concentration do block and reverse the effect of isoprenaline (*f*). All drug solutions are prepared fresh from frozen stock solutions (10^{-3} M dissolved in 2–5 mM HEPES Ringer's, *p*H 4.8). Stock solutions of agonists are supplemented with ascorbic acid (50 mg l^{-1}) to retard oxidative degradation[29]. Perfusion rate was one to four times the chamber volume per min. Light stimulus intensity was 16.45 mW cm^{-2}.

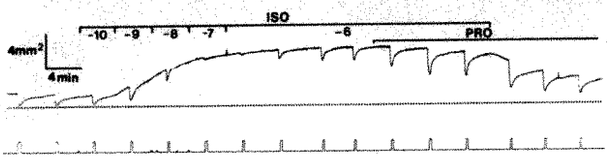

Fig. 2 Effect of progressively higher doses (log concentrations) of isoprenaline (ISO) on pupillary responses to light. Lower trace is the output of a light monitor. Dotted line is an arbitrary reference line. Low concentrations of isoprenaline (10^{-9} M) cause pupillary dilation and slightly increase the amplitude of the light response. To decrease the amplitude of light responses the concentration of isoprenaline was increased successively. High concentrations of isoprenaline (10^{-6} M) still only transiently reduce the size of light responses. Addition of propranolol (PRO, 10^{-6} M) to an isoprenaline-treated iris partially antagonizes the effect of isoprenaline.

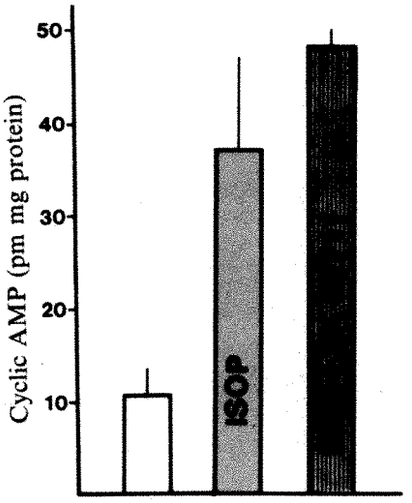

Fig. 3 Cyclic AMP levels of dark-adapted toad sphincters. The irises of 24 toads (*Bufo marinus*) were dissected in dim room light, pinned to a clear silicone rubber base in a Petri dish and then dark-adapted for 15–20 min while maintained in Ringer's solution. Because of the relatively small amount of tissue available for these measurements the largest toads (usually female) were used. In addition, each measurement was made from a pooled sample of four irises from four different animals, thus minimizing individual animal variations. Values represent the mean and standard deviation of the mean of untreated ($n=6$), isoprenaline-treated (ISOP, $n=3$, 10^{-7} M) and ZK62711 with isoprenaline-treated ($n=3$, 10^{-6} M) sphincters. After dark-adaptation the sphincter region was dissected from the remainder of the iris using IR viewers (FJW, Find-R-Scope) mounted on a dissection microscope. For drug treatment, tissue was then immersed in Ringer's solution with drug for 30–60 s and then frozen in liquid Freon at liquid nitrogen temperature. Untreated tissue was placed in fresh Ringer's for 30–60 s and then frozen. Frozen samples were homogenized in cold 5% trichloroacetic acid, centrifuged and the cyclic nucleotide content of the supernatant was determined according to the radioimmunoassay technique of Harper and Brooker[17]. The protein precipitate was processed according to the method of Lowry *et al.*[30].

and thereby increasing cellular concentrations of cyclic AMP[16]. Measurements of cyclic nucleotide levels by radioimmunoassay[17] indicate that isoprenaline causes a fourfold increase in cyclic AMP levels (Fig. 3). Therefore, the pupillary dilation and decrease in the size of light responses observed with isoprenaline treatment may be due to an increase in cyclic AMP levels. This is supported by the enhancement of the effect of isoprenaline on light responses by other agents which increase cyclic AMP levels. Treating irises with PDE inhibitors such as isobutyl methylxanthine (IBMX, $n=3$) or the cyclic AMP-specific PDE inhibitors ZK62711 ($n=10$, Shering)[18,19] or RO201724 ($n=3$, Hoffman LaRoche)[18–20] but not the cyclic GMP-specific PDE inhibitor MB22948 ($n=5$, May and Baker)[18–21] causes a decrease in the size of light responses

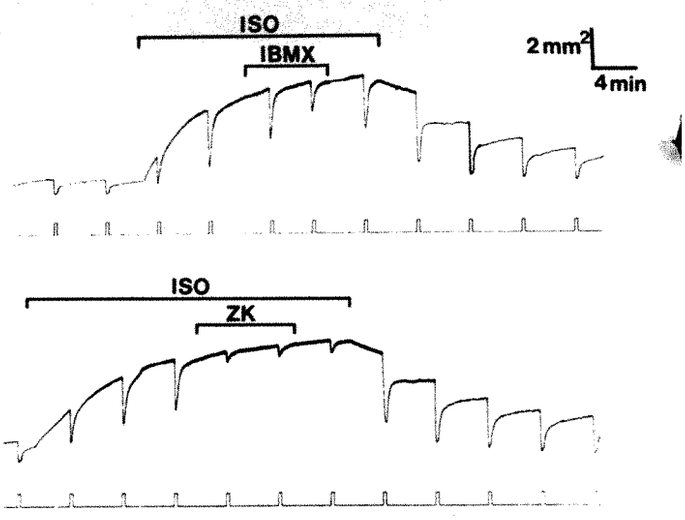

Fig. 4 Potentiating effect of the phosphodiesterase inhibitors ZK62711 and isobutyl methylxanthine (IBMX) on the response of the iris to isoprenaline. Isoprenaline (ISO, 5×10^{-8} M) added to the perfusate bathing the iris caused pupillary dilation and increased the peak-to-peak amplitude of light responses. Treating the iris with IBMX (10^{-5} M) in the presence of isoprenaline reduces the size of light responses. ZK62711 (ZK, 10^{-6} M) in the presence of isoprenaline produced an even greater decrease in light responses which persisted for as long as the inhibitor was present with isoprenaline. ZK62711 alone had no effect on either the dark-adapted iris or on light responses.

beyond that caused by isoprenaline alone (Fig. 4). Irises treated with isoprenaline and ZK62711 contain slightly higher levels of cyclic AMP than irises treated with isoprenaline alone (Fig. 3). In addition, the effect of isoprenaline on light responses is potentiated by cholera toxin ($n=2$). Cholera toxin is known to enter cells and activate adenylate cyclase irreversibly thereby increasing the intracellular concentration of cyclic AMP[22,23]. Potentiation of the effect of isoprenaline on iridial light responses by specific cyclic AMP–PDE inhibitors and by cholera toxin suggests that cyclic AMP is involved in an inhibition of light-induced contractions.

Although cyclic AMP appears to modify the iridial response to light, preliminary results of another study indicate that cyclic nucleotide levels are not regulated by light in this particular photoreceptor. Furthermore, in the absence of stimulation of β-adrenergic receptors, PDE inhibitors have little or no effect on either the size of the dark-adapted iris or on light responses, suggesting that the basal activity levels of the cyclase as well as the PDE are low. Thus it seems unlikely that activation of a PDE[24,25] and subsequent lowering of cyclic nucleotide levels are involved in phototransduction in the sphincter muscle. The most likely explanation is that cyclic AMP exerts its effect on light responses after the initial transduction events.

There are at least two places where cyclic AMP can act to modulate a contractile response in smooth muscle. Cyclic AMP can inhibit the contractile response by initiating the phosphorylation of myosin light-chain kinase, thus preventing the activation of myofilaments[26]. That is, Ca^{2+} released as a result of exposure to light would have no effect on inactivated myoproteins. Cyclic AMP also causes sequestration of Ca^{2+} by the sarcoplasmic reticulum, thereby making fewer Ca^{2+} available for contraction[27]. Either or both of these mechanisms could be responsible for the effects observed in the present case. However, several pieces of evidence suggest that increased sequestration of Ca^{2+} rather than prevention of activation of myofilaments is the primary cause of the decrease in size of light responses. First, irises that are maximally dilated by agents such as isoprenaline still respond to light. This suggests that the myoproteins are functional. Second, normal irises respond to sustained illumination with a prolonged contraction, but isoprenaline-treated irises

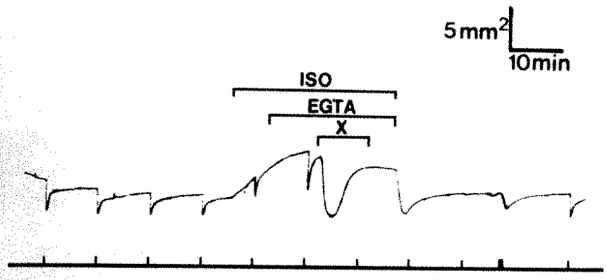

Fig. 5 Effect of calcium ionophore X-537A on the pupillary dilation caused by isoprenaline. In this experiment the iris was treated first with isoprenaline (ISO, 10^{-7} M) in normal Ringer's solution and then by isoprenaline in a low calcium, EGTA (EGTA, 10^{-4} M) solution before addition of the ionophore (X, 5×10^{-6} M) to the same solution. Further experiments indicated that the iris responds to isoprenaline treatment even in the absence of calcium in the perfusate. Therefore, in several experiments the calcium free-EGTA perfusate was started before the application of isoprenaline and ionophore. The results are the same as presented here. The ionophore X-537A causes maximum pupillary constriction and eliminates the response to light.

respond with only a transient contraction, as though Ca^{2+} released by light is rapidly resequestered. Third, the light-induced contraction is larger after either the removal of isoprenaline or the addition of propranolol to an isoprenaline-treated iris. These findings suggest that calcium pools had been loaded during isoprenaline treatment and the stimulus for Ca^{2+} sequestering was then removed.

If the effect of elevated cyclic AMP levels on the sphincter is to increase the sequestering of Ca^{2+} and not affect the contractile proteins directly, then release of Ca^{2+} from these pools should cause a maximum contraction, even in the presence of elevated cyclic AMP levels. This appears to be the case, because perfusion of an isoprenaline-treated iris with the calcium ionophore X-537A[28] in a calcium-free EGTA Ringer's solution causes a rapid maximal pupillary constriction, followed by dilation and complete loss of the light response ($n = 5$, Fig. 5). These results suggest that the myofilaments are capable of contracting during treatment with isoprenaline, but that Ca^{2+} is unavailable due to increased sequestration. The increased size of the light response immediately after some of the treatments with isoprenaline and the temporary absence of light responses after treatment with the ionophore may indicate that at least some of the Ca^{2+} stores augmented by cyclic AMP are sensitive to light.

These results indicate that the autonomous light response of the pupillary sphincter is modified by stimulation of β-adrenergic receptors. Thus, sympathetic innervation of the sphincter appears to regulate at least the amplitude of light responses by regulating the availability of Ca^{2+} for light-induced release. The most likely mechanism for calcium regulation in this system is a cyclic AMP-mediated sequestration of Ca^{2+} into stores; some of these stores are light sensitive. These results also imply that cyclic nucleotides are not directly involved in the transduction process of this muscle.

Complementation in monocyte hybrids revealing genetic heterogeneity in chronic granulomatous disease

Mic N. Hamers, Martin de Boer, Louis J. Meerhof, Ron S. Weening* & Dirk Roos

Central Laboratory of the Netherlands Red Cross Blood Transfusion Service and Laboratory for Experimental and Clinical Immunology, University of Amsterdam, Plesmanlaan 125, 1066 CX Amsterdam, The Netherlands
* Department of Pediatrics, Academic Medical Centre, Meibergdreef 9, 1105 AZ Amsterdam, The Netherlands

Chronic granulomatous disease (CGD) is a rare syndrome, found predominantly in male children and characterized by life-threatening, recurrent infections. The superoxide (O_2^-)/hydrogen peroxide (H_2O_2) generating system in the granulocytes and monocytes of CGD patients is completely defective[1]. Furthermore, a novel type of cytochrome *b*, detected by the optical spectrum of phagocytes from healthy subjects[2,3], is lacking in those of most male CGD patients[4]. In female CGD patients, the cytochrome *b* is present[4], but cannot, as in normal cells[5], be reduced on metabolic stimulation of the phagocytes in anaerobic conditions. Here, to demonstrate the importance of cytochrome *b* in this system and to investigate the genetic background of the various forms of CGD, we have hybridized monocytes from a cytochrome *b* negative, X-linked male CGD patient with monocytes from a cytochrome *b* positive, male CGD patient with unknown genetic background. Monocytes were used because they are the only blood phagocytes that show an active protein synthesis, whereas fibroblasts or lymphocytes do not express the O_2^-/H_2O_2 generating system. The heterologous hybrids were positive in the nitroblue tetrazolium (NBT) slide test, indicating the complementation of the O_2^-/H_2O_2 generating system, whereas the homologous hybrids remained negative, as did the non-fused cells of these patients. We thus conclude that cytochrome *b* is part of the O_2^-/H_2O_2 generating system and that somatic cell hybridization experiments with monocytes provide a means of studying the genetic background of CGD patients. We believe this to be the first report of genetic complementation by somatic cell hybridization experiments using monocytes instead of fibroblasts.

Because two patterns of inheritance of CGD seem to exist—one X-linked[6] and one autosomal recessive[7]—Segal and co-workers[3] have suggested that the absence of cytochrome *b* is correlated with the X-linked form of CGD and that the malfunction of cytochrome *b* is correlated with the autosomal recessive form. However, segregation between the expression of cytochrome *b* and the X-linked form of CGD has recently been described[8]. Moreover, we have discovered three cytochrome *b* negative patients (one male and two females) within one family with the autosomal recessive form of CGD, as well as one cytochrome *b* negative female CGD patient with an unknown genetic background. Table 1 shows the genetic heterogeneity of 12 male and 5 female CGD patients. The CGD families are unrelated to each other in the last four generations. It is clear

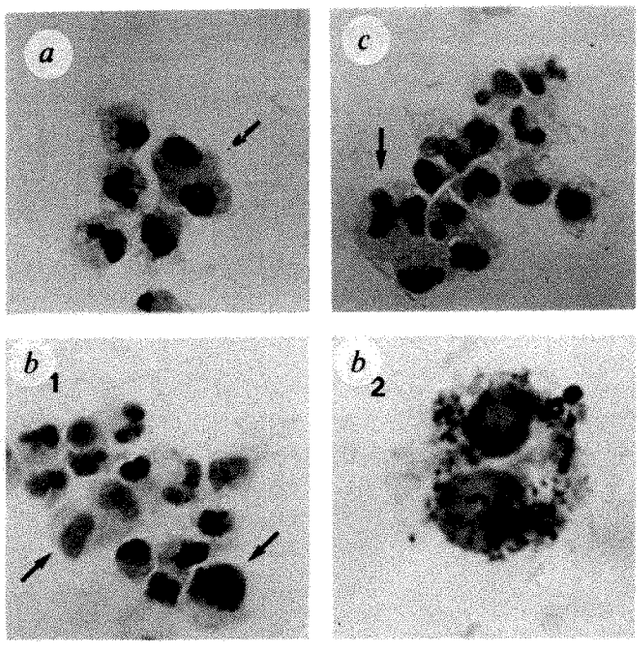

Fig. 1 NBT slide test on somatic cell hybrids of monocytes from two different CGD patients. Patient 1: X-linked, cytochrome *b* negative male; patient 2: cytochrome *b* positive male, mode of disease inheritance unknown. *a*, Fusion product of monocytes from patient 1 (negative in NBT test); b_1, fusion products of monocytes from patient 1 and patient 2 (one negative and one positive in NBT test); b_2, NBT-positive heterologous hybrid (higher magnification); *c*, fusion product of monocytes from patient 2 (negative in NBT test).

Methods: Monocytes (90–95% monocytes, 5–10% lymphocytes, 0–2% basophils) were isolated from mononuclear leukocytes by elutriation[16], 3×10^7 cells were fused with polyethylene glycol (58%, molecular weight 4,000) for 1 min in Dulbecco medium[17] and kept in maintenance culture in round-bottom wells of a microtitre plate in Iscove's modified medium with 10% fetal calf serum. Cells were collected at the indicated times and resuspended in medium of *p*H 7.4 containing 138 mM NaCl, 2.9 mM KCl, 8.1 mM Na_2HPO_4, 1.5 mM KH_2PO_4, 0.6 mM $CaCl_2$, 1.0 mM $MgCl_2$, 5.5 mM glucose and 0.5% (w/v) human albumin. Nitroblue tetrazolium (Sigma) was added at 0.5 mg ml^{-1}, and the cells were stimulated for 30 min with 100 ng ml^{-1} phorbol myristate acetate (Consolidated Midland Corporation). Thereafter, the cells were fixed in suspension with paraformaldehyde (1% v/v), spun onto a glass slide with a Shandon-Elliot Cytospin centrifuge (10 min at 600 r.p.m.), and stained with nuclear fast red (Merck Darmstadt) for 20 min for counting of the NBT-positive hybrids. Part of the unstimulated cells were stained with May-Grünwald (5 min) Giemsa (1 h) to count the total number of monocyte hybrids.

from Table 1 that considerable heterogeneity exists in CGD: 5 of the 12 male patients do not show the X-linked inheritance (compared with 4 out of 20 patients in ref. 4) and 3 (two sibs) of the 5 female patients were cytochrome *b* negative (compared with 2 cousins with partial cytochrome *b* deficiency out of 7 female patients in ref. 3). Furthermore, the discovery of the family with the autosomal recessive trait and absence of cytochrome *b* in their neutrophils, as well as the X-linked CGD patient with cytochrome *b* in this study and the one reported recently[8], preclude correlation between the absence of cytochrome *b* and the X-linked form of CGD. However, the correlation between the absence of cytochrome *b* and CGD in general still holds. The one male patient without cytochrome *b* in 'unknown' category (Table 1) is comparable with the three male patients in ref. 3 without any affected relatives. Because the disease is often fatal in early childhood, a high incidence of spontaneous mutations in the X-linked form may be expected. This might explain why some male patients without cytochrome *b* have mothers and sisters without any sign of heterozygosity. The one female patient without cytochrome *b* in the 'unknown' category is more difficult to explain. She might belong to the autosomal recessive form of CGD without cytochrome *b*, or to the X-linked form of CGD. In the latter instance, she would be heterozygous, with an extreme lyonization pattern (as yet undetected), while her mother would be heterozygous with an extreme lyonization pattern in the opposite way.

Whatever the mode of inheritance in these patients, Table 1 clearly shows that the expression of the O_2^-/H_2O_2 generating system is controlled by at least three genetic loci, one or more of which is located on the short arm of the X chromosome[9,10].

As long as the molecular defects remain unknown, the only way to study the genetic background of the various CGD patients is by complementation analysis of somatic cell hybrids. Generally, fibroblasts are used for this purpose; however, these cells do not express the O_2^-/H_2O_2 generating system, as measured with the NBT reduction test (ref. 11, confirmed by us). Lymphocytes have also been reported to express the O_2^-/H_2O_2 generating system[12], but these cells, too, failed to reduce NBT in our hands (unpublished). The only way to circumvent this problem is to perform complementation studies with bone marrow cells or monocytes, because these cells display an active protein synthesis. For obvious reasons, the use of bone marrow cells is excluded, leaving the possibility of monocytes. However, this implies that very few hybridization experiments can be performed, because for one experiment 100 ml of fresh blood from two patients are required. Cryopreserved monocytes cannot be used, because in control experiments we found that the latter cells yielded somatic hybrids that quickly deteriorate in culture.

The large blood sample is needed for the following reasons: (1) the fusion efficiency of monocytes is 0.4–1%, and at least 2×10^7 monocytes per fusion are required for a good recovery of viable hybrids; (2) the monocytes must be highly purified (>90%) to avoid fusion between monocytes and contaminating cells, which would lead to false-negative results; (3) to meet the above-described criteria and to perform two homologous and one heterologous fusion experiment, 3×10^7 purified monocytes are needed, equivalent with 100 ml of whole blood.

To establish the different complementation groups, multiple blood samples from some patients may be needed. This would pose problems because most patients are small children. Therefore, we decided to try the most obvious complementation experiment, fusion of monocytes from an X-linked, cytochrome *b* negative male (patient 1) with those of a cytochrome *b* positive male (patients 2 and 3), to show not only the feasibility of monocyte hybridization but also the importance of cytochrome *b* for the activity of the O_2^-/H_2O_2 generating system. The results of these experiments are shown in Fig. 1 and Table 2.

Figure 1 clearly shows that NBT-positive hybrids were only found in the heterologous situation (expt *b*). The number of positive hybrids observed directly (0 h, Table 2, expt *d*) or shortly after (2.5 h, Table 2, expt *b*) fusion was already 30% of all hybrids, indicating that protein synthesis was not required for complementation in these particular experiments. Indeed, in an experiment parallel to expt *d* (Table 2), inhibition of protein synthesis with cycloheximide (1 μg ml^{-1}) had no effect on the percentage of positive hybrids up to 40 h (not shown). This finding, however, does not preclude the use of monocytes, because protein synthesis might be needed in other complementation groups. The decline in the number of positive hybrids after 40 h in expt *b* is probably due to deterioration of the hybrids. The percentage of positive hybrids at 15 h is very close to the expected maximal value of 50%, indicating that complementation only occurs when heterologous hybrids are formed. The homologous hybrids remained NBT negative, as did the non-fused cells of both patients. In separate experiments, we found that all monocyte hybrids from a single normal donor remained NBT positive, as did non-fused normal cells. Thus, we conclude that both types of CGD patient are genetically different, and that cytochrome *b* is most probably one of the corrective factors. Furthermore, monocyte hybridization experiments can provide information on the genetic background of

Table 1 Genetic heterogeneity in 17 patients with chronic granulomatous disease

	Mode of inheritance					
	X-Chromosomal cytochrome *b*		Autosomal recessive cytochrome *b*		Unknown cytochrome *b*	
	Positive	Negative	Positive	Negative	Positive	Negative
No. of male patients	(1)*	6	—	1	3	1
No. of female patients	—	—	—	2	2	1

CGD patients were diagnosed clinically by recurrent infections of skin, lungs and lymph nodes with catalase-positive bacteria and yeasts, and biochemically by failure of their blood granulocytes to mount a respiratory burst (O_2 consumption[13], NBT reduction (see legend to Fig. 1), H_2O_2 formation[14]) on incubation with opsonized zymosan or phorbol myristate acetate, and reduced capacity of these cells to kill opsonized *Staphylococcus aureus in vitro*. X-chromosome linkage is concluded from the detection of heterozygosity in the mothers and sisters of the patients (subnormal values for O_2 consumption and H_2O_2 production, subnormal amount of cytochrome *b*, and mosaicism in the NBT slide test). Autosomal recessive inheritance is concluded from the following findings. In this family one male and two female CGD patients were found; a sister showed heterozygosity in the metabolic parameters and in the amount of cytochrome *b* (41% of normal), but no mosaicism in the NBT slide test; the father and the mother (first cousins) had low-normal metabolic activity in their neutrophils, no mosaicism in the NBT slide test and 59% and 64%, respectively, of the normal amount of cytochrome *b*. 'Unknown' comprises the category of GCD patients whose parents, brothers and sisters were found to be normal with respect to metabolic and functional tests. The presence of cytochrome *b* was evaluated from optical difference spectra of dithionite-reduced neutrophils minus native neutrophils; the amount of cytochrome *b* was calculated from these spectra by using an absorbance coefficient of 106 mM^{-1} cm^{-1} at 425 nm and of 21.7 mM^{-1} cm^{-1} at 558 nm (ref. 15).

* The amount of cytochrome *b* in the neutrophils from this patient was not measured accurately due to a slight contamination of the cells with haemoglobin; this resulted in a double peak at 425 nm and 433 nm in the redox spectrum; thus, a partial deficiency of cytochrome *b* may exist.

Table 2 Expression of the NBT reductase activity in somatic cell hybrids of monocytes from three CGD patients

Time after fusion (h)	% of NBT-positive hybrids in fusion experiment				
	a(1×1)	*b*(1×2)	*c*(2×2)	*d*(1×3)	*e*(3×3)
0	—	—	—	32.1 (*n* = 6)	0 (*n* = 3)
2.5	2.5 (*n* = 2)	30.1 (*n* = 4)	1.7 (*n* = 3)	—	—
15	0 (*n* = 2)	43.6 (*n* = 10)*	0 (*n* = 2)	45.1 (*n* = 3)†	0 (*n* = 4)
40	0 (*n* = 2)	22.6 (*n* = 7)*	0 (*n* = 2)	35.1 (*n* = 4)†	0 (*n* = 2)
136	0 (*n* = 1)	25.9 (*n* = 4)*	0 (*n* = 1)	—	—

The percentage of NBT-positive hybrids was calculated as the percentage of the number of hybrids counted per 5,000 cells per slide (4–40 hybrids); 1 to 10 slides were evaluated. Results are in geometric means derived from the log-normally distributed values. Expts *a*, *b* and *c* are as in Fig. 1; expts *d* and *e* were performed 1 month later with a second blood donation of patient 1.

* Student's *t*-tests performed on the log-normally distributed values, corrected for separate variance estimates, indicated two-sided *P* values of 0.08 for 2.5 h versus 15 h, 0.003 for 15 h versus 40 h, and 0.5 for 40 h versus 136 h.

† Student's *t*-tests performed as described above. $P = 0.06$ for 0 h versus 15 h, and 0.2 for 15 h versus 40 h.

CGD patients. We feel that only a multi-centre follow-up of this study will lead to the elucidation of a full set of complementation groups within reasonable time, because it is impossible to obtain these large quantities of blood frequently from the relatively small number of patients in one institute. The establishment of complementation groups may well lead to a better understanding of the genetic defects underlying CGD.

We thank Dr A. Westerveld for valuable advice, Dr J. W. M. van der Meer for submission of two patients under his care to the hybridization experiments and Mr W. Schaasberg for statistical analysis. This study was supported by grant 13–39–40 from the Foundation for Medical Research FUNGO, which is subsidized by the Netherlands Organization for the Advancement of Pure Research (ZWO).

Note added in proof: Fusion of monocytes from patients 2 and 3, and of monocytes from patient 1, with another X-linked patient did not result in complementation even after prolonged culturing.

Amino acid sequence of rat submaxillary tonin reveals similarities to serine proteases

Claude Lazure, Richard Leduc, Nabil G. Seidah, Gaétan Thibault, Jacques Genest & Michel Chrétien

Clinical Research Institute of Montreal, 110 Pine Avenue West, Montreal, Canada H2W 1R7

Tonin[1], an esteroprotease isolated from rat submaxillary gland, is a serine protease with trypsin- and chymotrypsin-like activity. The substrate specificity of tonin shows that it differs from kallikreins and is definitely not a renin-like enzyme or an angiotensin-converting enzyme[2]. Tonin can produce directly the vasoactive peptide angiotensin II, from angiotensin I, angiotensinogen and the synthetic tetradecapeptide substrate of renin by cleavage of a Phe-His bond. It has also been found to cleave some Phe and Arg bonds in various substrates such as β-lipotropin (β-LPH), adrenocorticotropin (ACTH), pro-

0028-0836/84/060555—06$01.00

opiomelanocortin (POMC)[3] and substance P[4]. Here we describe the complete amino acid sequence of rat submaxillary gland, tonin. Comparison of the sequence of 219 amino acids with other serine proteases, particularly kallikreins, γ-subunit of nerve growth factor (NGF) and the recently described γ-renin, reveals extensive similarities. More interestingly, it also reveals the substitution of an Asp residue always found in the serine protease active site triad (Asp, His, Ser) by a Leu residue. This unusual substitution does not seem to affect the proteolytic activity of the enzyme.

Previous reports on the primary structure of rat tonin have shown that isoleucine and proline occupy the amino and carboxy termini respectively and that sequence analysis of 95 residues showed a very high homology to the serine protease family, especially to the γ-subunit of mouse NGF[5,6]. The complete amino acid sequence of submaxillary gland tonin has now been determined (Fig. 1). Tonin is a single polypeptide chain of 219 amino acids including 10 cysteines and having a molecular weight of 23,796. This molecular weight is much lower than those previously reported which were all in the region of 28,000–30,000 and obtained experimentally by gel filtration, high pressure gel permeation, sedimentation equilibrium and gel electrophoresis experiments[7,8]; this, in turn, led to an overestimation of the actual number of amino acids previously reported as 272[5]. The deduced sequence shown in Fig. 1 was obtained through analysis of the reduced and alkylated chain, of fragments derived from autolysis cleavages and from cyanogen bromide fragmentation. Details of the sequence, most of it done at the 10–20 nmol range, will be reported elsewhere (C.L. *et al.* in preparation).

Comparisons of tonin amino acid sequence with the published sequences of serine proteases (Table 1) show a very high homology (over 50%) between tonin and the various sequence of kallikrein including the pig pancreatic kallikrein[9], the murine glandular kallikrein deduced from a cloned cDNA fragment[10], the rat submaxillary kallikrein[11], which itself proved entirely homologous (117 out of 118 residues) to the rat pancreatic kallikrein deduced from the nucleotide sequence of the mRNA[12]. Moreover, the tonin sequence is also very similar to the γ-subunit of murine NGF[13] as proposed earlier[6] and also to another enzyme found recently in the mouse submaxillary gland, γ-renin[14]. Interestingly, the γ-renin can produce angiotensin I from the renin substrate tetradecapeptide, but not from the natural renin substrate, whereas tonin can act on both substrates to produce angiotensin II. It is thus quite clear, as judged by Table 1, that tonin, NGF γ-subunit, γ-renin and probably epidermal growth factor (EGF) binding protein, form a closely related group within the kallikrein family. That relationship has already been documented by Bothwell *et al.*[15] for glandular kallikrein and growth factor proteases of mouse submaxillary gland.

Looking at the actual sequence, it can be seen that the 10 half-cystine residues in tonin, when aligned to maximize homology can be found in similar positions in the NGF γ-subunit and in trypsin. From this alignment, the linkage of the disulphide bridges in tonin can thus be inferred so that Cys-7 is linked to Cys-131 (corresponding to trypsin 13 to 143), Cys-24 to Cys-40 (trypsin 31 to 47) which forms the 'histidine loop' responsible for proper orientation of the His residue in the active site, Cys-110 to Cys-177 (trypsin 115 to 216), Cys-142 to Cys-156 (trypsin 154 to 168) which forms the 'methionine loop', Cys-167 to Cys-192 (trypsin 179 to 203) which link together the primary and secondary binding sites. It can also be deduced that tonin, like the kallikreins, should not be expected to bind calcium ions since those residues in trypsin, namely Gln-58, Asn-60, Val-63 and Gln-68, are replaced in tonin by Arg-51, Asn-53, Lys-56 and Ala-61. It can also be deduced that tonin should not contain any carbohydrates, at least not the Asn-linked type, since the typical Asn-Xaa-Ser or Asn-Xaa-Thr recognition sequence cannot be found. This differs from pig pancreatic kallikrein where two glycosylation sites were found[9], from the NGF γ-subunit where one site was found[13] and possibly also from the rat

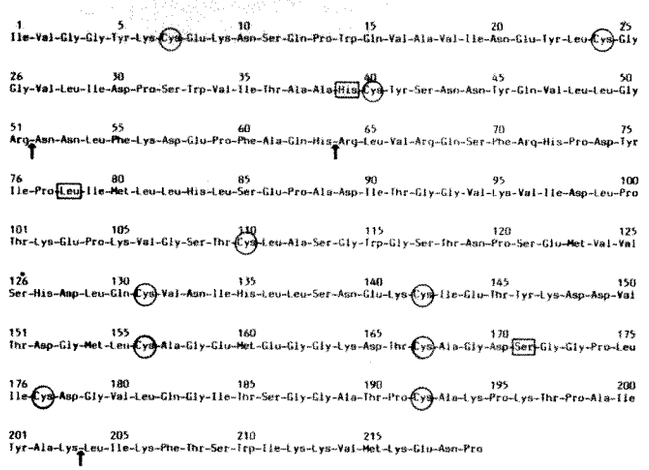

Fig. 1 Amino acid sequence of rat submaxillary gland, tonin. Cys residues are encircled and the residues localized at the active site are enclosed in boxes. Arrows indicate potential sites of autolysis. Positions 1–66 were obtained by sequencing the reduced and alkylated protein. Positions 64–86 were obtained by sequencing the autolysis fragment beginning at position 64. Positions 81–120 were given by the sequence of the cyanogen bromide-derived fragment starting at 81 and also of a fragment comprising residues 81–123. Positions 124–154 were obtained by sequencing the first 29 residues; the last two residues were localized as Gly-Met because position 154 is a CNBr cleavage site. Positions 155–200 and 161–200 were deduced by sequencing the respective cyanogen bromide fragments; positions 201–203 being deduced by amino acid composition. The last 15 residues were obtained by sequence of an autolysis fragment starting at position 204; the C-terminal Pro is deduced by amino acid composition and confirmed by previous studies[5].

pancreatic kallikrein where a glycosylation recognition sequence can be seen (see note added in proof).

All but two of the 29 invariant residues of the serine protease family are conserved in the tonin sequence including the His and Ser residues found in the active site. Indeed, the sequence Val-Leu-Thr-Ala-Ala-His-Cys, found in every serine protease, is present; it does contain a conservative substitution, namely the isoleucine at position 35 in place of the common leucine residue. The complete sequence Cys-Xaa-Gly-Asp-Ser-Gly-Gly-Pro-Leu surrounding the active site Ser is also found in tonin at positions 167–175. One of the exceptions is at position 135 where an His residue replaces Pro. This particular position is characteristically variable in kallikrein and kallikrein-related enzymes as shown by the presence of an Asp in rat pancreatic kallikrein, a Thr in the pig pancreatic and mouse submaxillary kallikrein and a Lys in the γ-subunit of mouse NGF and in the γ-renin. The other exception, at position 78, is more interesting since it involves the replacement of the Asp residue localized at the active site (corresponding to Asp-102 of chymotrypsin) by a Leu residue; this change will be discussed later. The Asp-189 of trypsin, thought to determine the substrate specificity, is also present at position 165 in tonin thus explaining its trypsin-like character. The secondary binding site corresponding to the sequence Ser-Trp-Gly (trypsin position 214–216) is localized at position 186–188 where the Trp is replaced by a Gly. The Gly at position 216 is conserved in tonin (position 188) whereas the Gly at position 226 is replaced by an Ala in tonin (position 199). Both residues are located at the entrance of the binding cavity.

When aligning the sequence to maximize homology, it is necessary to introduce a two-residue deletion between position 20 and 21 with respect to all kallikreins and kallikrein-related enzymes. Another deletion of the same length is introduced between position 120 and 121 compared with pig kallikrein. One of the most striking features of the tonin sequence is the presence of a sizeable deletion (Fig. 2) between residue 73 and 74. To accommodate other kallikrein sequences, is is necessary

to introduce a 16-residue deletion which accounts for the shortened chain length of tonin corresponding to 219 amino acids instead of the 237 of rat pancreatic kallikrein and the 233 of the NGF γ-subunit. The only other serine protease having a comparable deletion is human plasmin (Fig. 2). Moreover, this region of the molecule is particularly sensitive to autodigestion of the so-called 'kallikrein autolysis loop' leading to cleavages illustrated in Fig. 2. In the case of tonin, autodigestion was not observed in that region even though three sites of cleavage, some of them probably due to autolysis were identified at positions 51–52, 63–64, and finally 203–204 (Fig. 1). The most often encountered being the one at 63–64, which could indicate a conformation different from the one found in kallikreins. Presence of autolysis sites seems to occur in all members of the kallikrein family and in some serine proteases. The presence of fragments arising from autolysis which complicates the sequence determination greatly, can be clearly seen upon reduction and alkylation of the disulphide bridges of tonin, of the γ-subunit[16] and two serine proteases from the mouse submaxillary gland[17].

An important striking feature of the tonin sequence is the absence of the Asp residue corresponding to Asp-102 (chymotrypsin numbering) present at the active site and its replacement by a Leu residue. This latter substitution is also accompanied by substitutions of the amino acids surrounding it (Fig. 2). This result was entirely unexpected since, in all serine proteases known so far, the Asp residue is thought to participate actively in the enzyme mechanism by forming what is known as the 'charge-relay system'. The existence of such a relay has been challenged, but examination of crystallographic data shows that the Asp residue is sufficiently close to the His to favour intramolecular interactions. On the other hand, some recent theoretical considerations by Genest and Ptak[18] have shown that reinforced interactions between His and Ser, the latter being involved in the formation of the acyl-enzyme intermediate, must be accomplished with destabilization of the Asp-His diad. Also, Polgar and Bender[19] have suggested that the Asp-102 does not take part in the charge-relay system but may act solely to stabilize the imidazolinium intermediate. Moreover, the finding that papain, a thiol-protease containing His and Cys in the active site, reacts in a similar fashion to serine proteases could indicate that the Asp-102 might not be essential for proteolytic activity even though it might contribute to maintenance of a favourable conformation of the active site. On the other hand, it is clear that, even with such a substitution, tonin can act as a serine protease[2]. With angiotensin I as substrate, the *p*H optimum of tonin was 6.8[1] whereas, with small synthetic substrates *p*H 8–9 was obtained[2] which is similar to values obtained with other serine proteases. It is inactivated by, for example,

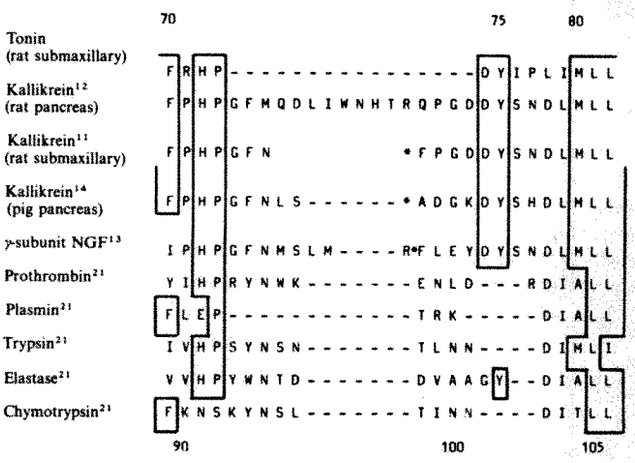

Fig. 2 Alignment of tonin 70–82 with corresponding segments of other serine proteases according to Dayhoff[15] (in the single letter code[24]). For ease of comparison, the numbering of chymotrypsin has been added below the alignment. The sign * in front of a sequence indicates the beginning of an observed autolytic fragment. Absence of dashes following a sequence indicates lack of sequence information.

diisopropylfluorophosphate (DFP) even though it requires much more DFP and longer incubation time for complete inactivation which could indicate modification around the active site as compared to other serine proteases. It is also able to cleave a certain number of Phe-Arg, Phe-Lys, Arg-Tyr, Arg-Trp, Phe-His, Phe-Phe and Phe-Gly bonds in various substrates. The only other substitutions known so far in active site residues concern the serine protease homologue, haptoglobin devoid of any proteolytic activity, where the triad His, Asp, Ser is replaced by Lys, Asp, Ala[20]. Another explanation could be that the 16-residue deletion together with other amino acid substitutions could induce a conformational change sufficiently important as to bring close to the histidine and serine, another acidic residue not adjacent to Asp-102 in the sequence, but close in the three-dimensional structure. Even though intriguing, this explanation is difficult to reconcile with a deletion of similar size localized in the region of the plasmin enzyme that contains the normally encountered aspartic residue.

Final conclusions concerning both the importance of the deletion and of the substitution of Asp by Leu, will have to rely on current research on the three-dimensional structure of the enzyme.

Table 1 Homologies between serine proteases and rat submaxillary tonin

Enzymes	Species	No. of residues Compared	No. of residues Identical	Homology %	Chain length
Kallikrein[9] (submaxillary gland)	Rat	118	89	75.4	—
Kallikrein[10] (pancreatic)	Rat	237	170	71.1	237
Kallikrein[11] (submaxillary gland)	Murine	149	97	65.1	—
γ-Subunit NGF[12]	Murine	233	150	64.4	233
γ-Renin[13]	Murine	73	46	63.0	—
Kallikrein[14] (pancreatic)	Porcine	232	119	51.2	232
Trypsin[21]	Bovine	229	92	40.2	223
Plasmin[21]	Human	237	83	35.0	229

The number of residues compared includes gap positions assigned to maximize homologies between the tonin sequence and the various proteases. Superscript numbers indicate the reference number.

This work was supported by a Group Grant and a Program Grant (PG-2) from the Medical Research Council of Canada and NIH (MS 16-315-03).. C.L. is a 'chercheur-boursier' of the 'Fonds de la Recherche en Santé du Québec'. We thank Ms D. Marcil for secretarial assistance.

Note added in proof: Since submission of this manuscript work has clarified uncertainties at position 119–123. The results (included in Fig. 1) revealed the presence of an Asn-Pro-Ser-Glu-Met which could lead to N-glycosylation even though Bause and Legler[25] have shown that the Asn residue in such a sequence cannot be glycosylated because of the vicinal Pro.

Computer-based characterization of epidermal growth factor precursor

Russell F. Doolittle, Da Fei Feng & Mark S. Johnson

Department of Chemistry, University of California, San Diego, La Jolla, California 92093, USA

The cDNA sequence of the precursor of mouse epidermal growth factor (EGFP) has recently been reported by two groups[1,2], both of whom noted the presence of repeated similar segments, each about 40 residues long. One of these repeat units overlaps with the sequence of epidermal growth factor itself. The sequence of epidermal growth factor has been reported to be similar to that of pancreatic secretory trypsin inhibitor[3] (PSTI) and a somewhat better match has been found with part of the sequence of bovine factor X[4], one of the blood coagulating factors. We report here that there is an even stronger similarity between the sequences of some of the repeat units of epidermal growth factor precursor and certain segments in factor X. This sequence similarity is also apparent in comparisons with other blood coagulation factors. On the basis of these sequence comparisons we suggest a scheme for the evolution of the epidermal growth factor precursor. We have also identified certain structural features in the precursor sequence that bear on the way in which the mature epidermal growth factor is generated.

The EGFP precursor sequence was searched against 1,081 sequences (~120,000 residues) in the 1978 Dayhoff *Atlas*[4] and about 800 sequences (~160,000 residues) in Newat[5]. The search identified bovine factors X and IX (in the Dayhoff *Atlas*), and human factors X and IX and bovine protein C (in Newat) as having matchable segments. In addition the search patterns revealed a repeat segment of 41 ± 2 residues in the queried sequence, in good agreement with the size of the homologous segments reported by Gray *et al.*[1] and Scott *et al.*[2].

Table 1 Resemblances between homologous units in mouse EGFP and two adjacent segments of bovine factor X

EGFP Segment (residue)	Factor X_A (residues 44–84) % Identity	NAS	(s.d.)	Factor X_B (residues 85–126) % Identity	NAS	(s.d.)
a (22–64)	17.1	159	(0.2)	21.4	238	(2.7)
b (327–361)	34.3	314	(3.6)	37.1	357	(2.6)
c (362–402)	34.2	402	(4.8)	31.7	463	(10.5)
d (403–442)	22.5	288	(2.0)	32.5	475	(9.7)
e (443–484)	17.1	220	(0.4)	42.9	488	(10.2)
f (747–788)	29.3	354	(6.2)	35.7	500	(9.8)
g (838–876)	23.1	359	(4.1)	18.0	282	(1.5)
h (877–918)	31.7	354	(4.3)	26.2	286	(2.0)
i (919–960)	34.2	402	(6.2)	14.3	238	(1.3)
j (977–1,020)	31.7	378	(4.7)	19.1	238	(0.9)

Segments were compared by a computer program using a similarity measure based on the original algorithm of Needleman and Wunsch[6]. The normalized alignment score (NAS) reflects a penalty 2.5 × the value of every match (10 points) (Cys matches, 20 points); it is adjusted for 100 residues. Scores over 150 usually indicate common ancestry[5]. The statistical likelihood of chance resemblance was empirically determined by comparing multiple jumbled sequences of the same lengths and compositions. If the alignment score of the genuine sequences is greater than 3.0 standard deviations (s.d.) above the mean of the jumble comparisons, common ancestry is generally inferred[5]. In contrasting *A* and *B*, the higher NAS is underlined in each case. Note that EGFP segments *a–f* are more closely related to factor X segment *B*, whereas *g–j* more closely resemble factor X segment *A*. EGFP segment *j* overlaps the known sequence for EGF itself.

The nine segments from EGFP noted by Gray *et al.*[1] were designated *b–j*; a tenth homologue was denoted '*a*' (Fig. 1). The two corresponding segments in the zymogen proteases were denoted *A* and *B* (Fig. 2). The sequences were compared by both similarity[6] and difference[7,8] types of computer alignment schemes. Each segment was compared with every other, and various phylogenetic trees were constructed[9]. Comparisons of the 10 homologous EGFP units with the factor X segments are given in Table 1. Interestingly, the units nearer the amino terminus more closely resemble segment *B* of factor X than they do segment *A*, whereas the inverse is true of the units nearer the carboxy terminus.

The similarities of EGFP units *c–f* to factor X segment *B* are such that the authentic alignment scores lie +10 standard deviations above the average of comparison sets made with jumbled sequences of the same lengths and compositions (Table 1). These similarities are of the same degree as lysozyme–lactalbumin or insulin–relaxin[5] and are significantly better matches than the previously reported homology of EGF and PSTI (3) or, for that matter, EGF and factor X (4).

Several other homologies in EGFP were overlooked in the recent cDNA reports. There is a subtle but very significant homology between two large sections of the precursor sequence that are not in the cysteine-rich units (Fig. 1). The segment denoted *x* (residues 121–310) has a 30% identity with the segment denoted *y* (residues 561–746) (Fig. 1). It seems very likely that these two segments arose by internal duplication, a score of greater than +10 standard deviations being achieved when jumbled sequences of the same lengths and compositions were compared. In addition, there are four other shorter sequences that have similar sequences to each other; these are denoted *q–t* in Fig. 1.

There are a number of alternative explanations for the present structure of the EGF precursor. For example, it may have begun with a translocation of an 80-residue segment from the amino terminal region of factor X or a related zymogen. In this case the existence of the already duplicated segment (X_{AB}), would increase the chances of further mismatching and unequal crossing over. It is also possible that EGFP is the indirect result of

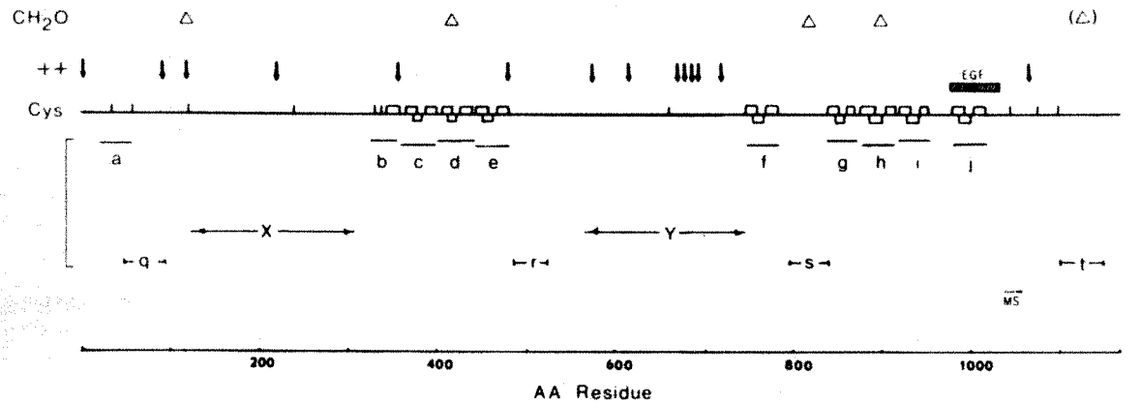

Fig. 1 Schematic depiction of mouse epidermal growth factor precursor (EGFP). The putative protein has 1,168 amino acids[1] (another report[2] suggests a sequence of 1,217 residues, but a comparison of the two cDNA sequences indicates that a difference of one base at position 3,751 puts the sequences out of register near the carboxy terminus). Three different kinds of homologous segments have been identified (*a–j*; *x–y*; *q–t*). These include nine previously noted homologous units designated *b–j*, and a tenth unit, less obvious, denoted *a*; EGF (residues 977–1,029) overlaps unit *j*. Two longer segments in EGFP are also homologous and are designated *x* and *y*. Finally, four other short segments are similar to each other and are denoted *q-t*. The disulphide bond arrangements in units *c–i* are patterned on the known arrangement in EGF (unit *j*). Other cysteines (Cys), including one in a predicted membrane-spanning segment (residues 1,039–1,059), have been left unpaired even though most are likely in the form of disulphide bonds. Triangles indicate consensus carbohydrate-attachment points; if the model described in the text is correct, only those situated outside the plasma membrane will be derivatized. Arrows denote 'double-basic' (Arg–Arg, Arg–Lys, and so on) potential proteolysis points.

Fig. 2 Alignment of segments *A* and *B* from blood coagulation zymogens and 10 homologous segments from epidermal growth factor precursor (EGFP). Cysteine residues are shown in lower case. Underlined segments are predicted as turns by two different computer programs (broken lines predicted by only one of the two predictive programs). See Fig. 1 for locations of EGFP segments.

two separate exchanges with the factor X gene. This interpretation is in better agreement with the observation that all the homologus EGFP peptide segments nearer the amino terminus resemble unit *B* in factor X more than they do unit *A*, whereas the inverse is true of the segments nearer the carboxy terminus. If a DNA segment encoding an 80-residue previously duplicated twin had been the initiating material, then one might have expected, in whole or part, an alternating arrangement of homologous segments according to how much they resembled factor X_A and X_B, respectively.

The EGFP sequence was subjected to analysis by computer programs thought to be predictive of secondary structure[10,11]. We were particularly interested in predicting 'turns', which are among the more accurately assignable features in proteins, for if the disulphides in each of the homologues exist in the same arrangements as occur in EGP[12], then they would be constrained to turn back on themselves three times. In fact, the remarkable agreement of predicted turns in the 10 homologues (Fig. 2) suggests that all of the units are tightly folded and that the disulphide pairings within them are similar. The six-cysteine 40-residue segments being examined here should not be confused with the six-cysteine 80-residue configurations commonly referred to as 'kringles', of which prothrombin contains two, but factor IX, factor X or protein C apparently contain none[13].

The 1,168-residue sequence of EGFP was also analysed by a computer program that provides a moving average of its hydropathy[14]. The profile closely resembled those of known membrane-attached glycoproteins[15] in that a likely membrane-spanning segment was predicted for residues 1,039–1,058. In addition, a characteristic signal peptide was projected for residues 9–29, as suggested by Scott *et al.*[2]. EGFP may exist on the surface of the cells of its origin, anchored by the spanning segment, and with residues 1,060–1,168 remaining inside the cell. Release of active EGF would occur as the result of limited proteolysis of the tethered precursor.

The known active EGF molecule corresponds to the 53-residue segment numbered 977–1,029. The segment is obviously released from the precursor (or some fragment thereof) by cleavage of an arginyl–asparagine bond at its amino terminus and an arginyl–histidine bond at its carboxy terminus. Neither of these dipeptidyl junctions occurs at equivalent positions around the other nine homologous segments, nor, do arginyl junctions of any type. In fact, if the disulphide pairing is analogous to that known to exist in EGF (segment *j*), then there is no possibility that tryptic-like cleavages would release EGF-like fragments from the nine homologues.

The topology of a computer-derived tree indicates that EGFP evolved before or about the time of the divergence of factors IX, X and protein C but definitely after their divergence from prothrombin. These particular blood coagulation zymogens belong to a small subset of vertebrate plasma proteins that contain clusters of the unusual amino acid γ-carboxyglutamic acid near their amino termini. The duplicated segments under discussion here are actually adjacent to the γ-carboxyglutamic acid region. Protein C and factors IX and X also contain the unusual amino acid β-hydroxyaspartic acid[16,17], and in this case the unusual amino acid is actually situated in segment *A*. None of the EGFP homologous units has aspartic acid at the equivalent positions, however.

The divergence times can also be estimated from a consideration of the sequence differences between mouse and human EGF[4]. Knowing that rodents and primates last shared a common ancestor 80 Myr ago, and that the sequences of their EGFs differ in 17 of 53 residues, we can estimate an approximate rate of change. If we assume that the EGF-like units in the rest of the precursor protein have been changing at about the same rate, then the two most similar of these units, *c* and *d*, which differ by about 60%, diverged about 200 Myr ago. Two quite dissimilar units, *b* and *g*, are 80% different and by this measure would have diverged about 500 Myr ago. However, the (presumably) non-functional homologues may have been changing significantly faster than EGF itself. Nonetheless several of the homologous units resemble the zymogen segments more closely than does EGF. Given common ancestry, they have either been more rigorously conserved or have diverged on an independent and more recent occasion.

By either of these criteria EGF is an early vertebrate creation. The data agree with a gene encoding a segment of some primitive factor X-like molecule having been partially duplicated and translocated elsewhere in the genome. The transferred unit, whether corresponding to a 40- or an 80-residue segment, may have included parts of surrounding introns that subsequently became expressible as a result of the translocation. It seems reasonable that this new unit encoded a membrane-anchored protein from its inception and that limited proteolysis released a primitive EGF-like molecule. By chance the gene produced must have bound, however weakly, to an existing receptor for some other (growth) factor. Interestingly, factor IX binds to several cell types including fibroblasts[18]. From that point on the receptors and growth factors diverged in parallel, as is observed for many other biological systems. The existence of two similar sequences in the originally transposed unit would have facilitated further mismatching and tandem elongation.

It has recently been reported that a tumour growth factor from several sources is homologous with EGF[19]. The degree of similarity found is less than that observed between several of the EGP homologues and the corresponding segments in the zymogen clotting factors. Although the full sequences of these tumour growth factors are not known, the data available suggest that they are about 30% similar to EGF itself; the resemblance is less when the tumour growth factors are compared with any of the EGFP homologues (*a–i*), suggesting that the tumour growth factors have not arisen directly from any of the other homologus units in EGFP. Rather, it is consistent with the tumour growth factor and EGFP arising as the result of duplication of a common ancestral gene. As such it can be expected that they will also have precursors that are anchored in the membranes of their cells of manufacture and will be activated by a scheme of extracellular proteolysis.

Among the pathological effects in man following infection with *Mycoplasma pneumoniae* is a transient autoimmune disorder characterized by the presence of high-titre erythrocyte autoantibodies (cold agglutinins)[1,2]. These autoantibodies are usually directed against the carbohydrate antigen termed I (ref. 3) which consists of a branched oligosaccharide[4,5]. The mechanism by which the anti-I antibodies are elicited is unknown. However, sialic acid-containing receptors have been implicated in the adherence of *M. pneumoniae* to erythrocytes and other cell types[6], and both I and the related antigen i occur on erythrocytes in sialylated form[7]: i is the predominant antigen on fetal erythrocytes and I is predominant in adults[8]. Anti-I antibodies might arise in *M. pneumoniae* infection in response to a modification of the 'self' antigen-I as a result of its interaction with this agent[9,10]. Here we report our study of the specificity of the interaction of *M. pneumoniae* with human erythrocytes. We found that this interaction is mediated by long chain oligosaccharides of sialic acid joined by α2–3 linkage to the terminal galactose residues of poly-*N*-acetyllactosamine sequences of Ii antigen type.

Antigen I is built of repeating *N*-acetyllactosamine (Galβ1-4G1cNAc) units as in structure *a* below[4,5] and antigen i of linear poly-*N*-acetyllactosamine sequences[11] as in structure *b* (Gal, galactose; Glc, glucose; GalNac, *N*-acetylgalactosamine; GlcNAc, *N*-acetylglucosamine; NeuAc, *N*-acetylneuraminic acid; NeuGc, *N*-glycolylneuraminic acid).

Structure *a*

Galβ1-4GlcNAcβ1-3Galβ1-4GlcNAcβ1-3Galβ1-4GlcNAc/Glc Structure *b*

The importance of sialic acid as a component of the erythrocyte receptor for *M. pneumoniae* was confirmed by the reduction of the binding of neuraminidase-treated erythrocytes to 10% of that of untreated erythrocytes (Table 1). The preferen-

Table 1 Comparison of the binding of native, 'asialo' and resialylated erythrocytes to sheet cultures of *M. pneumoniae*

Erythrocytes	*N*-acetylneuraminic acid (nmol ml^{-1}) Content	Incorporated	c.p.m. added ($\times 10^{-3}$)	c.p.m. bound ($\times 10^{-3}$)	% Binding
Native	720		5,100	97.5	2
'Asialo'	40		4,500	8.9	0.2
Resialylated					
Galβ1-4/3GlcNAc |α2,3 NeuAc		75	1,100	151	13.6
Galβ1-4GlcNAc |α2,6 NeuAc		75	4,500	71	1.6
Galβ1-3GalNAc |α2,3 NeuAc		260	3,900	19	0.5

Human blood group O erythrocytes of I type were desialylated[38,39] using neuraminidase from *Vibrio cholerae* (Behringwerke) which released approximately 95% of the total sialic acid. Resialylation was achieved using donor CMP-NeuAc and one of the following purified enzymes: Galβ1-3/4GlcNAc α2-3-sialyltransferase[40,41], Galβ1-4GlcNAc α2-6-sialyltransferase[40,41] and Galβ1-3GalNAc α2-3-sialyltransferase[42]. The *N*-acetylneuraminic acid (NeuAc) content (per ml of packed cells) was estimated as described previously[38]. For radiolabelling, erythrocytes (1×10^9) were washed twice in Tris-buffered saline (TBS) containing 0.14 M NaCl, 1 mM $MgCl_2$, 0.1 mM $CaCl_2$, 0.01 M Tris-HCl *p*H 7.2 and incubated at 37 °C for 45 min with 100 μl of TBS containing 500 μCi sodium ^{51}Cr-labelled chromate (350–600 mCi mg^{-1} Cr) (Amersham). The cells were washed three times and resuspended in 100 μl of TBS. ^{51}Cr incorporation was in the range $1–10\times10^7$ c.p.m. per 1×10^9 erythrocytes as determined using a LKB Wallac 80,000 γ-counter. Sheet cultures were obtained using a strain of *M. pneumoniae*, MY 9862, which had been passed 10 times in mycoplasma liquid medium[43], once in hamster lung and then twice more in mycoplasma medium. Sheet cultures were prepared in 16×24 multiwell plates (Costar) by inoculating with 0.25 ml actively growing *M. pneumoniae* liquid culture (2.5×10^6 colour-changing units) per well containing 1 ml mycoplasma liquid medium. Plates were incubated at 37 °C until confluent sheets were obtained (3–4 days). The protein content of washed mycoplasma sheets, after solubilization in 1 M NaOH, was 20–30 μg per well; this was determined[44] using bovine serum albumin as a standard. For binding assays, the mycoplasma monolayers or uninoculated wells containing medium alone were washed twice with 1 ml TBS, then ^{51}Cr-labelled erythrocytes (1×10^7 cells in 300 μl) were added (in triplicate). The c.p.m. added varied with the erythrocyte preparations due to their differing incorporation of ^{51}Cr. The plates were incubated at 37 °C for 1 h and unattached erythrocytes were removed by washing each well with 3×1 ml of TBS. The attached erythrocytes in each well were solubilized in 1 ml of 1 M NaOH and the radioactivity counted for 30 s. The radioactivity bound to medium control wells (0.2–0.5% of c.p.m. added) was subtracted from that bound to the mycoplasma monolayers.

tial binding of *M. pneumoniae* to sialic acid joined by α2–3 linkage to galactose was clearly shown with the resialylated erythrocytes as follows. First, compared with 'asialo' erythrocytes, those having the NeuAcα2-3Galβ1-4/3GlcNAc sequence had a 68-fold greater binding while those having the NeuAcα2-6Galβ1-4GlcNAc and NeuAcα2-3Galβ1-3GalNAc sequences had only 8- and 2.5-fold greater binding, respectively (Table 1). Thus, erythrocytes having the NeuAcα2-3Galβ1-4/3GlcNAc sequence had 8.5-fold greater binding than those with the NeuAcα2-6Galβ1-4GlcNAc sequence. Second, compared with the native erythrocytes, the NeuAcα2-3Galβ1-4/3GlcNAc-derivatized erythrocytes showed almost sevenfold greater binding despite their lower sialic acid content. A major sialylated product obtained with the Galβ1-4/3GlcNAc α2-3-sialyltransferase (unpublished observations) as with the Galβ1-4GlcNAc α2-6-sialyltransferase[12], corresponds to band 3 glycoprotein. Thus, the supranormal binding of erythrocytes derivatized using the Galβ1-4/3GlcNAc α2-3-sialyltransferase can be explained in terms of the derivatization of band 3 oligosaccharides that are not naturally sialylated to this extent. Third, erythrocytes derivatized using the Galβ1-3GalNAc α2-3-sialyltransferase showed negligible binding above the 'asialo' erythrocytes despite their greater than six-fold content of sialic acid. This enzyme acts predominantly on the 0-glycosidically linked oligosaccharides of glycophorin A[12].

The specificity of the *M. pneumoniae*–erythrocyte interaction was next investigated using oligosaccharides and glycoproteins as inhibitors of binding (Table 2). The preference for sialic acid α2-3-linked rather than α2-6-linked to galactose as a receptor, sequence was confirmed with the two α2-3-linked isomers (Table 2, structures *d* and *f*) which were seven and nine times, respectively, more active as inhibitors than the corresponding α2-6 isomers (Table 2, structures *e* and *g*). Moreover, sialic acid α2-6-linked to *N*-acetylgalactosamine was ruled out as a receptor sequence for *M. pneumoniae* as none of the three submaxillary mucins tested gave inhibition. These glycoproteins are known to contain sialic acid predominantly α2-6-linked to *N*-acetylgalactosamine[13–16].

In its strong preference for sialic acid α2-3-linked to galactose residues, *M. pneumoniae* differs from *Mycoplasma gallisepticum* which does not distinguish between sialic acid α2-3-linked to galactose or α2-6-linked to *N*-acetylgalactosamine[17]. In contrast to our findings with *M. pneumoniae* (Table 2), the submaxillary mucins of ovine, bovine and porcine origins were found[17] to be effective inhibitors of the binding of *M. gallisepticum* to erythrocytes.

The trisaccharide sequence α2-3-*N*-acetylneuraminosyllactosamine (Table 2 as in structure *d*) was almost three times as active as α2-3-*N*-acetylneuraminosyllactose (structure *f*) indicating that *N*-acetylglucosamine is part of the receptor sequence. The inhibition experiments summarized in Table 2 show the strikingly strong inhibitory activity of oligosaccharides and glycoproteins containing the repeating *N*-acetyllactosamine sequence. Thus, oligosaccharide structure *c* containing two *N*-acetyllactosamine units was five times more active than structure *d* with a single unit. Similarly, among the glycoproteins tested, the most potent inhibitors were the polyglycosyl peptides of human erythrocytes (largely derived from bands 3 and 4.5) and the bovine erythrocyte glycoprotein GP-2, both of which are rich in branched poly-*N*-acetyllactosamine sequences of I antigen type (refs 18–20 and Y. Suzuki, H. C. Gooi & T.F., unpublished observations). Human glycophorin A and α_1-acid glycoprotein were substantially less active and fetuin was inactive, in accordance with their lack of poly-*N*-acetyllactosamine sequences[21–26]. Inhibition experiments with glycolipids (to be described elsewhere) have also indicated that sialylated poly-*N*-acetyllactosamine sequences are the preferred sequences for *M. pneumoniae* binding and that the sialic acid residues can be of *N*-acetyl or *N*-glycolyl type.

Although our results and those of others[27,28] have shown that solubilized glycophorin A as well as glycolipids and oligosaccharides having short chain sequences can inhibit the binding

of erythrocytes to *M. pneumoniae*, the following experiments showed that they do not serve as receptors for this agent on intact erythrocyte membranes. First, glycophorin-deficient cells, termed En(a$^-$), showed normal mycoplasma binding (Table 3); these cells have a 30–50% reduction in their sialic acid levels[29,30]. Second, following Pronase digestion of erythrocytes, which results in the loss of almost all the glycosylated portions of the major sialoglycoproteins (D. J. Anstee & M. J. A. Tanner, personal communication) but not of band 3 protein[31], the binding of mycoplasma was not reduced and was even slightly increased (Table 3). The carbohydrate chains of band 3 protein, but not those of the sialoglycoproteins, are known to contain poly-*N*-acetyllactosamine sequences having I antigen activity[19,20]. Third, erythrocytes treated with endo-β-galactosidase showed reduced binding to the *M. pneumoniae* sheets (Table 3), indicating that long chain, poly-*N*-acetyllactosamine sequences of Ii type[32] are the main receptors for this agent. The reduction in binding reflected the content of endo-β-galactosidase-susceptible poly-*N*-acetyllactosamine sequences in the three cell types as follows: the binding of normal and En(a$^-$) erythrocytes of I type was reduced to 44% and 43%, respectively, of untreated cells (Table 3), in accordance with the predominance in these cells of branched oligosaccharides of poly-*N*-acetyllactosamine type which are only partially susceptible[20,33] to endo-β-galactosidase. The availability of the variant erythrocytes of i-antigen type provided the strongest evidence for the importance of sialylated poly-*N*-acetyllactosamine sequences as receptors for *M. pneumoniae*. Cells of i type have a high content of linear poly-N-acetyllactosamine sequences which are more susceptible to digestion with endo-β-galactosidase than the corresponding branched sequences on erythrocytes of I type[20,33]. The binding of these cells was reduced by 85% following treatment with endo-β-galactosidase. This is remarkable as only 5% of the total erythrocyte sialic acid is released by this glycosidase[20]. Thus, minor sialylated oligosaccharides of the poly-*N*-acetyllactosamine series, such as those carried by glycoprotein bands 3 and 4.5, and glycolipids[20] are the main receptors for *M. pneumoniae* rather than the carbohydrate chains of the major sialoglycoproteins which are not susceptible to digestion by endo-β-galactosidase.

Table 2 Inhibition of binding of ^{51}Cr-labelled erythrocytes to sheet cultures of *M. pneumoniae* by oligosaccharides and glycoproteins

Designation	Inhibitors: Oligosaccharides	Concentration*
c	Galβ1-4GlcNAcβ1-3Galβ1-4GlcNAc-Asn \|α2,3 NeuAc	16
d	Galβ1-rGlcNAc-Asn \|α2,3 NeuAc	88
e	Galβ1-4GlcNAc-Asn \|α2,6 NeuAc	640
f	Galβ1-4Glc \|α2,3 NeuAc	245
g	Galβ1-4Glc \|α2,6 NeuAc	2,136
h	NeuAc	NA
j	Galβ1-4Glc†	NA
	Glycoproteins	
	Polyglycosyl peptides	0.9
	Bovine erythrocyte sialoglycoprotein (GP-2)	2.5
	Glycophorin A	12.6
	α_1-acid glycoprotein	47.7
	Bovine fetuin	NA
	Submaxillary mucins; bovine, ovine, porcine	NA
	Bovine serum albumin†	NA

Structures *c*, *d* and *e* (asparaginyl oligosaccharides) were isolated from the urine of patients with aspartylglucosaminuria (J-C.M., J. Montreuil, G. Strecker, H. van Halbeek and J. Vliegenthart, in preparation). Structure *g*, NeuAcα2-6 isomer of sialosyllactose, isolated from human milk, was given by the late Dr Adeline Gauhé. Structure *f*, NeuAcα2-3 isomer of sialosyllactose, and structure *j*, *N*-acetylneuraminic acid and lactose, were from Sigma. The preparation of α2-6 isomer of sialosyllactose was found to contain 11% free *N*-acetylneuraminic acid and the preparation of α2-3 isomer contained 10% α2-6 isomer as assessed by HPLC[45]. The inhibition values shown for these two isomers of sialosyllactose have been corrected to allow for the impurities. Polyglycosyl peptides, obtained by pronase digestion of human erythrocyte membranes[18], were given by Dr J. Finne; the sugar composition and their molar ratios were fucose 3.6: mannose 3.0: galactose 13.9: *N*-acetylglucosamine 15.5: *N*-acetylneuraminic acid 2.8, (approximately 3 mol mannose per mol glycopeptide). The bovine erythrocyte sialoglycoprotein, GP-2, which is a strong inhibitor of haemagglutination by Sendai virus[46], was given by Dr Y. Suzuki. This glycoprotein contains 70% carbohydrate by weight; the monosaccharides *N*-acetylgalactosamine, *N*-acetylglucosamine, galactose and sialic acid (*N*-glycolylneuraminic acid 96%; *N*-acetylneuraminic acid 4%) are present in molar ratios of 1.0:4.0:5.2:2.9. The backbone sequence is deduced to be a branched poly-*N*-acetyllactosamine structure from the strong I antigen activity expressed on asialo GP-2 (Y. Suzuki, H. C. Gooi & T.F., unpublished observations). Glycophorin A from human erythrocyte membranes[47] was a gift of Dr C. G. Gahmberg. Human α_1-acid glycoprotein was a gift from Dr K. Schmid. Bovine fetuin type IV was from Sigma. Ovine submaxillary mucin was from Dr D. van den Eijnden; bovine and porcine submaxillary mucins from Drs A. Corfield and R. Schauer; and bovine serum albumin (fraction V) from Miles Laboratories. Inhibition of binding assays were performed as follows: washed mycoplasma monolayers were preincubated with 300 μl of serial dilutions of inhibitors(in triplicate) in TBS at 37 °C for 1 h before the addition of 300 μl of ^{51}Cr-labelled erythrocytes (1×10^6 cells containing $1–10\times10^4$ c.p.m.). All subsequent steps were as for the binding assays (Table 1). Inhibition was calculated as the per cent reduction in binding relative to control wells which contained no inhibitor.

NA, No inhibition at the highest levels tested as follows: NeuAc 3,236 nmol; bovine fetuin 292 nmol sialic acid; submaxillary mucins; bovine 1,070, ovine 1,050 and porcine 470 nmol sialic acid. The relatively high inhibitory activities of the glycoproteins reflect the cooperative effects of multivalence of their carbohydrate chains.

* Concentration expressed as nmol sialic acid ml^{-1} giving 50% inhibition.

† Lactose, structure *j* (2,900 nmol oligosaccharide) and the non-glycosylated protein; bovine serum albumin (1 mg) served as non-sialylated controls.

Table 3 Effect of Pronase and endo-β-galactosidase treatment on binding of ^{51}Cr-labelled erythrocytes of OI, Oi and En(a$^-$) types to sheet cultures of *M. pneumoniae*

Erythrocytes	c.p.m. added ($\times10^{-2}$)	c.p.m. bound ($\times10^{-2}$)	% Binding
OI-untreated	800	57	7.1
Pronase	800	72	9.0
Endo-β-galactosidase	1,000	31	3.1
Oi adult-untreated	1,000	68	6.8
Endo-β-galactosidase	600	6	1.0
En(a$^-$)-untreated	1,000	71	7.1
Endo-β-galactosidase	1,000	30	3.0

Blood group OI erythrocytes were from a normal donor. Blood group O erythrocytes of the rare i phenotype[48] were from an adult deficient in I antigen [Oi (adult)]. Erythrocytes from an adult genetically deficient in the major erythrocyte sialoglycoprotein, glycophorin A (designated En(a$^-$)[49]) were given by Dr D. Anstee. For treatment with endo-β-galactosidase, 150 μl packed erythrocytes were washed three times in PBS and incubated at 37 °C for 3 h with 50 μl of PBS containing 6 mU of endo-β-galactosidase from *Bacillus fragilis*[50]. This enzyme cleaves poly-*N*-acetyllactosamine-type oligosaccharides containing the sequence GlcNAcβ1-3Galβ1-. The cells were then washed three times in PBS. For treatment with Pronase (Sigma, type VI), 150-μl packed cells were incubated at 37 °C for 30 min with 150 μl PBS containing 2 mg ml^{-1} Pronase; they were then washed three times in PBS. Radiolabelling of the untreated and enzyme-treated erythrocytes with ^{51}Cr and binding to mycoplasma monolayers was as described in the legend to Table 1; 3×10^6 erythrocytes were added to each monolayer.

The present studies further support the concept that the post-infective autoantibodies (anti-I) elicited following infection with *M. pneumoniae* occur as a result of the interaction of I antigen with the mycoplasma and the presentation of this 'self' antigen in an immunogenic form to the immune system of the host. This was first suggested in 1969 when we (T.F., D.T-R. and colleagues) immunized rabbits with human group OI erythrocytes which had been treated with live *M. pneumoniae* and about 30% of the rabbits developed high titres of anti-I antibodies[34]. More recently, we have obtained evidence that *M. pneumoniae* cultures absorb I-active glycolipids from serum-containing culture media. These observations now account for previous reports of I-antigen activity associated with laboratory strains of *M. pneumoniae*[35,36].

In view of the observation that *M. pneumoniae* can react with erythrocytes of both I and i type, it is intriguing that anti-I

antibodies rather than anti-i antibodies are elicited following infection with this agent. A possible explanation is that *M. pneumoniae* infection occurs usually in children and adults rather than neonates[37] and the i type oligosaccharides of fetal erythrocytes are largely replaced by I type structures in the first year of life[8,20]. Thus *M. pneumoniae* would encounter and adhere to I- rather than i-type erythrocytes and possibly other cells of I type in the inflamed bronchial epithelium.

The principles established with the *M. pneumoniae*–erythrocyte receptor system could apply to a variety of receptor systems where inhibition and cell binding data have been difficult to reconcile. Also, the complexing of adhesive molecules of infective agents to specific saccharides of host cell membranes may be an important mechanism for the eliciting of auto-antibodies with anti-receptor specificities.

L.M.L. holds a MRC PhD studentship; K.U. was a Guest Research Fellow of the Royal Society and P.R.S. is supported by the Cancer Research Campaign. We thank Drs A. Corfield, D. van den Eijnden, J. Finne, C. G. Gahmberg, J. Montreuil, Y. Nagai, R. Schauer, K. Schmid and G. Strecker for providing valuable glycoproteins, glycolipids and oligosaccharides and Mrs Maureen Moriarty for help in preparing the manuscript.

African trypanosomes evade clearance in immune-competent hosts by periodically replacing their major surface glycoprotein with an antigenically different glycoprotein[1–4]. Expression of many of these variant surface glycoproteins (VSGs) is associated with the duplication and transposition of silent basic copy genes (BCs) into unlinked genomic expression sites[5–10]. The new expression-linked VSG gene copies (ELCs) are oriented with their 3′ ends proximal to chromosome telomeres[11–14]. Other VSG genes are activated without the production of an ELC[10,15–18]. The 3′ ends of these VSG genes are near chromosome telomeres both when they are active and when they are inactive. Recently, we have shown that activation of the VSG-1 gene in the BoTaR (Bordeaux trypanozoon antigen repertoire) serodeme of *Trypanosoma equiperdum* involves the duplication and transposition of a telomeric BC gene into one of at least three unlinked telomeric sites[9]. Here we show that the VSG-1 ELC is inactivated but not eliminated in some antigenic variants derived from a VSG-1 expressor. In addition, a subsequent variant that again expresses VSG-1 has not reactivated the residual VSG-1 ELC (R-ELC), but instead contains a new, active VSG-1 ELC in an unlinked telomeric site. These results show that the simple presence of an ELC in a potential expression site is not sufficient for its expression.

We examined the fate of the VSG-1 ELC in *T. equiperdum* variants isolated from a rabbit infected with VSG-1 expressor BoTat-1 (Bordeaux trypanozoon antigen type-1). Figure 1*a* explains the genealogy of these trypanosome clones. Trypanosomes expressing VSG-1 always appear in the first peak of parasitaemia in rabbits infected with any variant from the BoTaR serodeme of *T. equiperdum*[4]. VSG-2 and -4 expressors also appear very early, whereas VSG-20, -28 and -78 expressors appear later in such infections. Figure 1*b* compares the hybridization profiles of the DNAs from these trypanosomes after digestion with *Bam*HI endonuclease, which does not cleave within the VSG-1-coding sequence, and hybridization to a ^{32}P-labelled VSG-1-specific cDNA clone.

As described previously[9], the profile of BoTat-1 showed four fragments, one of which contained the VSG-1 ELC (14 kilobases, kb), whereas the profiles of BoTats-20, -28 and -78 each showed only three fragments hybridizing to the VSG-1 cDNA. Surprisingly, the hybridization patterns of BoTats-2 and -4 also contained a fourth VSG-1-related band. DNA from BoTat-4[(20)], a second VSG-4-expressing variant derived from BoTat-20, showed only three *Bam*HI fragments hybridizing to the VSG-1 probe (Fig. 1*b*). Thus, the supplementary VSG-1-related sequences in the DNAs of BoTats-2 and -4 were not necessary for expression of the early VSGs.

The above results suggested that the supplementary VSG-1 sequences in BoTats-2 and -4 represented inactive residual VSG-1 ELCs (R-ELCs). To examine this possibility, restriction maps of the regions containing the apparent R-ELCs in these variants were constructed as described in Fig. 2 legend. The 5′ genomic environments of the R-ELCs seemed to be identical to that of the original VSG-1 ELC in BoTat-1, at least as far as the *Sal*I site more than 9 kb upstream from the gene. The restriction maps of the coding regions of the R-ELCs and the BoTat-1 ELC were also identical. Moreover, like both the

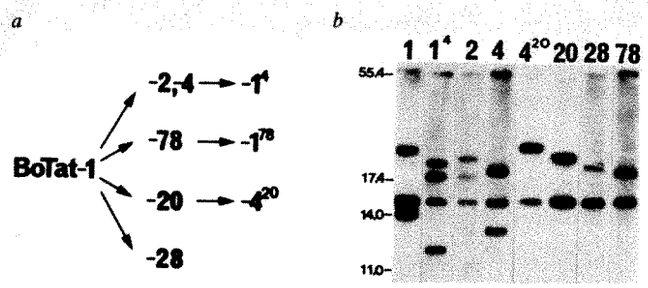

Fig. 1 *a*, Genealogy of trypanosome variants. All the *T. equiperdum* variants described here were derived from BoTat-1 as described by Capbern *et al.*[4]. Arrows represent infection of a rabbit with the designated variant. The variants were then isolated from the rabbits and cloned in mice. The variants are labelled here and in subsequent figures according to their numbers: 2 refers to BoTat-2 which expresses VSG-2, etc. BoTats-2 and -4 were isolated from the same rabbit. BoTat-1$^{(4)}$ was isolated from a rabbit infected with BoTat-4. The rabbit infected with BoTat-20 from which BoTat-4$^{(20)}$ was isolated, was immunized against VSG-1 to prevent passage through a VSG-1-expressing intermediate. *b*, *Bam*HI restriction profiles of VSG-1-related sequences in the DNAs of various variants. DNA was isolated from each variant, digested with *Bam*HI which does not cut the VSG-1-coding sequence, electrophoresed in a 0.5% agarose gel, blotted to nitrocellulose filters and hybridized to ^{32}P-labelled VSG-1-specific cDNA plasmid pTe 1.6 as described previously[9]. The numbers above the lanes denote the variants from which the DNA was taken. The large (>60 kilobase pair) fragment is present in all of these variants, but is partially degraded in some of the DNA preparations. Molecular weight standards were from a *Bgl*II digest of coliphage T4 DNA and sizes are given in kb.

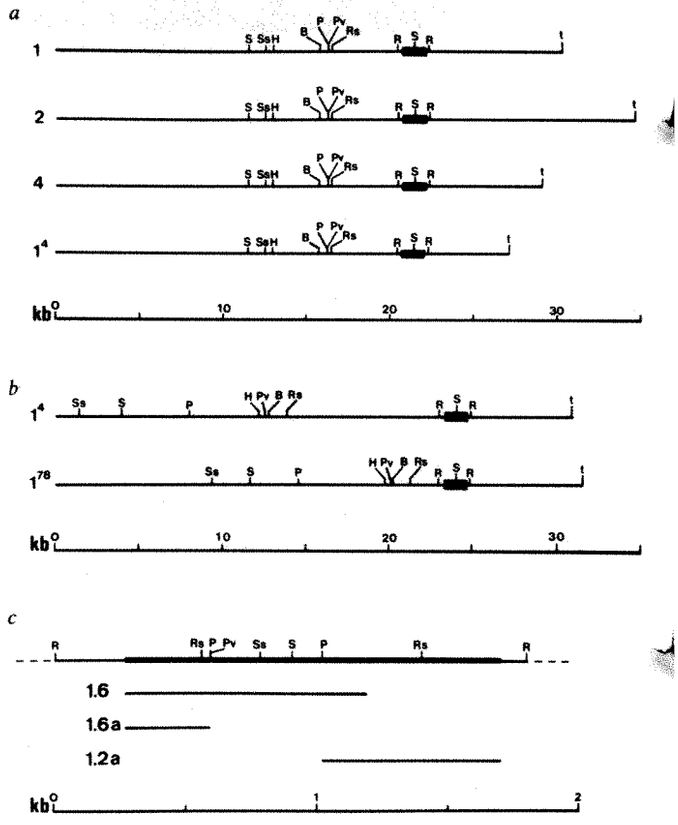

Fig. 2 Restriction maps of DNA containing VSG-1 genes. *a*, Maps of VSG-1 ELC in BoTat-1 and VSG-1 R-ELC in BoTats-2, -4 and -1$^{(4)}$. *b*, Maps of active VSG-1 ELCs in BoTats-1$^{(4)}$ and -1$^{(78)}$. *c*, Map of expanded coding sequence of the VSG-1 gene. The derivations of the various probes have been described previously[9] and are shown beneath the expanded map: 1.6, pTe 1.6; 1.6a, 5′-specific pTe 1.6a; 1.2a, 3′-specific pTe 1.2a. The maps were generated by treating the DNAs with single or multiple restriction endonucleases and hybridizing separately with ^{32}P-labelled 3′- or 5′-specific VSG-1 probes. Sites mapping within the sequences homologous to the VSG-1 cDNA clones (solid boxes) are not shown in *a* or *b* but are given in the expanded map in *c*. Transcription is from left to right. Sites that are 'universally' sensitive to restriction endonucleases and are presumed chromosome telomeres are marked (t). Symbols: S, *Sal*I; Ss, *Sst*I or isoschizomer *Sac*I; H, *Hin*dIII; B, *Bam*HI; P, *Pst*I; Pv, *Pvu*II; Rs, *Rsa*I; R, *Eco*RI.

VSG-1 ELC and BC in BoTat-1[14], the 3′ ends of the VSG-1 R-ELCs were proximal to apparent chromosome telomeres. This was inferred from the presence of 'universal' restriction sites at the presumed chromosome termini in the DNA sequences flanking the 3′ ends of these R-ELCs (see maps in Fig. 3) and from the selective sensitivity of these 3′-specific fragments to *Bal*31 exonuclease (data not shown). The only differences observed in the maps of the original VSG-1 ELC and the R-ELCs were in the lengths of the DNA sequences between the VSG-1-coding sequence and the apparent chromosome telomeres.

To assess the level of activity of the R-ELCs in BoTats-2 and -4, the trypanosomes were screened by immunofluorescence with anti-VSG-1 antibody and their purified RNAs were examined by Northern filter hybridization with VSG-1-specific cDNA probes; no VSG-1 glycoprotein or VSG-1 mRNA was detected (data not shown). Finally, because it was shown recently that chromatin containing the ELC of an expressed VSG gene is selectively sensitive to DNase I[7], we examined the DNase I sensitivity of chromatin containing the VSG-1 R-ELCs in BoTats-2 and -4. Chromatin was isolated from BoTats-1, -2 and -4, treated with DNase I, and analysed as described in Fig. 3 legend. As expected from previous work[9], the 8.6-kb *Sac*I fragment containing the 5′ end of the VSG-1 ELC in BoTat-1 was selectively degraded by the DNase I treatment (Fig. 3*a*). In contrast, the 8.6-kb fragments containing the 5′ end of the VSG-1 R-ELC in BoTat-2 (not shown) and BoTat-4 (Fig. 3*b*) were not selectively sensitive to DNase I. From these results we conclude that the VSG-1 R-ELCs are inactive and that their inactivation was accompanied by alterations of the chromatin containing the gene.

As the VSG-1 ELC was inactivated but not lost on antigenic variation to BoTats-2 and -4, we asked whether it would be reactivated after a change back to VSG-1 expression. Thus, a rabbit was infected with BoTat-4 and the VSG-1-expressing variant BoTat-1$^{(4)}$ was isolated. The hybridization profile of the VSG-1-specific sequences in BoTat-1$^{(4)}$ DNA after cleavage with *Bam*HI is shown in Fig. 1*b*. Clearly, BoTat-1$^{(4)}$ contained two VSG-1-specific sequences not present in BoTats-20, -28

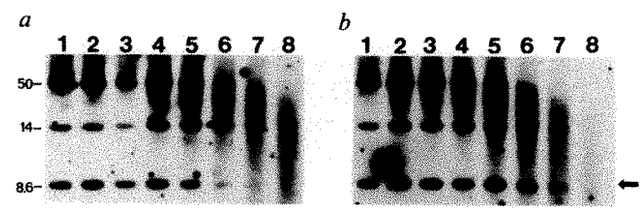

Fig. 3 DNase I-sensitivity of VSG-1 R-ELCs. *a*, DNA from BoTat-1; *b*, DNA from BoTat-4. The procedure for DNase I treatment of trypanosome chromatin has been described in detail elsewhere[7]. Briefly, nuclei were isolated from 2×10^9 trypanosomes and treated at 20 °C with 80 ng ml^{-1} RNase-free DNase I (Worthington Biochemicals). Aliquots were taken at 0 min (lane 1), 0.5 min (lane 2), 1 min (lane 3), 2 min (lane 4), 5 min (lane 5), 10 min (lane 6), 20 min (lane 7) and 40 min (lane 8). The DNA was extracted, treated with *Sac*I, electrophoresed in a 0.6% agarose gel, blotted and hybridized with ^{32}P-labelled 5′-specific cDNA probe pTe 1.6a. The arrow shows the position of the 8.6-kb fragment containing the 5′ end of the VSG-1 ELC in BoTat-1 or the VSG-1 R-ELC in BoTat-4. Sizes of the fragments are in kb.

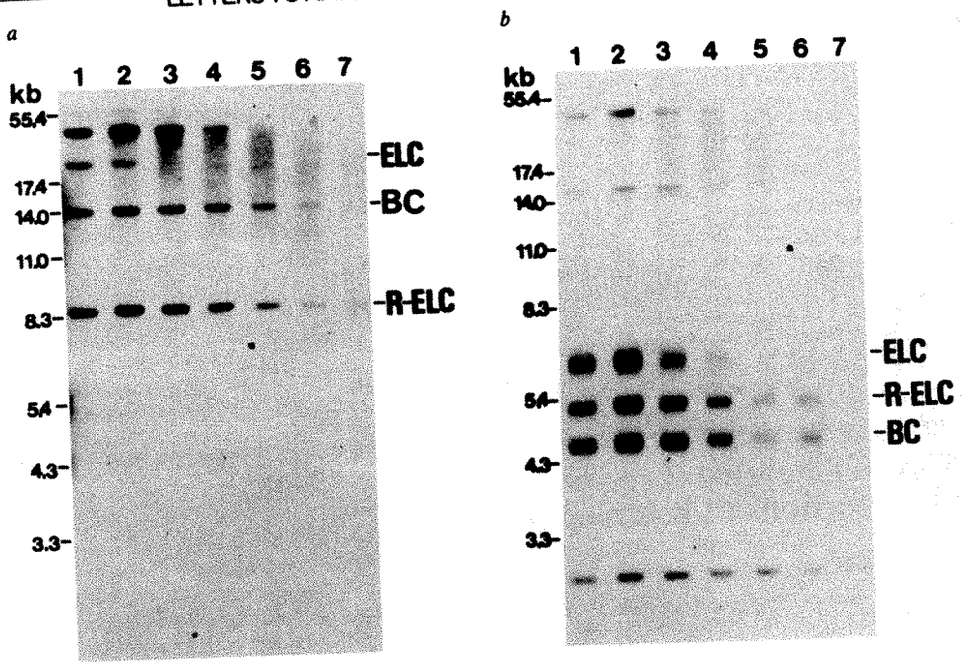

Fig. 4 DNase I-sensitivity of new VSG-1 ELC and R-ELC in BoTat-1(4). *a*, Sensitivity of 5′-specific sequences; *b*, sensitivity of 3′-specific sequences. Nuclei were isolated from BoTat-1(4) and treated with DNase I as described in Fig. 3 legend. Aliquots were taken at 0 min (lane 1), 0.5 min (lane 2), 1 min (lane 3), 2 min (lane 4), 5 min (lane 5), 10 min (lane 6) and 20 min (lane 7). The DNA was extracted, cut with *Sac*I, electrophoresed and blotted as described in Fig. 3 legend. The blot in *a* was hybridized with the 5′-specific VSG-1 probe pTe 1.6a; that in *b* was hybridized with the 3′-specific VSG-1 probe pTe 1.2a. The positions of the fragments containing the 3′ or 5′ ends of the new VSG-1 ELC (ELC), the residual VSG-1 ELC (R-ELC) and the 3′ end of the VSG-1 basic copy (BC) are shown. Molecular weight standards are from a *Bgl*II digest of coliphage T4 DNA.

or -78. Restriction analysis showed that the 5′ genomic environment of one of these VSG-1 copies was identical to that of the BoTat-1 ELC and the VSG-1 R-ELCs in BoTats-2 and -4 (Fig. 2*a*). The DNA flanking the 3′ end of this VSG-1 gene was associated with an apparent chromosome telomere. We conclude, therefore, that this VSG-1 gene represents the VSG-1 R-ELC and that it was not deleted during the processes that produced BoTat-1(4).

The second supplementary VSG-1 sequence in BoTat-1(4) was newly produced in this variant. The 5′ flanking regions of this VSG-1 gene resembled the 5′ flanking region of the previously described VSG-1 ELC in BoTat-1(78) (Fig. 2*b*). However, it contained a 7–8-kb restriction endonuclease-insensitive sequence that is not present in the corresponding region of the BoTat-1(78) ELC. This was not surprising in view of previous reports that the 5′ environments of different ELCs in the same genomic site differ by the presence of variable length DNA sequences that are insensitive to restriction enzymes[9,10,13,19–22]. The 3′ end of the newly produced VSG-1 gene in BoTat-1(4) was again proximal to a chromosome telomere and thus cannot be closely linked to the telomeric VSG-1 R-ELC in this variant.

To determine which of the VSG-1 gene copies in BoTat-1(4) were active, chromatin was isolated and analysed with DNase I as described above. With a 5′-specific VSG-1 cDNA probe, only the 22-kb *Sac*I fragment containing the 5′ end of the newly produced VSG-1 gene was preferentially DNase I-sensitive; the 8.6-kb fragment containing the 5′ end of the VSG-1 R-ELC was stable (Fig. 4*a*). Similar experiments using 3′-specific VSG-1 cDNA plasmid as probe showed that the fragments containing the 3′ ends of the VSG-1 BC and R-ELC were slightly sensitive to DNase I treatment, but that the fragment containing the 3′ end of the new VSG-1 gene was very sensitive to such treatment (Fig. 4*b*). We have shown previously that the telomeric DNA associated with silent VSG genes is slightly sensitive to DNase I treatment[23]. These results suggested that only the new VSG-1 copy in BoTat-1(4) is transcribed. Thus, in BoTat-1(4), the VSG-1 R-ELC was not reactivated and a new, active VSG-1 ELC was created.

Our observations show that the VSG-1 ELC in BoTat-1 was inactivated *in situ* during the antigenic variations which produced BoTats-2, -4 and -1(4). This demonstrates that the simple presence of a VSG-1 ELC in a potential expression site is not sufficient for its expression. The new, active VSG-1 ELC and the inactive R-ELC in BoTat-1(4) were shown to be linked to different chromosome telomeres. Similary, the ELCs of the VSG-2 and VSG-4 genes were not closely linked to the VSG-1 R-ELCs in BoTats-2 and -4 (unpublished data). These results reinforce our previous assertion that there are multiple telomeric sites which can accept VSG-1 ELCs.

Overall, our results with *T. equiperdum* argue that VSG genes are activated by duplication and transposition into one of several telomeric acceptor sites which are subject to secondary control mechanisms. Thus a VSG gene could be activated either by direct replacement of the previously active ELC or by transposition into an inactive acceptor site which can subsequently be activated. This model explains how some VSG genes are apparently activated by a simple duplicative transposition (direct replacement of an active ELC) and how other VSG genes are activated without obvious duplication (activation of an inactive acceptor site containing a previously duplicated VSG gene). Loss of an ELC, as observed for the VSG-1 ELC after variation from BoTat-1 to BoTats-20, -28 and -78, would occur by its replacement in the acceptor site with a newly duplicated VSG gene copy. Conclusions similar to these have been reached by Young *et al.*[24].

The mechanisms which activate the duplicated VSG genes in the various acceptor sites are not yet understood. Translocation of a VSG gene in an acceptor site to a position *cis* to an 'expression element' via a reciprocal recombination 10–30 kb upstream from the VSG gene would explain our observations of multiple acceptor sites and the maintenance of the VSG-1 R-ELCs. Similarly, an 'expression element' could be recombined into a position 3′ to the VSG gene-containing acceptor site. Other mechanisms such as DNA modification or a system of repressors and inducers are also possible factors controlling VSG genes in a finite number of telomeric acceptor sites.

We thank Dr Charles Roth for careful reading of this manuscript. This work was supported by grants from the CNRS and the Institut National de la Santé et de la Recherche Medicale. G.A.B. received support from NIH grant AI06661.

Three-dimensional reconstruction from tilted sections of fish muscle M-band

P. K. Luther

Biophysics Section, Physics Department, Imperial College, London SW7 2BZ, UK

MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

Fish muscle provides a particularly suitable specimen for studying the organization of thick filaments in vertebrate striated muscle because the filaments are arranged with a single orientation on a well ordered hexagonal lattice[1]. The M-band consists of sets of cross-links, which join the myosin filaments in the middle of the A-band. Previous work[1] concluded that the fish muscle M-band had the local symmetry of the dihedral point group *32*. We present here a quantitative analysis of transverse sections of the M-band, using general methods[2] developed for crystalline layers, to combine various tilted views. The three-dimensional map computed to a resolution of about 70 Å confirms previous findings[1]; it shows new features of the thick filament structure in the M-band region and provides new information on the use of three-dimensional reconstruction from sectioned biological material. The accompanying paper[3] describes a novel technique of three-dimensional reconstruction of the fish M-band from a single view of a slightly oblique plastic section.

In fish muscle the thick filaments are arranged in rotational register[1], making the M-band crystalline. There are three main axial levels of M-bridges within this M-band[4]: M1 in the middle, with M4 and M4′ about 220 Å on either side (Fig. 1). The bands at M6 and M6′, about 220 Å outside M4 and M4′, are very weak in the plaice fin muscle studied here. From a study[1] of very thin slightly oblique transverse sections, three distinct structures were identified, which were thought to be associated with the M1, M4 and M6 bands seen in longitudinal sections (Fig. 1). At M1 there were straight M-bridges while at M4 and M4′ the thick filament backbone comprised three subunits with bean-shaped M-bridges. The structure showed a clear hand which reversed from M4 to M4′ and the symmetry of the M-band corresponded to the dihedral point group *32*.

The micrograph in Fig. 2 shows an example of an M-band cross-section used for three-dimensional reconstruction. The thick filament spacing was about 350 Å and this value was used throughout, although the value in the native muscle would be somewhat larger. The section, estimated as about 600 Å thick from the interference colour during microtomy, should include the whole of a centrally located M-band from M4 to M4′ (440 Å). Micrographs were taken at tilt angles from −60° to +60° in steps of 5° about two mutually perpendicular axes. The total exposure was consequently large but it appeared that the section was relatively stable after the initial high dose exposure.

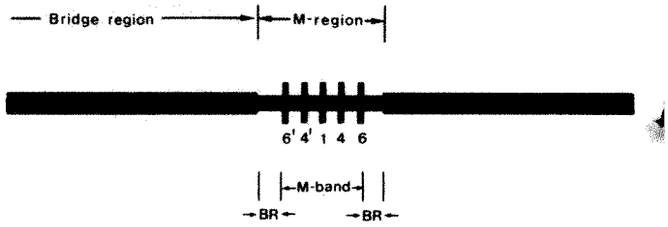

Fig. 1 Schematic drawing of part of a thick filament showing details of the myosin crossbridge-free M-region as it is seen in longitudinal sections of the A-band[4]. The M-region comprises the M-band and the bare region (BR). The three main levels of M-bridges in the M-band are M1 in the middle with the M4′ and M4 bridges about 220 Å to either side. Additional density is seen in some muscles at M6 and M6′, about 220 Å outside M4 and M4′.

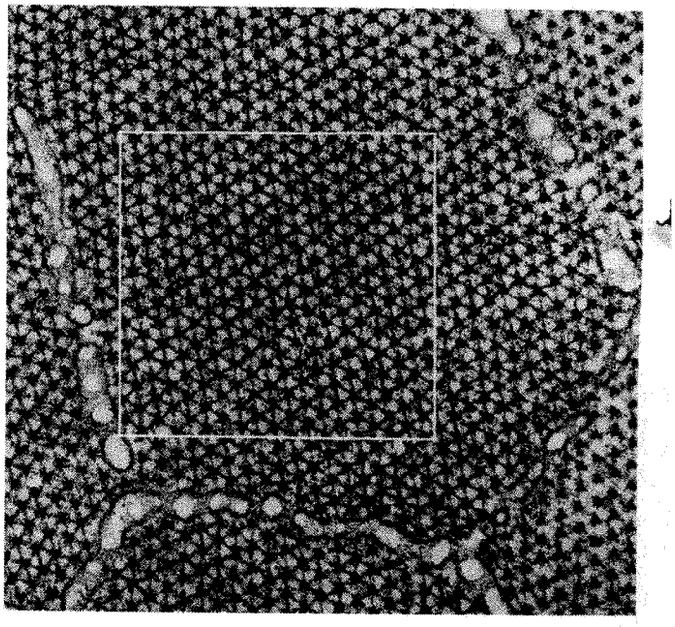

Fig. 2 Transverse section of the plaice fin muscle M-band (×80,000). The boxed area was used for reconstruction. The muscle was processed and embedded in Araldite as described previously[1]. Transverse sections of silver-grey interference colour were cut with a diamond knife which, from past experience using section folds, corresponds to a thickness of about 600 Å. The sections were stained with uranyl acetate and Reynolds lead citrate. For electron microscopy, a JEOL 200CX fitted with a rotation goniometer was used. Micrographs at a magnification of ×20,000, were obtained by tilting the section in steps of 5° from −60° to +60°, covering the low tilt angles first in order to stabilise the section. The section was then rotated by 90° and another tilt series obtained. The best areas were selected by optical diffraction.

Fourier transforms were computed of each view and a three-dimensional set of data was constructed using standard programs[2], assuming minimal P1 symmetry in the specimen. Figure 3 shows data for some of the stronger lattice lines. The transform of the untilted view showed strong 3-fold rotational symmetry when the appropriate phase origin was found on the thick filament, although the lattice was distorted by compression of about 10% in the direction of sectioning. The three-dimensional reconstruction computed with no assumption about symmetry also showed a similarly striking 3-fold rotation axis, though again with compression of the lattice. After correcting for the compression, the data were therefore 3-fold averaged and a further reconstruction computed. It is this 3-fold averaged map which will be described.

The computed thickness of the section in the reconstruction was only about 300 Å, a value much lower than the initial

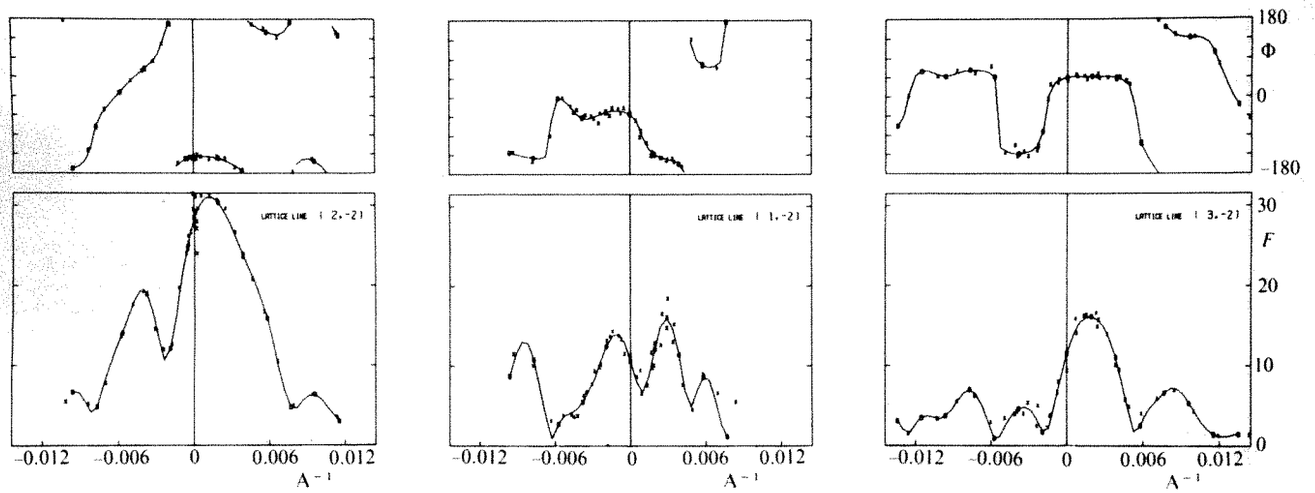

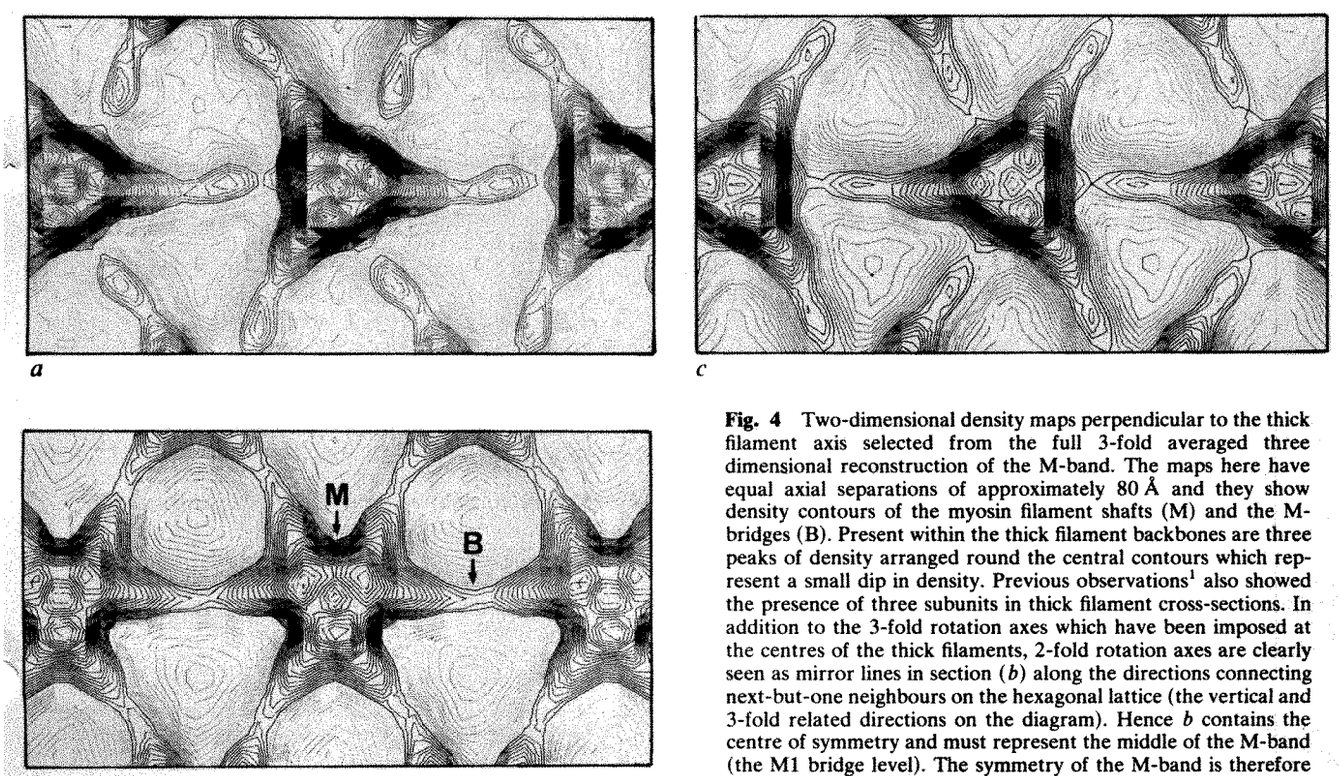

Fig. 3 Plots of observed Fourier transform data along three of the stronger lattice lines. In each pair of plots the lower one represents the amplitude and the upper one the phase. Observed points are plotted as crosses (×) and the equally spaced points interpolated by computer are plotted as circles (○) with continuous curves drawn between them.

thickness of about 600 Å estimated from the interference colour. This suggests that the section has shrunk considerably in the electron beam. Shrinkage of plastic sections during electron microscopy has been noted before[5,6] and a detailed study[6] showed that Araldite sections reduced in thickness by about 50%. Shrinkage of the M-band sections would result in the closing up of the M-bridge levels. A comparison of features common to the reconstruction from the oblique section[3] with this map also suggests a shrinkage to 50% of the true value.

The final three-dimensional reconstruction was built up from two-dimensional density maps computed at axial spacings of 20 Å nominal, which would correspond to about 40 Å in the original muscle. One such map (Fig. 4*b*) not located at the centre of the reconstruction, contains clear 2-fold rotation axes seen as mirror lines along directions of the hexagonal lattice connecting next-but-one neighbouring thick filaments. The bipolar nature of the thick filament[7] implies that this represents the centre of the M-band (that is, the M1 bridge level). Examples of maps at equal separations (about 80 Å in the muscle) on either side of the M1 plane are shown in Fig. 4*a* and *c*. The same 2-fold symmetry relating these maps (and others not shown) is striking; there can be little doubt that the local symmetry of the M-band is described by the dihedral point group *32*, and that the layer as a whole has space group P*321*.

Figure 5 shows two stereo pairs of the M-band reconstruction viewed from opposite sides. The M-band was not centrally located in the plastic section, and M1 lies deep in the model viewed as in Fig. 5*a* with M4 and the M6 region above it. In

a *c* *b*

Fig. 4 Two-dimensional density maps perpendicular to the thick filament axis selected from the full 3-fold averaged three dimensional reconstruction of the M-band. The maps here have equal axial separations of approximately 80 Å and they show density contours of the myosin filament shafts (M) and the M-bridges (B). Present within the thick filament backbones are three peaks of density arranged round the central contours which represent a small dip in density. Previous observations[1] also showed the presence of three subunits in thick filament cross-sections. In addition to the 3-fold rotation axes which have been imposed at the centres of the thick filaments, 2-fold rotation axes are clearly seen as mirror lines in section (*b*) along the directions connecting next-but-one neighbours on the hexagonal lattice (the vertical and 3-fold related directions on the diagram). Hence *b* contains the centre of symmetry and must represent the middle of the M-band (the M1 bridge level). The symmetry of the M-band is therefore that of the dihedral point group *32* as noted previously[1]. (Note that the density map in *b* was not located at the middle of the plastic section or of the three-dimensional reconstruction.)

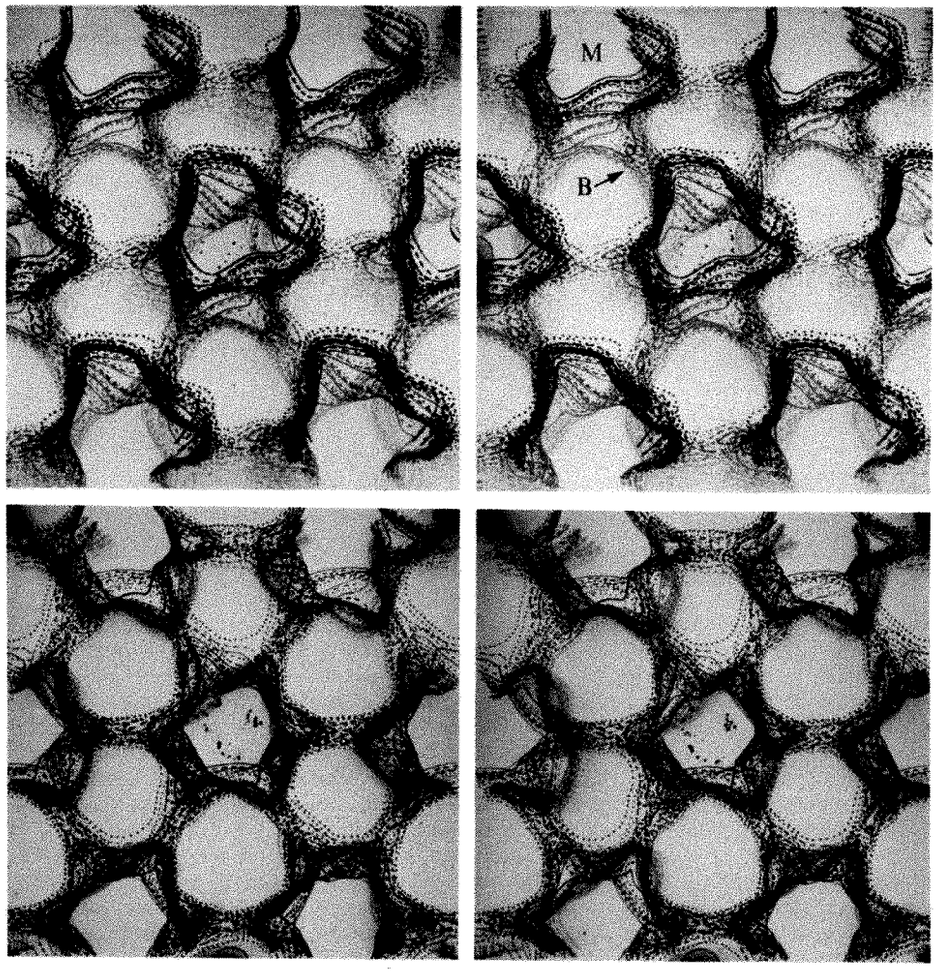

Fig. 5 Two stereo pairs of a Perspex model of the full three-dimensional reconstruction of the M-band viewed from 'above' (*a*) and 'below' (*b*). For clarity only three contour levels are shown. The dotted lines represent the lowest density, and the dashed and continuous lines represent respectively higher densities. Located in the centre of the images is a myosin thick filament (M). The lower part of the stereo view *a* shows the M-bridges (B) emanating from the thick filaments while the upper part shows the M6 region. The three points marked in the core of the central thick filament represent peaks of density. In *b* the peaks are seen to spiral through the M-band in an anticlockwise fashion viewed from the centre of the M-band. The stereo views clearly show 2-fold rotation axes in the M1 plane through next nearest thick filaments.

the opposite view shown in Fig. 5*b* M4′ lies at the top surface. The *32* symmetry of the M-band is clear in both stereo pairs. In Fig. 5*b*, three dots marked in the core of the central thick filament represent peaks of density and their mean separation is about 75 Å relative to the 350 Å filament spacing. The peaks spiral through the M-band in an anticlockwise manner as viewed from the centre of the M-band. However, at the low resolution of the reconstruction, this spiralling is also consistent with parallel rods of density overlapping at M1 as suggested earlier[1]. The hand of the whole M-band structure was confirmed independently using serial sections.

The outer profile of the thick filament is strongly modulated, giving the effect of ridges running along the filament. There are two sets of three ridges, one set on each side of the M1 level. The two sets are azimuthally out of register and overlap at the M1 level, giving the profile there a strongly six-lobed appearance (Fig. 4*b*). Moving from M1, one or other set quickly terminates, producing an overall triangular shape (Fig. 4*a*, *c*). These ridges run with a slight twist right up through the M6 region (Fig. 5*a*) and appear to terminate there[3]. The M-bridge density links to these ridges. It is not clear at this resolution whether to ascribe the density in the ridges to myosin tails, to M-bridges, to other M-band proteins or to some combination of these.

The three-dimensional reconstruction shows M-bridge density clearly but does not resolve the different axial levels of the M-band expected from the M-bridge stripes seen in longitudinal sections (Fig. 1). This may be because the plane of sectioning was not exactly transverse or may have wandered. Also the M-band itself may not have been exactly planar, since examination of longitudinal sections shows that the M-band may be slightly curved within a myofibril. These effects would lead to axial smearing of the M-bridge density and consequent lack of axial resolution. Additionally, shrinkage normal to the section must close up the three M-bridge levels and make them less easy to resolve. A study of the shrinkage behaviour of plastic sections in the electron microscope is under way and the results will be reported elsewhere.

The application of three-dimensional reconstruction methods to plastic sections has produced a more quantitative and objective picture of the M-band than was previously available. The fish muscle M-band is established to have *32* symmetry and it is likely the thick filament as a whole has the same symmetry. Despite the factors limiting the resolution of the M-bridges, the axial details in the thick filaments are displayed more clearly here than could be seen directly, even in the ultrathin (200 Å) sections used previously[1]. Further interpretation of the M-band must depend on specific labelling techniques. However, taken in conjunction with results from oblique reconstruction[3], these maps provide constraints which future models of the M-band must satisfy.

We thank Dr John Squire for helpful discussions. The electron microscopy was carried out in the Biophysics Department, King's College, London. This work was supported by the MRC.

Three-dimensional reconstruction from a single oblique section of fish muscle M-band

R. A. Crowther

MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

P. K. Luther

Biophysics Section, Physics Department, Imperial College, London SW7 2BZ, UK

A new method of three-dimensional image reconstruction from electron micrographs is presented here, which enables a three-dimensional image to be produced from a single oblique section of a two- or three-dimensional crystal. The method, which is most powerful when the section is thin and the angle of obliquity small, has several potential advantages over the conventional method of reconstruction[1] using tilted views of the section. In particular the accumulated electron dose on the specimen is much smaller and the reconstruction is not affected by changes in the thickness of the section during exposure to the electron beam. The method involves the solution of a generally almost singular set of linear projection equations[2], relating through the sectioning geometry the three-dimensional crystal density to the two-dimensional projected image density. This can be achieved most conveniently by linear least squares filtering[3]. An application of the method to determine the structure of the M-band of fish muscle is described. The resulting map agrees well with that produced by the more conventional approach involving tilted views[4].

It is easiest both to visualize and to apply the method when the crystal is two-dimensional and when the direction of maximum slope of the section is normal to one of the cell edges of the crystal. Accordingly it is that situation which will be described and used here, although there should be no difficulty in working with a general oblique section of a three-dimensional crystal, except that the computation would be more complicated. With the above assumptions, the section contains rows of equivalent unit cells of the crystal (Fig. 1*a*), which can be averaged normal to the direction of maximum slope to give a 'strip image' one cell wide (Fig. 1*b*). Each cell of the strip image gives a projected superposition of a different set of levels from the full unit cell of the crystal (Fig. 2). As a consequence of the restrictive assumptions made about the sectioning geometry, the two-dimensional problem has been factorized, allowing one-dimensional averaging to give an improved signal-to-noise ratio in the strip image, followed by a simple one-dimensional reconstruction. For a general sectioning geometry this factorization would not be possible and the averaging and reconstruction could not be so separated.

The matrix of coefficients P_{ij} of the projection equations, $\sigma_i = \sum_j P_{ij}\rho_j$, (see Fig. 2) depends on the geometry of the crystal and of the section. In particular it depends on the rise per cell of the section and its thickness and these parameters must be known before the equations can be set up and solved. A choice must also be made of the pixel thickness and of the overall thickness of the specimen to be reconstructed. In general the projection equations comprise a rectangular set, with more observations σ_i than unknowns ρ_j, so that the system is most easily solved by least squares. It is nevertheless likely that the equations will be poorly conditioned, in that certain combinations of pixel weights ρ_j will be represented hardly at all in the projection data σ_i and will not therefore be recoverable without unacceptable noise amplification, as has been previously discussed for reconstruction from tilted views[2,5]. It is therefore necessary to solve the projection equations by a least-squares filtering procedure[3], in which only the best determined combinations of pixel weights ρ_j are recovered. This can be achieved by computing the eigensystem of the normal equations and recovering only those eigenvectors with eigenvalue λ such that λ/λ_{max} is greater than some specified filter level. The choice of filter level depends on the noise in the data and here a value of 0.01 was found to be appropriate.

For the M-band the sectioning geometry relative to the native muscle can be established approximately by inspection of the micrograph, since the separation of M9–M9′ along the thick

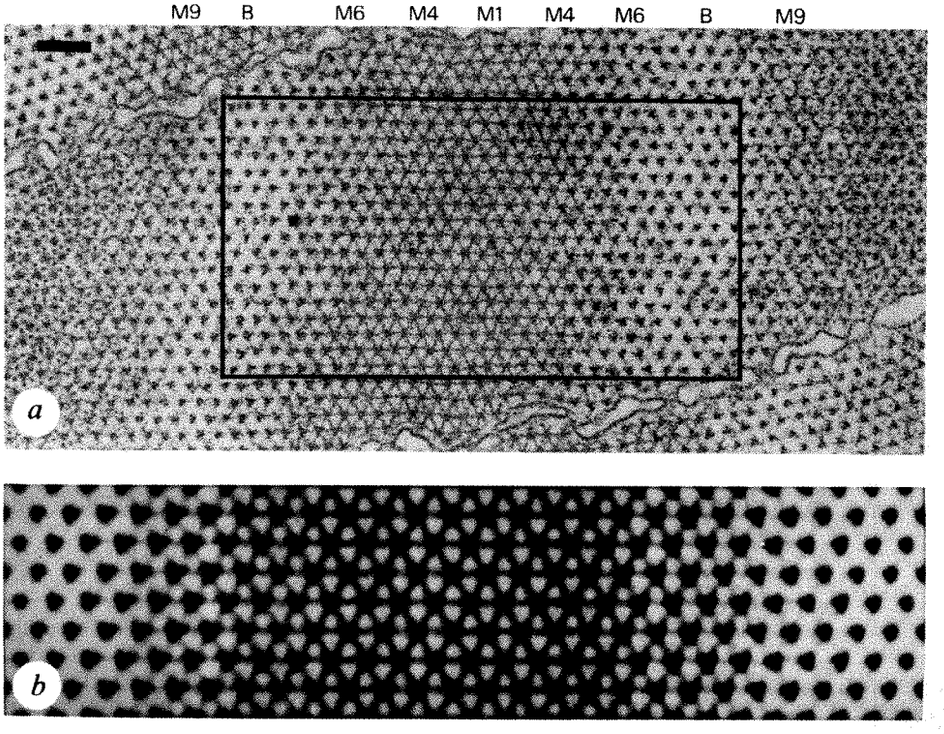

Fig. 1 *a*, Electron micrograph of a thin oblique, though approximately transverse, section of roach muscle M-band, prepared as described in ref. 7. The positively stained protein appears black and the thick filament profiles form an approximately hexagonal lattice. The direction of maximum slope lies left–right so that starting from the centre of the image one sees in both directions successively the M1, M4, M6, bare (B) and M9 regions of the M-band[6]. Scale bar, 100 nm. *b*, Strip image formed by one-dimensional averaging of the boxed area in *a*, normal to the direction of slope of the oblique section. The averaging by computer is performed directly on the image density, using bilinear interpolation[9] to correct for small distortions in the thick filament lattice and correlation to get the best alignment of rows of unit cells before averaging. The result is a strip image one cell wide, which has here been extended by repetition to an area four cells wide, so that the pattern can be more clearly seen. The strip image is sampled every 2.2 nm at equivalent points within each cell, so simplifying the subsequent reconstruction. The distorted hexagonal lattice of thick filament profiles is thus made perfectly hexagonal and is represented most conveniently in the computer by a centred rectangular cell of size $a \times \sqrt{3}a$, where $a = 35$ nm is the mean separation of thick filaments. Every rectangular cell therefore has a thick filament at each corner and one in the centre. The features around each thick filament profile show 3-fold symmetry and the strip image as a whole has a vertical mirror plane at its centre.

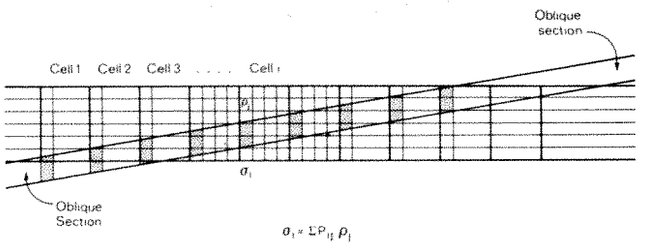

Fig. 2 Geometry of oblique sectioning of a two-dimensional crystalline layer one unit cell thick. If it is assumed that the direction of maximum slope is normal to one of the cell edges, then the description of the geometry is simplified (see text). Each unit cell is considered to be divided up into a three-dimensional array of pixels of density ρ_j. The oblique section then cuts out a gradually changing set of pixels from equivalent columns of density in the various unit cells, as indicated by the stippled areas. When the oblique section is viewed in the electron microscope the resulting image will represent the projected densities σ_i, corresponding to summing the subsets of pixels cut out by the section. The unknown densities ρ_j in the specimen are thus related to the measured density values σ_i by linear projection equations of the form $\sigma_i = \sum_j P_{ij}\rho_{ij}$, where $P_{ij} = 0$ if pixel ρ_j does not lie within the section in column i, $P_{ij} = 1$ if it does and P_{ij} will be a positive fraction if the pixel lies across the bounding surface of the section. For the simplified geometry considered, the σ_i will arise from equivalent points in each cell of the strip image and the different columns of density through the specimen can be reconstructed independently of each other. There will be one set of projection equations for each set of equivalent columns of density. Strictly speaking the oblique section ought to be tilted in the microscope to an angle equal to the sectioning angle before taking the picture. However, for small sectioning angles and thin sections the effect is not important, as can be seen in the strip image in Fig. 1*b* in which the thick filament profiles show no discernible elongation in the sectioning area.

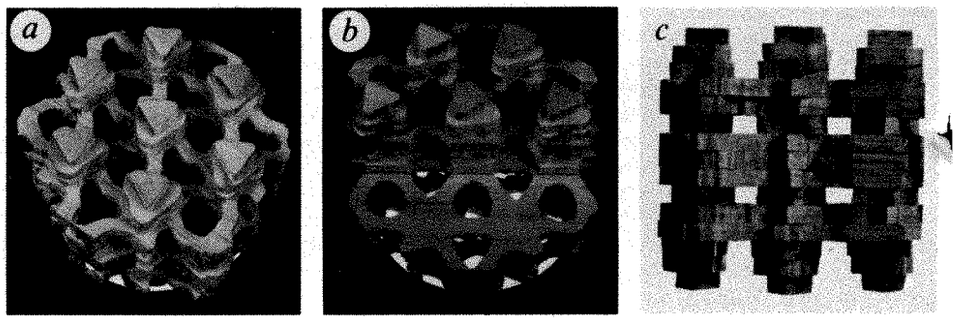

Fig. 3 A balsa wood model of the averaged reconstruction made from the strip image in Fig. 1*b*. Each section represents 6 nm and a total thickness of 90 nm is shown. *a*, The whole model consisting of a central thick filament surrounded by its six nearest neighbours. *b*, One-quarter of the model has been cut away to show the internal details. *c*, A side view along the direction of the hexagonal cell edge in which the filaments overlap. The 2-fold axis normal to the thick filament lies in the section revealed in the cut-away map *b*, which can be seen to have mirror lines through next nearest filaments. The absolute hand of the structure cannot be established from a single oblique section, so the handedness of the model was chosen to agree with that established for the reconstruction from tilted views[4].

filament is known[6] to be about 138 nm and in the oblique section (Fig. 1*a*) this rise takes place in about 38 thick filament spacings. Thus the section rise per filament or per unit cell in the strip image (Fig. 1*b*) is about 3.6 nm. The bare region between M6 and M9 is clearly visible but would not be seen if the section were thicker than about 30 nm. With these values of rise per cell and thickness, features should persist in the strip image for about six or seven cells, which appears to be the case here. The values of rise per cell and section thickness can be refined by setting up and solving the projection equations for a range of different values of the two parameters and taking those that give the smallest least squares residual as the best estimates. In this case the best values of rise per cell and section thickness were 3.62 nm and 27 nm respectively. This corresponds to a section angle of 5.9° to the strictly transverse for a thick filament spacing of 35 nm. A pixel depth of 6 nm was used and a total thickness of 102 nm reconstructed, giving 17 levels in all. However, only 12 of the 17 possible eigenfunctions satisfied the recoverability criterion $\lambda/\lambda_{max} > 0.01$ (see above), giving an effective independent pixel depth in the reconstruction of $102/12 = 8.5$ nm. This is rather less than one-third of the section thickness, so that the reconstruction procedure has produced a map with markedly better depth discrimination than can be obtained simply by looking at the strip image.

The M-band has been shown[4,7] to have *32* symmetry and it is clear that the strip image (Fig. 1*b*) has an overall vertical mirror plane at its centre and that the features around each thick filament profile are strongly 3-fold related. The map produced by the reconstruction procedures was therefore 3-fold and 2-fold averaged along appropriate directions to improve its signal-to-noise ratio. A model of this averaged map is shown in Fig. 3.

The reconstruction shows that the thick filaments are connected by strong fairly straight bridges (M1) at the centre of the M-band. About 22 nm away on either side the filaments are connected by curved bridges (M4, M4'). The thick filaments have a rather uniform diameter throughout the M-region but become much thinner about 40 nm from the centre of the M-band as is also clearly seen in the strip image (Fig. 1*b*). This appearance could be due to ridges of extra material running along the thick filament, giving the filaments a strongly three-lobed cross-section throughout the M4–M6 region. These ridges may well be formed partly or wholly by myomesin, which seems to run throughout the central M-region but which probably does not contribute to the M1 or M4 bridges[8]. The curved bridges at M4, which may be formed by creatine kinase[8], appear to start and end on these ridges.

The features seen in this oblique reconstruction agree well with those seen in the reconstruction from tilted views[4]. In particular, the shapes of the holes outlined by the thick filaments and M-bridges vary from section to section in the same way in the two maps. The principal differences are that in the oblique reconstruction the M4 bridges are more clearly visualized and the spacings along the filament direction are not affected by section collapse, because the computed geometry of the section is based on spacings close to those of the native muscle. Thus although this method of oblique reconstruction is intrinsically less powerful than that based on tilted views, it does nevertheless have some advantages and certainly gives improved depth discrimination compared with that obtained by direct viewing of oblique sections.

IUPHAR 9TH INTERNATIONAL CONGRESS OF PHARMACOLOGY

29 JULY – 3 AUGUST 1984

LOCATION

Barbican Centre for Arts and Conferences, City of London

SCIENTIFIC PROGRAMME

The scientific programme will extend over five days and consist of symposia, invited lectures, pharmacological debates, an educational meeting and free communications, the latter as both oral and poster sessions. The symposia will consist of three simultaneous sessions morning and afternoon and each day there will be four invited lectures. A new feature of the International Conference is the pharmacological debates. In these the intention is to select topics on which there are clear differences in evidence or its interpretation and have the issue debated between protagonists of each view with sufficient opportunity for the audience to participate. In the educational meeting it is hoped to concentrate on the place of various forms of programmed learning in Pharmacology and the instrumentation available. Finally, there will be free communications and to the fullest extent possible authors will be allowed to select whether to give these as oral communications or as a poster.

PROCEEDINGS

The Congress Proceedings are being published by Macmillan Press and may be ordered in advance of the registration form or at the Congress.

SOCIAL EVENTS

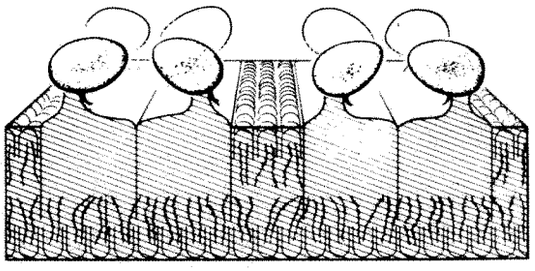
A full social programme is being arranged for delegates and accompanying guests. Details are given in the advance programme.

ACCOMMODATION

Accommodation has been reserved at advantageous rates in a number of hotels in various price categories and in student halls of residence. All accommodation is within easy travelling distance of the Barbican Centre.

DATES TO REMEMBER

31 January 1984	Deadline for receipt of abstracts for both invited papers and free communications.
1 May 1984	Deadline for college accommodation reservations.
18 May 1984	Deadline for receipt of registration at the standard fee (£150). There is a late fee after this date of a further £40. Deadline for receipt of papers for Proceedings volumes.



CONGRESS SECRETARIAT

Advance programmes, registration forms and abstract forms can be obtained from the Congress Secretariat:–

Congress Associates ICP
34 Stanford Road
London W8 5PZ
Telephone: 01 937 3163

Attention all biophysicists, molecular biologists and biochemists!

Biomembrane Structure and Function

Edited by
DENNIS CHAPMAN
Professor of Biophysical Chemistry
Royal Free Hospital
School of Medicine, London

Volume 4 in the TOPICS IN MOLECULAR AND STRUCTURAL BIOLOGY Series
Series editors:
Professor Watson Fuller, Dr Stephen Neidle and Professor Tony Atkinson

The application of physical techniques – such as X-ray diffraction and Raman spectroscopy – has revolutionised much of our thinking on the structure and function of membranes. In this important new study, contributors of international standing review a topical selection of approaches to the elucidation of **biomembrane structure and function.** The emphasis, throughout, is on the in-depth analysis of recent experimental work.

Published January 1984 Price £50.00 432pp
ISBN 0 333 31869 2

Contents

Calorimetric studies of model and natural biomembranes – *Diana Bach,* The Weizman Institute of Science, Israel; X-ray diffraction and electron microscope studies of the molecular structure of biological membranes – *Lee Makowski and Jade Li,* Columbia University, USA; Raman spectroscopy of lipids and biomembranes – *Surendra P. Verma and Donald F.H. Wallach,* Tufts-New England Medical Centre, USA; Infrared spectroscopic studies of model and natural biomembranes – *Ralph L. Amey,* Occidental College, USA and *Dennis Chapman*; Rotational and lateral diffusion of membrane proteins as determined by laser techniques – *Winfried Hoffman,* NUKEM GmbH, E.Germany, and *Colin J. Restall,* Royal Free Hospital, London; Theoretical models of monolayers, bilayers and biological membranes – *David A. Pink,* St Francis Xavier University, Canada; The Ca^{2+} dependent ATPase of sarcoplasmic reticulum – *G. Inesi and M. Kurzmack,* University of Maryland, USA.

Methods of Seawater Analysis

Edited by (the late) K. Grasshoff, M. Ehrhardt, K. Kremling

Second, revised and extended edition 1983. Hardcover. XXVIII, 419 pages with 108 figures and 26 tables. DM 140,–. ISBN 3-527-25998-8

This second edition of a most successful book includes several new procedures: the use of capillary gas chromatography for the analysis and quantification of chlorinated hydrocarbons, the use of macroreticular resins for concentrating dissolved organic material from large volumes of seawater, and the use of HPLC for amino acid and carbohydrate determinations.

Electrophoresis

Official Journal of the International Electrophoresis Society

1984. Volume 5. Published bimonthly. Annual subscription rate DM 208,– plus postage and handling fee.

Electrophoresis is the name of an international journal that provides a unique forum for the publication of contributions that are meant to catch the attention of those engaged in the development and use of electrophoretic methods.

Electrophoresis publishes original papers, short communications and review articles. Research reports are written with particular emphasis on advanced methods of electrophoresis. Topics include new and improved analytical and preparative methods and theoretical aspects. Other features include book reviews, important conference dates and miscellaneous information.

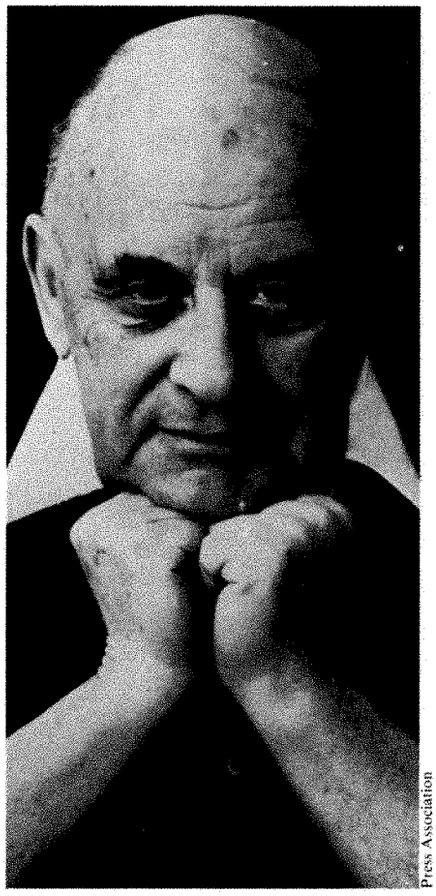
Customers and contractors

Philip Gummett



Government and Research: The Rothschild Experiment in a Government Department. By Maurice Kogan and Mary Henkel.
Heinemann Educational: 1983. Pp.196. £18.50, $37.50.

THE Rothschild Report of 1971 presaged one of the biggest shake-ups ever administered to the organization of science in Britain. It may in time be seen as the high point of the sectoral (or departmentally centred) approach to British science policy, especially if the Government adopts the reforms proposed by Sir Ronald Mason* in November 1983; these would strengthen the Advisory Board for the Research Councils and require all government research (civil and defence) to be included in the debate over the Science Budget of the Department of Education and Science, thus increasing central coordination.

Under Rothschild, government departments were to assume greater responsibility for formulating policy for applied research, which would then be implemented by their contractors. These might be in in-house research establishments, research councils, or elsewhere. By the same token, these contractors were to lose control over their applied research programmes, a particularly painful blow for the three bodies involved, namely, the Agricultural (ARC), Medical (MRC) and Natural Environment (NERC) Research Councils. The implications of the new regime were, however, greater in some departments than others, being modelled on the then current practice of the Ministry of Defence, and not involving much change in organizational reforms already in train at the Department of Trade and Industry.

The only attempt so far at overall evaluation of these reforms has been the one conducted by the government itself (*Review of the Framework for Government Research and Development (Cmnd 5046);* HMSO, 1979, Cmnd 7499); not surprisingly, it was short on analysis though useful as a summary of organizational developments. Kogan and Henkel's book, in contrast, is a detailed, thoroughly researched and methodologically path-breaking examination of how one part of the science–government system, the Department of Health and Social Security (DHSS) and the MRC, responded to Rothschild.

From 1974 the senior author worked as a consultant to DHSS on the operation of the post-Rothschild research management system. He and his research team enjoyed access to internal papers, attended over 200 departmental meetings, conducted over 200 interviews with key individuals and accompanied the Chief Scientist on some of his visits to external research units. The initiative of the DHSS in thus engaging Professor Kogan, and the encouragement given to him to publish, are to be applauded. The high quality of the work should encourage more departments to engage researchers in "on-line" evaluation of organizational reforms and, in an ideal world, it would also mark the end of bland official reviews like Cmnd 7499.

Press Association

Lord Rothschild — the report of 1971 "presaged one of the biggest shake-ups ever administered to the organization of science in Britain".

The price for this exceptional degree of access might well have been a story lacking in colour. And, indeed, most of the characters are not fully identified. But in general this does not matter: it is usually enough to know that we are dealing with an under-secretary in a policy division, or a member of the Chief Medical Officer's staff. Thanks, however, to the encouragement of Professor Arthur Buller, we do learn a lot about his own role when Chief Scientist at the DHSS, and this is all the more creditable because the authors make plain their disagreement with his view of science and its relationship with policy. We learn, for example, that he was less interested in cultivating the system for enunciating biomedical research policy (and thereby maintaining control over the funds transferred from the MRC) than in raising the quality of health services research (p.73); and that on his appointment in 1978 he determined to build up the scientific strength of the Department's research base, in part by strengthening the role of his own office in the commissioning of research at the expense of other parts of the machinery in which policymakers from DHSS divisions took the lead (p.86).

One cannot help wondering, though, what else could be said about how, in 1981, the MRC recaptured the funds lost to DHSS in 1972. For example, in addition to the point made above about the Chief Scientist's priorities, we also read, on p.73, that the MRC, in contrast to the Social Science Research Council (with which the Department also dealt), "enjoyed the confidence of a single, and supremely self-confident, profession strongly represented within" the DHSS. This sentence clearly alludes, in conformity with a theme well-documented in the book, to the institutional power of the biomedical research community and to its ability to impose its view that scientific development should be driven more by the internal norms of science than by social considerations. But does it also allude to the role of the Chief Medical Officer and his staff? One recalls here Sir Alec Merrison's tentative reference, before the House of Lords Select Committee on Science and Technology in April 1981, to the problems of fitting a Chief Scientist into a department which already had a powerful Chief Medical Officer. The role of the politicians in the DHSS is also largely passed over: it is unclear how far the attempt made from 1979 to cut spending on DHSS-funded research units derived from the political level (there being a General Election that year); and, again with reference to the recapture by the MRC of the transferred funds, what precisely lay behind the observation that MRC scientists "knew that they could beat the bureaucrats by appeals to the political system above their heads" (p.75)?

One other cavil: the organizational arrangements within the DHSS were extremely complex and perhaps required more careful description. In particular, the Research Liaison Groups (committees which brought together the policy divisions and scientific advisers to work out research programmes for specific policy areas) are introduced on p.12 as though they covered all aspects of the Department's work; on the next page we learn that many areas were

*Advisory Board for the Research Councils, *A Study of Commissioned Research: Report by Sir Ronald Mason.* Available from the Department of Education and Science, London.

not covered; only on p.77 are we told which areas were covered, having in passing (p.59) learnt that the rationale underlying these committees was to stimulate important but under-researched zones of action. It is clear enough when pieced together, but the task could have been easier.

These are trivial reservations, however, in comparison with the authors' achievements. For the book is not only a detailed review of post-Rothschild developments in the DHSS — a notable feat in itself, if one of limited appeal. It is also an original exercise in the combination of the approaches of the sociology of science and of public administration to the study of science policy. As such, it is a rich quarry of ideas on how to conduct such studies, and on the sheer complexity of the subject. It should be read not only by academic students of science policy and public administration, but by all who are concerned, in whatever way, with relations between science and government.

The book examines theoretically the extent to which science is steerable, or, in a different metaphor, permeable by social values. Drawing on the "finalization" school of sociology of science, the authors distinguish between different phases in the development of disciplines, arguing that disciplines are more steerable (though in different ways) when in the pre- and post-paradigmatic phases, but that in between, where work is beginning to crystallize around key theoretical models, the research programme is much more dictated by "internal" needs and is less susceptible to outside influence. They show how epistemological ideas must be linked with analyses of the institutional power of different sciences (contrast, for example, most medical research with most social science) in order to grasp the heterogeneity of science and the complexity of its relationships with policy. One might add, in the context of increasing interest in the evaluation of research, that these same considerations should urge caution in trying to apply blanket measures of research performance: the form, as well as the substance, of the products of different disciplines varies and demands great sensitivity in cross-disciplinary evaluations.

On the customer side of the picture, the authors show the variety of roles that exist in government, and the range of expectations that can be held of science. Officials concerned with policy-making, scientific advice, research management and research liaison have markedly different perspectives on science–government relations. Moreover, policymakers themselves are heterogeneous: some take a purely instrumental and short-term view of research; others, especially those with remits concerned more with policy analysis, are more interested in how research might help develop policy. Much emphasis is given to the need for, and complexity of, "brokerage" between departments and research councils, and between policy and science. We also learn a good deal about the need for sustained, long-term commitment to the development of the customer role, a process not aided by the relatively rapid turnover of staff on that side of the customer–contractor relationship.

Not surprisingly, the authors conclude that no single or straightforward model of science policy is appropriate, and that the metaphors of customer and contractor are oversimple. The customer metaphor implies that government can be clear and authoritative in stating its objectives "before entering the marketplace to purchase knowledge" (p.164). The contractor metaphor likewise assumes a coherent, identifiable and independent scientific community, able to negotiate from strength. In practice, both sides of the relationship exhibit a multiplicity of goals, functions, epistemologies and power bases. The social steerability of science depends, therefore, in a complex way on the effort put in by the customer, on the developmental state and institutional power of the scientific discipline concerned and on the level in the system at which one is working: micro-policy questions are easier to resolve than macro ones. Hence, finally, the conclusion that, at least in the broad field of social welfare, government should apply its energies to interaction with science rather than steerage of science: it should be concerned with the impact and implementation of research, and with the slow, steady and sustained development of strong communities of researchers and policy makers, rather than with rationalistic or imperative planning. □

East–West pairing

R.J. Elliott

Excitons.
Edited by E.I. Rashba and M.D. Sturge.
North-Holland: 1983: Pp.860. Dfl.425, $181.

Excitons is one of the first (actually Volume 2) of a series of books entitled *Modern Problems in Condensed Matter Sciences,* to be edited by V. M. Agranovich and A. A. Maradudin, and published jointly in English by North-Holland and subsequently in Russian by the publishing house Nauka. Each volume has editors and contributors who, like the general editors, are drawn from the Soviet Union and from the West.

As we all know, communication with Soviet colleagues is not as easy as we would like, partly because of language differences and partly because of the restrictions on travel to and from the Soviet Union. It is therefore particularly useful to have a series of up-to-date reviews which come in this form. It will make it less easy for scientists in the West to overlook Russian work in related fields.

Excitons are particularly appropriate for such a joint review. One leg of the theoretical foundation of the subject is firmly planted in Russia, on the work of Frenkel, Pekar and others, and relates largely to ionic and organic materials. The other is based in the West on the work of Wannier, Mott and others, and refers most directly to semiconductors. Experimental work in both areas has been carried out in parallel in all countries; for example, the rich exciton spectrum of cuprous oxide was evaluated in detail by Gross in Leningrad and by Nikitine in Strasbourg, and similar parallels exist in the work on polariton effects and on high-density excitons such as electron-hole droplets.

The book contains 18 chapters devoted to recent developments in this vigorous area of solid state physics and chemistry, their diversity displaying the remarkable wealth of the subject. Several refer to polariton (excitaron) effects, which lead to spatial dispersion and non-local effects, which appear remarkable and unusual in classical optics. Another group of papers deals with the effects of perturbations on exciton spectra, either arising from applied electric and magnetic fields, or from impurities. Isolated impurities cause trapping and in a semiconductor alloy the large number of impurities can give rise to different and important effects. Multi-exciton complexes are also considered, ranging from the relatively simple bi-excitons in CuCl to the many particle electron-hole complexes found in some semiconductors. Finally, the book's coverage has been extended to cover excitons in more specialized materials, including strained molecular crystals, magnetic insulators, and photosynthetic and other biological systems. Vibrational excitons (bound phonon pairs due to molecular anharmonicity) are also included.

The quality of the articles is uniformly high. There is naturally some variation in approach, but this is inevitable in the treatment of such a diverse field. The editors have brought together so many aspects of exciton physics that all those with an interest in the subject are bound to find not only useful reviews of their own speciality, but interesting insights into related fields. This volume augurs well for the rest of the series — I hope that at least some libraries will be able to afford it. □

R.J. Elliott is Wykeham Professor of Physics in the Department of Theoretical Physics, University of Oxford.

Lead in history and history in lead

Josef Eisinger

Lead and Lead Poisoning in Antiquity.
By Jerome O. Nriagu.
Wiley: 1983. Pp.437. £52.20, $73.10.

AMONG the technological arts discovered by our ancestors, none has played a larger role in shaping our civilization than metallurgy; and because the common minerals of lead melt at low temperatures, lead was the first metal to be refined. Lead may also have given rise to our oldest chemical industry, the production of white lead (ceruse), and is responsible for our oldest occupational disease.

The oldest lead object found by archaeologists is a string of beads worn in Anatolia some 8,000 years ago, and its use in jewellery suggests that this was a time when lead was still new and rare. Because of lead's malleability, corrosion resistance and other desirable qualities, human ingenuity devised many other uses for the metal and it attained great commercial importance in the classical world. The lead mines of Cartagena in southern Spain were exploited by Carthage before the area was conquered by Rome, and were worked by 40,000 miners who left a legacy of more than 10^7 tons of slag. In antiquity, lead was employed in coinage, glass, medicines, warfare (as sling bullets and in molten form during sieges), ship building, cosmetics (various oxides as eye shadows and so on), glazes for pottery, pigments, masonry (as mortar) and, of course, in "plumbing".

Smelting lead in the sixteenth century. The illustration comes from one of the works of Georgius Agricola (1494–1555), the German mineralogist who was the first to attempt to impose scientific order on the hitherto unsystematized knowledge of miners. (Reproduced from *Gmelins Handbuch der anorganischen Chemie*, Vol.47, Pt A1; Verlag Chemie, 1973.)

These are just a few of the myriad facts which Dr Nriagu has collected in his book, along with poetic and literary references to lead, arcane lead lore and the role of lead in alchemical theory. As a geologist and geochemist, the author is on familiar ground when dealing with the lead resources of the ancient world, including China and India, and with the contemporary methods of prospecting, mining and production. But he covers virtually all aspects of the metal's ancient history and has assembled an impressive bibliography from diverse disciplines which will be of great value.

The presentation of this encyclopaedic work is unfortunately not commensurate with its scope, however. The problem of organizing so much information into a readable text has not always been solved successfully: too many facts and quotations are offered without the necessary background or critical comment, and an unusually sloppy proof-reading job has left an abundance of annoying misspellings.

No aspect of the history of lead discussed by Dr Nriagu is likely to provoke as much interest and controversy as the prevalence of chronic lead disease in antiquity and his suggestion that it played an important part in the decline of the Roman Empire. This thesis was first advanced by Gilfillan in 1965 and has, ever since, irritated historians and classicists who are familiar with the complexities of that event. Gilfillan's historical model nevertheless has great popular appeal, and questions about it are raised in almost every discussion of the history of lead poisoning.

There exists, indeed, a great deal of literary, experimental and, lately, an increasing amount of archaeological evidence that many Romans were exposed to dangerous levels of lead. The most important exposure resulted from the unhappy custom of preserving and sweetening wine by the addition of a syrup *(sapa)*, which was prepared by simmering grape juice (must) in a lead kettle. It has been shown that *sapa* prepared according to any of several first-century recipes contained about $1 g Pb\ l^{-1}$, and when added to wine in the recommended proportion would produce chronic lead disease. Without *sapa*, or other preservatives such as resin which was, and is, preferred by the Greeks, the extensive wine trade of the Roman Empire would have been impossible.

Even those Romans who eschewed leaded wines ingested *sapa*, for it was a common cooking ingredient, and saturnine cosmetics and medicines were widely used. Dr Nriagu estimates that the rate of lead absorption ranged from $15 \mu g d^{-1}$ for slaves to $250 \mu g d^{-1}$ for aristocrats, compared to $2 \mu g d^{-1}$ in pre-technological societies and 30–50 $\mu g d^{-1}$ for the modern American.

Dr Nriagu raises the question why, in a society in which occupational plumbism, particularly among miners, was rampant, the connection between lead ingestion and disease remained undiscovered. Quite apart from the fact that miners were generally slaves or prisoners of war, beyond humanitarian concern or the care of physicians, the notion of a specific cause for a chronic disease, which we take for granted, was quite foreign to Graeco-Roman medicine. Galen and other contemporary physicians saw disease, including lead colic, as the result of an imbalance of the humours, and this view prevailed until some 1,500 years later when Paracelsus and his followers insisted that disease had specific chemical causes. The aetiology of the colic epidemics which were caused by the consumption of leaded wines and which persisted for many centuries was, in fact, not identified until 1696 (see *Med. Hist.* **26**, 279; 1982).

But while a strong case can be made for widespread lead disease in the Roman Empire and excessive drinking at the courts of some emperors, does it justify Gilfillan's hypothesis?

Dr Nriagu considers that the gluttony and other excesses of the Julio-Claudian and Flavian emperors were lead-related, although this is difficult to reconcile with the loss of appetite and constipation which are among the prominent symptoms of chronic plumbism. And did not the Empire attain its greatest wealth, power and extent under Trajan and other sober and effective emperors, who succeeded these sodden miscreants? It has on the other hand been suggested that gradual depopulation contributed to the failure of the Western Empire to defend itself against the invasions of the fifth century, and lead-induced infecundity may indeed have played a part in this. But the disappearance of the patriachal families in the first century can and has been explained otherwise, and may indeed have strengthened the state by introducing new blood into the most enduring political system which the West has evolved.

In the final analysis the evidence which has been marshalled in support of Gilfillan's hypothesis is, at best, anecdotal and occasionally spurious. There is little doubt that countless Roman citizens suffered and died from plumbism, but the link between that health disaster and the fall of the Roman Empire not only remains unproven but is probably unprovable. □

Chandrasekhar on Eddington

Fred Hoyle

Eddington: The Most Distinguished Astrophysicist of his Time.
By S. Chandrasekhar
Cambridge University Press: 1983. Pp.64. £7.50, $12.50.

ARTHUR Stanley Eddington was born on 28 December, 1882. Two centenary lectures were given in his memory, and the Master and Council of Trinity College, Cambridge, made the happy decision of asking Professor Chandrasekhar to deliver them. To this assignment he brought to bear all the care and scholarship which has attended his work down the years. The first of his lectures bears the same name as the book itself; the second is entitled "Eddington: The Expositor and the Exponent of General Relativity".

The first lecture has five sections: parts I and II are biographical, III is concerned with Eddington's early researches on stellar motions, IV is on stellar structure, and V is an amusing summary of Eddington's relations with his contemporaries, relations both friendly and stormy. The work on stellar structure, the internal constitution of the stars as Eddington preferred to call it, was of such massive proportions that I must pass it by except for the following brief sketch. Of the factors on which the luminous output of a star depends, Eddington showed that by far the most important is its mass. Given the mass it was possible to predict, without any knowledge of the source of a star's energy, what the luminous output must be, and to do so with a degree of accuracy that was considered remarkable in the 1920s.

Even within the short space available in a lecture, Professor Chandrasekhar brings out the remarkable degree to which Eddington was self-contained in his work, less influenced by others immediately around him than is usual for a scientist and reminding us of Peer Gynt's motto: To thyself be sufficient.

The second lecture has nine sections. Part I is a brief description of the origins of Einstein's theory, II is concerned with Eddington's early enthusiasm for the theory and his part in organizing the eclipse expeditions to test the predicted bending of light past the Sun, and III contains Professor Chandrasekhar's own recollections about this episode in Eddington's life. I was amused to find this problem: "A affirms that B denies that C declares that D is a liar" rearing its head again, a problem which last tormented me in the year 1936 when I attended Eddington's lecture course, "The Combination of Observations". There were turbulent arguments among us students about it, and frankly speaking I never could see that a determination of the probability that D spoke the truth had a solution. I am glad even after these many years to find Professor Chandrasekhar slipping in the extra information that D really made a statement. Possibly Eddington put in this condition himself, but it was hard to judge from his lectures; unlike the beautiful clarity of his writing, Eddington's lectures were a quagmire through which we heaved ourselves as best we could.

Part IV of the second lecture is an appraisal in glowing terms of Eddington's splendid book, *Mathematical Theory of Relativity*. Like Professor Chandrasekhar, I too continue to use it. In Part V we have a brief exposition of Eddington's attempt at a unified theory of gravitation and electromagnetism. Then after a light relief in VI, with much quoting of poetry, we come to what Professor Chandrasekhar calls the unhappy development of Eddington's ideas, to what he himself referred to as fundamental theory, an attempted fusion of physics and cosmology, which Professor Chandrasekhar describes with plenty of supporting quotations as a transition from sureness to cocksureness.

Where, one can ask, does praiseworthy sureness end and unpraiseworthy cocksureness begin? Since there are plenty of examples of important work being ignored for many years, it is hardly a satisfactory answer that the judgement lies in the reactions of a man's contemporaries. The issue is better related to fact. Where facts are many or are strong, it is possible to be sure. Where they are few, and are subject to a variety of interpretations, sureness becomes cocksureness, which unfortunately one must agree was the situation in Eddington's later work.

Nevertheless, one word of defence! Is Eddington's cosmology really negated because of the discovery of primordial helium and the microwave background? With a non-zero cosmical constant, one can have an initial big-bang that is adjusted by a special choice of parameters to pass asymptotically close to the Einstein static state, and with this special choice Eddington could have defended himself, as indeed Lemaître did. Discovery of the existence of primordial helium and the microwave background date from 1965. Is it not a little ominous for those who are so cocksure about their ideas in cosmology today that the factual evidence for their position has remained nearly static over almost two decades? □

Sir Fred Hoyle was an undergraduate student of Arthur Eddington's at the University of Cambridge in 1935-1936.

Son of John Paul

Culture of Animal Cells: A Manual of Basic Technique.
By R. Ian Freshney.
Alan R. Liss/Wiley: 1983. Pp.295. $49.50, £33.

THE washing of glassware, media making and cell production may seem generations away from gene cloning, monoclonal antibodies and fluorescent-activated cell sorting. They are not of course; but in large laboratories they are a central service and, if efficiently carried out, those who perform them may not be readily identified in corridors or canteens. In a decade of rapid advances, especially in molecular genetics, such services may be undervalued, but never by one used to a less-favoured environment.

The major part of Ian Freshney's book covers the setting up of a cell culture facility and the routine methods necessary to its function. The author then gives brief protocols for the more specialized techniques, referring always to the original publications. The bibliography is excellent and the cross-referenced list of equipment and reagents with addresses of manufacturers (in Europe and North America) will prove useful to many. The employment of trained staff, or advice from experienced colleagues, is preferable to book learning for those setting up a culture unit from scratch; but this book, with its large format, *Scientific American* lucidity, and generous use of diagrams, will be an essential adjunct.

The protocols, which have been taken direct from the Methods Book of a versatile laboratory, must be almost foolproof. Nevertheless, novices looking only for one particular procedure would be advised to spend some hours on a general browse. History records that many wrinkles and pitfalls are only obvious after expensive and time-consuming experience; Ian Freshney mentions them all somewhere but they could be constantly repeated.

Common sense suggests that the sections on organization and routine procedures will be of greatest use in developing countries, where budgets are tight and labour cheap. So a short appendix on alternative technology might have been included, while the absence of reference to probabilistic events in the sections on cell synchrony and physical cell separation could lead biochemists into an inappropriate use of cell populations. But these are small factors in a book invaluable in a wide range of rapidly expanding fields. The simple presentation of established routines, and introduction to the invaluable serum-free media of Ham and Sato, and to modern molecular techniques, make this a worthy competitor for Professor Paul's classic of 1959–1975. □

CHROMOSCAN 3

A new computing, scanning densitometer, so versatile it will sample anything...

...well, almost anything!

Perhaps a Picasso is a slight exaggeration! But it's no exaggeration to say that no other scanning densitometer can match the versatility of CHROMOSCAN 3.

All substrates up to 210mm square including gel strips, rods or slabs, TLC and HPTLC plates, acetate and paper can be scanned, using reflectance or transmittance in visible or ultra-violet, plus fluorescence and quench fluorescence modes.

And, CHROMOSCAN 3 is easily programmed via its microprocessor so that, even with the most complex test, the operator need only insert fresh samples.

Results are rapidly and clearly presented by the integral printer/plotter in an immediately usable form.

Peaks and troughs are automatically detected with per cent and total integral printed out as well as fraction concentrations and A/G ratio when appropriate.

Ease-of-use, speed of operation, accuracy and above all versatility make CHROMOSCAN 3 the most advanced computing scanning densitometer available.

Fronti rs in Neuropsychiatric Research

Edited by
Earl Usdin,
Department of Psychiatry and Human Behavior, University of California, Irvine, USA
Menek Goldstein,
Department of Psychiatry, New York University School of Medicine, USA
Arnold J.Friedhoff,
Department of Psychiatry, New York University School of Medicine, USA

August 1983; £40.00; 380pp; ISBN 0 333 347447

Based upon the proceedings of a CINP satellite symposium held in Corfu in June 1982, this book brings together contributions from the many fields involved in psychiatric research

Contents

Preface – Arnold J.Friedhoff; **Section I – Alterations of Neurotransmitter Systems in Affective Disorders –** Noradrenergic signal transfer as a target of antidepressant therapy – *Fridolin Sulser, Fumihiko Okada, D.Hal Manier, David D.Gillespie, Aaron Janowsky and Radhakanta Mishra;* Trans-synaptic mechanisms in the action of imipramine – *M.L.Barbaccia, De-Maw Chuang, O.Gandolfi and E.Costa;* Regional variations in 5-HT receptor populations and in ^{3}H-imipramine binding sites in their responses to chronic antidepressant treatment – *K.Fuxe, S-O.Ögren, L.F.Agnati, F.Benfenati, L.Cavicchioli, B.Fredholm, K.Andersson, C.Farabegoli and P.Eneroth;* The possible role of central epinephrine, α_2-adrenoreceptors and presynaptic dopamine receptors in affective disorders– *Menek Goldstein, Jorgen Engel, Isaac Regev and Shogo Mino;* Molecular aspects of regulation of α_2-adrenergic receptors – *D.C.U'Prichard, B.D.Perry, C.H.Wang, J.C.Mitrius and D.J.Kahn;* **Section II – Mechanisms of Action of Antidepressant Drugs –** Serotonin selective reuptake inhibitors - relationship between chemical structure and pharmacological effects *S.Agurell, H.Hall, T.Högberg, U.H.Lindberg, T.de Paulis, S.B.Ross and S-O.Ögren;* Effects of chronic administration of antidepressant drugs on central serotonergic receptor mechanisms – *S-O.Ögren, K.Fuxe, O.G.Berge and L.F.Agnati;* Neurochemical effects of the atypical antidepressant diclofensine in the rat – *W.P.Burkard, H.H.Keller, M.Da Prada and W.Haefely;* Oxaprotiline and its enantiomers: do they open new avenues in the research on the mode of action of antidepressants? – *A.Delini-Stula, A.Vassout, K.Hauser, H.Bittiger, U.Buech and H-R.Olpe;* Effects of single and multiple doses of antidepressant drugs on the ^{3}H-spiperone-labeled serotonin receptors in the frontal cortex of the rat – *Claes Rüdeberg;* Relationship between adaptive changes in brain α_2- and ß-adrenergic receptors following repeated imipramine, yohimbine and electroconvulsive shock treatment to rats – *A.I.Salama, A.Garcia, C.H.Wang, L.Lin and D.C.U'Prichard;* A review of the properties of a new specific 5-HT reuptake inhibitor - fluvoxamine maleate – *Jennifer S.Wakelin;* Biochemical and physiological mechanisms of action of carbamazepine in affective illness – *Robert M.Post and Thomas W.Uhde;* **Section III – Atypical Antidepressants and Mechanisms of Action –** Bupropion: an empirical pharmacological approach to drug development – *Loren Miller and Warren Stern;* Antidepressant and potential antimanic actions of GABA receptor agonists – *G.Bartholini, B.Scatton, B.Zivkovic, P.Worms and K.G.Lloyd;* Fluoxetine: a clinically effective non-tricyclic antidepressant – *Louis Lemberger, Ray Fuller, David Wong and Paul Stark;* The dexamethasone suppression test as a research variable – *John F.Greden;* **Section IV – Correlation of Biological and Clinical Factors in Affective Disorders –** Progress in pharmacotherapy of depression: research implications – *Anastasios Georgotas, Daniel Bush, William E.Hapworth, Mary Kim and Samuel Gershon;* Relationship of anxiety disorders to affective disorders – *David L.Dunner;* Application of sleep investigations in understanding antidepressant drug–clinical drug interactions – *David J.Kupfer and James Perel;* **Section V – Clinical and Basic Aspects of Affective Disorders –** Biochemical aspects in striatal dopamine receptor desensitization – *Ingeborg Hanbauer and Maurizio Memo;* Receptor–receptor interactions: possible new mechanisms for the action of some antidepressant drugs – *L.F.Agnati, K.Fuxe, F.Benfenati, L.Calza, N.Battistini and S-O.Ögren;* A double-blind comparative trial of oxaprotiline with amitriptyline and placebo in outpatients with moderate depression: relationship of urinary MHPG levels – *The Oxaprotiline Study Group;* Platelet α_2-adrenergic receptor activity in clinical studies of depression – *R.H.Lenox, J.E.Ellis, D.A.Van Riper, Y.H.Ehrlich, J.M.Peyser, J.E.Shipley and L.A.Weaver;* The olfactory bulbectomized rat as a model of depression – *Suzanne Jancsár and B.E.Leonard;* Closing Remarks – *Peter Hartocollis;* Index.

Computers in chromatography

Richard Patience gives a personal view of how to tackle the growing array of computers being used in chromatography.

How many chemists and biochemists, when faced with a computerized chromatography system, know which button to press and when to press it, but have no idea how the system works? My own first encounter with such a system — a DEC PDPB/e laboratory computer attached to a capillary gas chromatograph/mass spectrometer (GC/MS) — only served to give me a firm conviction that it was all far too complex and that I would never learn to use it. Of course, in time, I did and, what is more, became quite at home with it. But it is one thing to know what to do with a computer keyboard and quite another to know why you do it!

In the mid 1970s, when I first started working with computerized chromatography, laboratory computers were quite rare — and quite large — and generally found only on more sophisticated and expensive equipment, like GC/MS. Temperature and solvent gradients in GC and liquid chromatography (LC) respectively were set up manually. The Pye 104, the Perkin Elmer F17 and the Varian 2700 GCs were all operated in this way, whilst the major LC company, Waters, had the M660 gradient analysis programmer, which has only recently been superceded by the microprocessor-driven M680. 'Data collection' was by chart recorder.

Shortly after I embarked on my research career, there were two major developments. First, in gradient formation, microprocessors began to replace manual control, particularly in GC. Microprocessor-controlled gradients were set up from a small keyboard and parameters such as gradient slope were stored in the memory. Automatic cooling at the end of the run meant that the whole cycle could be preprogrammed and initiated by a single key, but unfortunately you still had to inject the sample.

The second improvement came with the arrival of integrators to calculate peak areas for quantitation. This was a real advantage — both in terms of time and accuracy — even though some early models produced only a numerical strip print out and no chromatogram.

One of the main advantages claimed for microprocessors was an improvement in reproducibility of repeat analyses, in other words an increase in retention times. I have no reason to dispute that, but in my opinion there were, and still are, two disadvantages to microprocessors. The problem with many systems was that, unlike manual units, once started the programme could not be altered without aborting the whole run. This gives a degree of inflexibility that is fine for routine analyses but can frequently be inconvenient when dealing with less well defined samples. What is more, gradient controllers and integrators originally had to be programmed and started separately. The poor user needed three or four hands — one to inject (two for the less steady-handed), one to initiate the gradient programmer and one to start the integrator.

Now, of course, all this has changed and often the whole analysis sequence is completely automatic. The computer boom has reached even HPLC — slower to benefit than GC but rapidly catching up. So, faced with the present array of chromatographic systems, how does the practical biochemist or chemist decide which best suits his or her needs? The mechanical aspects are relatively easy; from practical experience of dismantling pumps and setting up equipment it is possible to assess the mechanics of an HPLC system. But computers — particularly software — are much harder to evaluate without actually using them. If this be the case, then where does one start?

Choosing a system

One tactic is to begin with an assessment of the facilities available from the present generation of computers. Fig. 1 shows a stylized configuration of a hypothetical HPLC system. The controller can be programmed to initiate and control a number of events at preselected times. Furthermore when remote computers or terminals are linked up, the system can be controlled remotely and data can be generated and sent to distant units.

The range of functions offered by individual manufacturers varies considerably, of course. More sophisticated systems include the Varian Vista 402, the Spectra Physics Labnet, Waters' M721 and associated units, the LDC CCM system, Perkin Elmer's Series 4 + Chromatographics 2, Pye Unicam's 4850, Hewlett Packard's 1090 + HP85, Dupont's 8800 and Sentinel, and Gilsen and ACS, which use Apple IIe computers.

Why, though, should such sophistication interest a typical chromatographer? One advantage of microprocessor-based systems has already been mentioned — increased reproducibility of retention times of repeat analyses. However, to me the main advantage lies in the ability to coordinate different units and events from a single keyboard. Gone is the need for three hands to start a run; with fully automated instruments one finger may be enough for dozens of analyses. Of course there are always disadvantages. One of these is cost — around £7,000 to £10,000 at present on top of the HPLC cost. Another is simply the level of complexity of the system itself, which can be confusing for non-specialists, and inevitably introduces a degree of redundancy to the system. Nevertheless, I am sure that the use of computers in chromatography will continue to increase, particularly as they become cheaper. □

Richard Patience is in the department of chemical endocrinology at Saint Bartholomew's Hospital, London.

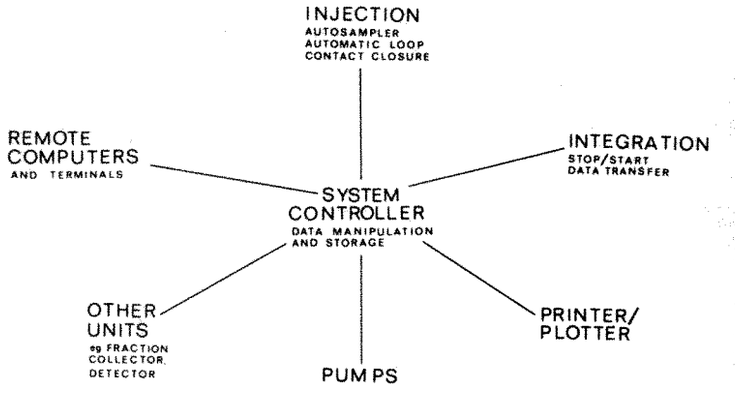

Fig. 1. Stylized configuration of a computerized HPLC system. The controller regulates; (1) injection, which may be by autosampler, automatic loop (user loads loop, controller injects it) or contact closure (user loads and injects, which closes electrical contact and starts controller program); (2) pumps: gradient formation preprogrammed; (3) integration: stop/start or integration and transfer of data to the controller for manipulation, storage on disk or tape, or plotting; (4) printer/plotter; (5) other units, such as a fraction collector or detector; (6) remote computers or terminals.

High performance liquid chromatography

● HPLC Technology has launched a range of HPLC column block heaters. The heaters operate in the temperature range ambient to 99°C and reproduce temperatures with an accuracy of ± 0.5°C; their temperature rise time from ambient to 60°C is 10 minutes. Columns of various lengths (with or without pre-columns) can be used. Heaters are available for larger diameter columns as well as for heating the injection system.
Circle No. 100 on Reader Service Card.

● Perkin-Elmer has introduced several new HPLC columns. The 3×3 columns, so-called because they are 3 cm long and use 3-μm packing materials, offer reduced analysis times and lower solvent consumption. The short column length eliminates high back-pressures. The columns can be used with most liquid chromatography systems, but operate best with Perkin-Elmer equipment. The combination of the Perkin-Elmer series 4 solvent delivery system, the LC-85B detector with a 1.4-μl flowcell and 3×3 columns provides the fastest analyses.
Circle No. 101 on Reader Service Card.

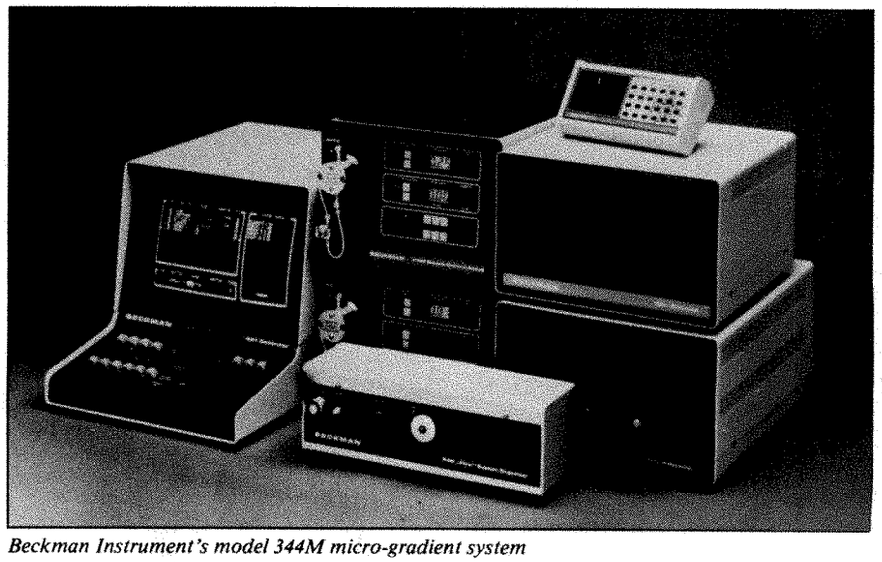
● Bio-Rad's HPLC column heater will produce temperatures between ambient +5°C and 150°C with accuracy of ± 2°C, while operating in environments with temperatures between −5°C and 50°C. A thermostat set to turn off power automatically at 180°C provides over-temperature protection. After a standard warm up period, the column heater will maintain temperatures with a stability of ± 0.1°C. The heater has a dual column capacity, and can accommodate columns from 5 to 30 cm in length and from ¼ to ½ inch in diameter. A 'solvent preheat block' is also available as an accessory.
Circle No. 102 on Reader Service Card.

● A series of prepacked HPLC columns of high-pressure hydroxyapatite has been introduced by Bio-Rad. The Bio-Gel HPHT system has a standard column, which is 100 + 7.8 mm and has a capacity of 100 mg for protein or 5 mg for DNA. Separations can be concluded within 30 minutes. Any technique using standard hydroxyapatite protocol can be applied to the high-pressure system. The columns can be used to purify monoclonal antibodies from mouse ascites fluid and to purify plasmids. They are either available individually or as a system which incorporates the use of a sacrificial guard column.
Circle No. 103 on Reader Service Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Service Card bound inside the journal.

● Gelman Sciences has introduced a miniature disposable membrane filter unit designed for HPLC users. The Acro LC13 has a 0.2, 0.45 or 1.0-μm, 13-mm diameter fluoropolymer membrane filter sealed into a polypropylene housing. This reduces liquid sample loss to 0.014 ml. The new fluoropolymer membrane is naturally wetted by aqueous samples whilst retaining chemical compatibility with solvents such as methanol, chloroform, *N*-heptane, methylene chloride and acetonitrile.
Circle No. 104 on Reader Service Card.

● A new alkylphenone HPLC internal standard kit is now available from Pierce. Alkylphenones are a family of neutral compounds. Neither solvent modifiers nor acidic nor basic buffers will affect their retention volume. Due to their wide solubility range, both polar and non-polar solvent systems can be used. Nanogram quantities are detectable with a common UV detector. Each kit contains one gram each of nine alkylphenones.
Circle No. 105 on Reader Service Card.



● A new HPLC pumping system has been introduced by Knauer. It has an electronically-controlled motor, two sapphire pistons and two cartridge-type ruby ball check valves. Its unusual cam design gives correct precompression and will compensate the pressure feedback electronically for liquid compressibility. Changing from micro- to macro-chromatography is achieved by exchanging pump heads. The unit can be interfaced with most commercial controllers or with its companion microprocessor programmer models 50A and B.
Circle No. 106 on Reader Service Card.

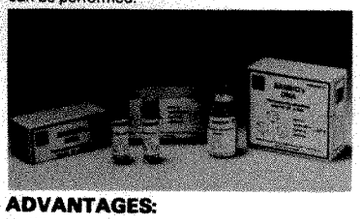
● A new carbohydrate HPLC column is now available from IBM Instruments. The new column is packed with a 5-μm stationary phase. Analyses can be performed at room temperature using a mobile phase of acetonitrile and water. Typical applications of the new column include baseline separation of critical sugars, separation of saccharides from polysaccharides, separation of polysaccharides and maltose/isomaltose ratio determination. The carbohydrate column can be supplied in a 4.5×250 mm size.
Circle No. 107 on Reader Service Card.

● Distilled in glass and filtered through 0.2-μm Teflon membranes, Pierce HPLC/spectro grade solvents are intended to have both HPLC and spectrophotometric applications. Label information includes: formula, formula weight, safety data, flash point, first-aid procedures, UV absorbance data, gas chromatography assay, evaporation residue, and water content.
Circle No. 108 on Reader Service Card.

● Two types of guard columns have been introduced by IBM Instruments to prevent liquid chromatography samples with non-eluting materials contaminating HPLC columns. The guard columns are compatible with HPLC instrumentation. One of the columns has normal (silica) pellicular packings while the second has reversed-phase (octadecyl) packings. Each guard column kit contains 4.5 × 50 mm repackable hardware and 6 g of packing material. Replacement packing is available in 10-g units.
Circle No. 109 on Reader Service Card.

● Beckman Instruments has introduced the model 344M micro-gradient system which is designed to work with 2-mm HPLC columns. The system includes the model 114M pump which features flow ranges of 0.001 to 1.00 ml min^{-1} or 0.01 to 9.99 ml min^{-1}. A new system organizer incorporates a low column dynamic mixer which is designed to blend solvent combinations at low flow rates.
Circle No. 110 on Reader Service Card.

Beckman Instrument's model 344M micro-gradient system



DO YOU WORK WITH CULTURED CELLS OR BIOPSY SPECIMENS?

THEN YOU KNOW THAT DNA IS THE BEST REFERENCE VARIABLE

SANBIO INTRODUCES: NUCLESAN 100

QUICK ANALYSIS:

By means of the test combination kit double stranded DNA can be measured adequately in a very short time. With one package 60-120 tests (depending on the DNA-range of the sample), including the calibration curve samples, can be performed.

DNA-RANGE:

The method* allows to measure small quantities of DNA *(5-30 µg)* in cultured cells or biopsy specimens. It opens the possibility of relating biochemical parameters to the exact number of living cells.

ADVANTAGES:

Up till now methods for measuring double stranded DNA were limited in their application because of low sensitivity or because of complex extraction procedures (Burton, K. Biochemical Journal (1956) 62, 315-322). The actual method liberates DNA in one single step from cells or biopsy specimens. Then the DNA is complexed stochiometrically to a substance with high affinity to DNA. The complex formed can be determined fluorimetrically. All ingredients are available in one package in balanced quantities. The clear user's information in four languages enables a simple quantitative determination for every scientist.

CGC Glass Cartridges

A new system for HPLC in glass-bodied columns

- chemical inertness as well as unequalled surface smoothness of the internal tube wall
- usability under high pressures due to a special hardening procedure for the glass tube
- easy connection to an optional HPLC unit
- advantageous price compared with steel columns

British Journal of PHARMACOLOGY

The most respected journal for those professionally involved in the pharmacological sciences.

Pharmacologists, like other scientists, have to cope with ever-increasing amounts of information. A publication which only includes papers of the highest standard and relevant to current pharmacological research is obviously required. The *British Journal of Pharmacology* is just such a journal.

Original papers, submitted from all parts of the world, examine every aspect of drug action. Chemotherapy, systemic pharmacology, drug mechanics, pharmacokinetics, psychopharmacology, autopharmacology are all given extensive coverage. *British Journal of Pharmacology* is thus a vital source of information for physiologists, clinicians, immunologists, molecular biologists and biochemists as well as pharmacologists.

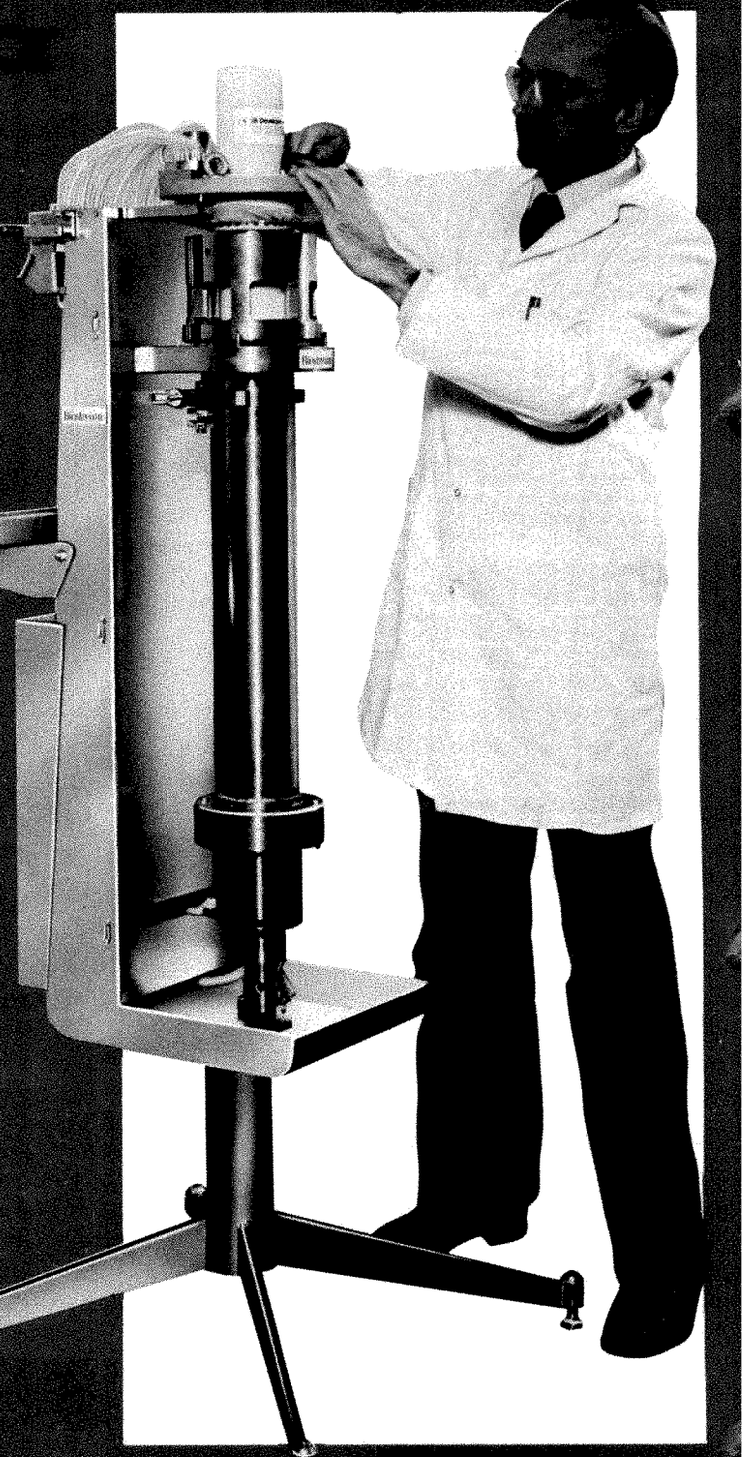
BIOSTREAM

[illegible] Reveals For [illegible]



The BIOSTREAM separator provides continuous, free flow electrophoresis on a scale not previously available. Designed for production plant operation it has a throughput up to 1000 times that of other commercial electrophoresis systems.

BIOSTREAM separates rapidly and reproducibly with excellent retention of biological activity. This enables better product yields and purities to be achieved. A wide range of biological materials may be processed including simple molecules, macromolecules and whole cells.

Although intended for large scale applications BIOSTREAM can also process volumes of less than one litre Thus identical separations can be performed at laboratory, pilot plant and production scales.

The P-500 pump from Pharmacia

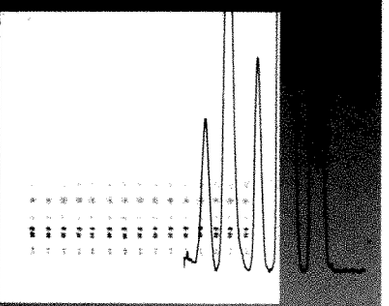
Isco's Retriever II

Steel tanks from Pharmacia

Chromatographic accessories

● The new Retriever II linear fraction collector from Isco can handle up to 174 tubes, yet it takes up just a square foot of bench space. Racks are available to hold either 174 of the 12 and 13-mm diameter test tubes, 116 of the 10 to 18-mm tubes, or 42 scintillation vials. The top of the collector can be lifted off. Retriever II can be programmed to collect by time, drop, discharges from a siphon or volumeter, or pulses from a pump.
Circle No. 111 on Reader Service Card.

● Pharmacia Fine Chemicals has introduced a new high precision pump, the P-500. This solvent delivery system is for use when a constant, precise flow is required, as in general liquid chromatography. It is designed for use with Pharmacia's new FPLC high performance chromatography media but is also compatible with traditional separation methods. The pump can be used at atmospheric pressure for columns of Sephadex and Sephacryl. Piston movement is controlled. All materials in contact with the eluent are compatible with aqueous buffers and the borosilicate glass used in the P-500 is impervious to solvents.
Circle No. 112 on Reader Service Card.



● A range of power supplies is now available from Uniscience which produce from 250–4,000 V. It includes the EC300 with the isoelectric focusing end point detector. Also on offer is a family of gradient formers for producing linear, convex, concave and exponential gradients. Two microdialysis models (4 and 24 chambers) are also offered.
Circle No. 113 on Reader Service Card.

● Pharmacia Fine Chemicals has a range of stainless steel tanks that facilitate the preparation, filtration, delivery and collection of buffers and samples used in large scale chromatography. The range is comprised of a buffer preparation tank (capacity 300 litres) fitted with a circulation pump and filter, flat-bottomed buffer tanks (25–300 litres) and conical sample tanks (50–300 litres).
Circle No. 114 on Reader Service Card.

● A dedicated software package has been developed for ion chromatography by Nelson Analytical. This software is offered as part of the standard chromatography software package for Nelson Analytical's 4400 series multi-instrument data systems, which are based on the HP 200 series desktop computers. Data from up to 10 ion chromatographs (20 detectors), or from conventional gas and liquid chromatographs can be processed on the same system simultaneously. Data sampling rates for this system range from one point every 10 seconds to 100 points every second.
Circle No. 115 on Reader Service Card.

● Scientific Glass Engineering is now producing the items required to combine on-column injection with bonded phase capillary columns. These include on-column injectors with special vitreous silica needle syringes, a range of bonded phase columns in vitreous silica and low dead-volume connectors with graphite, vespel or kalrez ferrules.
Circle No. 116 on Reader Service Card.

A chromatography laboratory is incomplete unless it includes instrumental thin-layer chromatography.

While other chromatography techniques are often employed, (instrumental) TLC has been found to be the method of choice for many applications.

However, this is only possible if appropriate instrumentation is applied to the task!

COMPLETE TLC SYSTEMS – everything from the simplest tool to fully automatic quantitative scanning equipment – all from one source – is only available from CAMAG.

Consult your CAMAG specialist.

Columns and packing materials

● IBM Instruments has added a column for molecular weight analysis to its line of gel permeation chromatography/size exclusion chromatography (GPC/SEC) columns. The new GPC/SEC Scout column is available in a cross-linked divinylbenzene gel. This means that many organic solvents can be used with it, including dimethylformamide. The Scout column simplifies the use of column sets and can be used for molecular weight distribution analysis of polymers with a range of 500 to 4,000,000.
Circle No. 117 on Reader Service Card.

● Pharmacia Fine Chemicals has introduced its Monobeads (see *Nature* **305** 95) into prepacked ion exchange columns. An integral part of their fast protein liquid chromatography (FPLC) system, Monobeads represent a new generation of pressure and *p*H stable chromatographic absorbents. They have been designed for rapid protein, peptide and polynucleotide separation. The Monobeads are available in 3 dimensions — Mono Q for anion exchange, Mono S for cation exchange and Mono P, a chromatofocusing matrix which separates proteins according to their isoelectric points. Their monodispersity allows high efficiency packing and medium pressure operation. They feature a particle size distribution of 9.8 μm + 2%. The prepacked columns are made of borosilicate glass, which enables the gel bed to be seen.

Liposomes

A **new** laboratory instrument (LIPOPREP®-GD-1) is available for the **reproducible** preparation of extremely homogeneous, unilamellar liposomes of controllable size. The instrument permits the **simultaneous use of five different lipid mixtures** and provides extensive versatility. Applications range from membrane reconstitution, remodelling of cellular functions, liposome drug delivery systems, microanalysis of drugs and metabolites, to antibody targeting, clinical diagnostic assays, and genetic engineering.
For details write to:
DIANORM-Geräte, P.O. Box 126, D-8 München 65, FRG.

Circle No.11 on Reader Service Card.

● A series of wide-pore silica-based materials has been produced by HPLC Technology for the separation of proteins, peptides and enzymes. The TechoGel range comprises 200 and 300 Å pore-size silicas, in both 5-μm and 10-μm particle sizes. The TechoGel range consists of a GP phase for gel permeation up to MW 250,000; ion exchange, which covers weak anions, weak cations and strong cations; reverse phase — C4, C6, C8, C18, phenyl and diphenyl and preparative phases, including ion exchange and reverse phase. TechoGel is available in prepacked HPLC columns or as loose media.
Circle No. 119 on Reader Service Card.

● Du Pont has introduced a Zorbax phenyl column for HPLC with reversed phase selectivity for moderately polar compounds, including many pharmaceuticals. The new phenyl column offers an alternative selectivity to other Zorbax alkyl group reversed phase packings, such as ODS, C8 and TMS. This means that chromatograms of two photoreactive chemicals (cyclohexylacrylate and benzophenone) eluted from Zorbax phenyl and C8 columns under identical conditions will show reversed elution order. The Zorbax phenyl column also gives a small shoulder on the dimethoxyacetophenone peak. The phenyl column contains 5-μm Zorbax silica packing modified with a dimethylaryl silane, using procedures to maximize monolayer surface coverage. Post capping completes surface coverage. The columns have a 4.6-mm internal diameter and are available in 15 and 25 cm lengths. Performance characteristics described by typical theoretical plates (N) are 9,000 for the 15-cm column and 15,000 for the 25-cm column. The compound used in the characterization was toluene.
Circle No. 120 on Reader Service Card.

● The new liquid chromatography chambers from Revco have four temperature controls, display temperature in all four quadrants continuously and have an alarm system that tests itself automatically every 24 h. They also have computer connections for collecting, storing and monitoring temperature data automatically. The chambers also have an optional auto-dialer alarm system whereby they will call any of 10 numbers, a 240-day electronic temperature recorder and a remote audio alarm.
Circle No. 121 on Reader Service Card.

● Two new chiral columns are now being produced by J.T. Baker Chemicals that are designed to separate racemic mixtures and stereoisomers. Two types of column have been produced; the DNBPG ionically bound to 5-μm aminopropyl silica (60-Å) for lipophilic samples and a covalently-bound DNBPG which is suitable for pharmaceutical applications.
Circle No. 122 on Reader Service Card.

● J.T. Baker has introduced a range of HPLC columns containing Bakerbond materials bonded to 5-μm spherical silica gel with a pore diameter of 60 Å. The range includes octadecyl (C18), octyl (CS), quartenary amine, aliphatic sulphonic acid, diol, aliphatic carboxyl, diphenyl and cyano. The columns are available in the standard size of 4.6 mm (internal diameter) × 25 cm with SSI fittings. In addition a number of wide-pore columns has been introduced for the separation and purification of proteins, peptides and oligonucleotides. The wide-pore columns have a pore diameter of 330 Å. The range of columns includes octadecyl, octyl, diphenyl, cyano and polyethyleneimine. The Bakerbond bonded phases are also available separately with particle sizes of 5 μm (spherical), 10 μm (irregular) and 40 μm (irregular).
Circle No. 123 on Reader Service Card.

Electrophoresis

● The Dionex IonPac membrane reactor uses a new method of reagent introduction which aids in the determination of metals, sequestering agents, silicates and amino acids. The membrane reactor is for use with the Dionex post column reactor and a series 2000i ion chromatograph. The membrane reactor's fibre membrane is permeable to a variety of reagents. During operation, pressurized reagent from the pulseless post column reactor is introduced into the column effluent stream along the length of the fibre membrane. This means that reagents are added at a pulse-free flow-dependent rate. The volume of reagent introduced in this method is minimal, reducing analyte dilution effects. Flow-dependent noise and dilution effects are also reduced.
Circle No. 124 on Reader Service Card.

● A casting tray is being marketed by Bio-Rad that can be used to produce ultra-thin gels for thin layer electrofocusing. The tray allows 0.4-mm polyacrylamide gels to be cast on glass plates or, when used in conjunction with Bio-Rad's new gel support film for polyacrylamide, allows 0.2-mm polyacrylamide gels to be produced.
Circle No. 125 on Reader Service Card.

● The Gelman electrophoresis system, which uses cellulose acetate membranes as support medium, is based upon the established semi-micro II electrophoresis chamber. This chamber has been designed to reduce running costs. It requires 200 ml of buffer to effect separation of up to 96 samples, including standards and controls. Up to 24 samples may be separated simultaneously. Sample application is by either a four- or an eight-place push button

UNIVERSITY OF CHICAGO

ASSISTANT OR ASSOCIATE PROFESSOR IN THE RESEARCH ASSOCIATE TRACK

o assume major responsibility in a ellular electrophysiology laboratory tudying arrhythmogenesis and the ctions of antiarrhythmic drugs. xperience in voltage clamping, able analysis, ion sensitive micro- lectrodes, and computer pro- ramming preferable. Excellent cientific environment.

Renewable term appointment with ull fringe benefits. Immediate vailability.

Please send curriculum vitae, epresentative reprints, and names of hree references to: Morton F rnsdorf, MD, Chief, Section of ardiology, University of Chicago lospitals, Box 423, 950 E 59th treet, Chicago, Ill 60637.

(NW285)A

THE UNIVERSITY OF MANCHESTER

DEPARTMENT OF ORAL AND MAXILLO-FACIAL SURGERY

RESEARCH ASSOCIATES (TWO)

Applications are invited for these two posts for an initial period of three years, to undertake research in laboratories within the Department of Pharmacology.

Applicants should have experience in either electrophysiology or microvascular pharmacology. Initial salary range pa: £7,190 — £8,530. Superannuation.

Further details and informal visits by contacting Professor J P Rood, Department of Oral and Maxillofacial Surgery, Turner Dental School, Higher Cambridge Street, Manchester M15 6FH (061-273 5252).

Applications, with a curriculum vitae and the names of two referees, to be submitted by March 5th.

(1149)A

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

MICROBIOLOGY DEPARTMENT

A research scientist is required to devise and develop new rapid methods for estimating the bacteriological quality of milk, milk products and other foods. The further development and automation of the direct epifluorescent filtration technique (DEFT) is envisaged. Additionally, the application of radioimmune, ELISA, and allied techniques for food analysis will be explored.

Appointment will be as Scientific Officer (£5,682 — £7,765) or Higher Scientific Officer (£7,149 — £9,561). Non-contributory superannuation.

Candidates should have a First or Upper Second Class Honours degree in biological or physical sciences with at least two years' relevant post-qualifying experience for appointment as HSO.

Applications to the Secretary, N.I.R.D. Shinfield, Reading RG2 9AT.

Please quote reference 83/19.

(1168)A

UNIVERSITY OF LEEDS

DEPARTMENT OF EARTH SCIENCES

LECTURER

Applications are invited for the above post available from 1 October 1984. The duties of the post will include teaching Engineering Geology students at undergraduate and MSc level; applicants should have suitable qualifications and preferably some research or industrial experience in this area.

Salary on the academic scale for Lecturers (£7190 — £14125) according to age, qualifications and experience.

Informal enquiries may be made to Professor J C Briden, telephone (0532) 431751, ext 6415.

Application forms and further particulars may be obtained from the Registrar, the University, Leeds LS2 9JT, quoting reference number 49/26. Closing date for applications 27 February 1984. Overseas applicants may apply by telegram or telex (556473) in the first instance.

(1165)A

University of Massachusetts Medical School
Interdepartmental Program in Environmental Health Sciences
Two Senior Tenure Track Positions Available
SPONSORING DEPARTMENTS: Family & Community Medicine, Pathology & Pharmacology

PREFERRED AREAS OF GENERAL RESEARCH INTEREST include Mutagenesis/Carcingenesis, and Inhalation/Pulmonary or Reproductive Toxicology.

The University of Massachusetts Medical School seeks to recruit two Senior faculty members to join several of its faculty in developing the above interdepartmental program. Appointments may begin in the fall of the 1984-85 academic year. The requirements of each participating department are described further below. Multidepartmental, joint appointments will be considered, and applications and inquiries from established teams of investigators working in one or more of the above areas are encouraged. Each faculty member will be expected to pursue an independent research program and to participate, in the context of an interdepartmental program, in service, medical education, and/or the education of graduate students in an institutional Ph.D. Program in Medical Sciences. General inquiries or letters of application (including a curriculum vitae and a list of three references) should be sent before 31 March 1984 to:

Neal C. Brown, Professor & Chairman
Department of Pharmacology, University of Massachusetts Medical School, 55 Lake Avenue North,
Worcester, MA 01605; (617) 856-2151.

POSITION REQUIREMENTS

FAMILY & COMMUNITY MEDICINE POSITION

Associate Professor or Professor with M.D. and/or Ph.D. and an established research program in one of the areas cited above. **Preferred Research Interests** include the study of the relationship of environmental/occupational exposure to effects on human health. Other duties would include the performance of health/exposure assessment of environmental/occupational hazards and participation in the formulation of related public policy.

For further specific information contact Dr. Barry Levy, Department of Family and Community Medicine, UMMC, Worcester, MA 01605. (617) 856-2151.

PATHOLOGY-PHARMACOLOGY POSITION

Associate Professor or Professor with M.D. and/or Ph.D. and an established program in one of the areas cited above. **Preferred Research Interests,** regardless of the appointee's departmental affiliation and the specific areas of interest, his/her research should incorporate the use of analytical chemistry and related techniques. The specific research interests should fall within the context of the areas cited above and be relevant to the broad discipline of environmental-toxicologic pathology or pharmaco-toxicology – including the pharmacokinetics and metabolism and mutagenic/carcinogenic effects of drugs and environmental chemicals.

For further specific information contact as appropriate – Dr. Neal Brown (Pharmacology, see above) or Dr. Guido Majno, Chairman, Department of Pathology, UMMC, Worcester, MA 01605; (617) 856-2115.

University of Massachusetts Medical Center

55 Lake Avenue North Worcester, MA 01605

An affirmative action equal opportunity employer (NW277)A

Biotechnology Australia

Career Opportunities in Biotechnology

Biotechnology Australia Pty Ltd, Australia's leading biotechnology research company, is in the process of expanding its research and development activities. There are immediate opportunities for the research and development positions listed below.

The company provides a first class research environment for over 70 staff in modern laboratories on Sydney's North Shore. The laboratories are equipped with a full range of instruments and fermenters necessary for projects requiring the skills of molecular biologists, microbiologists and biological chemists. Topics under investigation include studies of new methods for vaccine production with recombinant DNA techniques, biological control of insect pests with genetically modified bacteria and parasitic nematodes, and the microbiological leaching of minerals. Most projects involve collaboration with leading groups in universities, CSIRO and research institutions.

The research group is supported by experts in planning and evaluation and there are extensive facilities for scale-up and process development.

Applications are now invited for the following seven positions.

Molecular Biologists

Position No. 1001 is for a candidate with Post-Doctoral experience in molecular biology or allied fields of biochemistry or microbiology, for appointment as a Research Scientist.

Position No. 1002 is for a candidate with an Honours Degree in similar subjects or in immunology, for appointment as an Experimental Officer.

Position No. 1003 is for a Post-Doctoral Fellow funded for 3 years in the first instance. Training in recombinant DNA and allied immunological techniques is required.

Position No. 1004 is for a Post-Doctoral Fellow funded for 2 years in the first instance for the development of vaccines against enteric infections using recombinant DNA technology.

Fermentation Scientist

Position No. 1005 is for a candidate with an Honours Degree in microbiology or fermentation with knowledge of chemical or biochemical engineering. Appointment will be at the Experimental Officer level to work on solid and liquid fermentations and product recovery.

Entomologist

Position No. 1006 is for a candidate with an Honours or higher degree in entomology for appointment as an Experimental Officer. The position would be for 2 years in the first instance.

Biotechnologist

Position No. 1007 is for a candidate with an Honours Degree in microbiology, biochemical engineering or allied discipline for appointment as an Experimental Officer. The position would be for 2 years in the first instance.

All positions carry salaries and conditions of employment competitive with other leading research organizations.

Applications including a c.v. and names of two referees should be sent to:

Professor N. S. Willetts
Director of Research
Biotechnology Australia Pty. Ltd.
P.O. Box 20
Roseville N.S.W. 2069 Australia

(W712)A

BEATSON INSTITUTE FOR CANCER RESEARCH
POST-DOCTORAL SCIENTIST

There is a vacancy for a scientist with training and experience in nucleic acid biochemistry and/or molecular biology and/or cell biology to join a group studying human colorectal cancer and metastasis. Appointment will be to University Research Staff Range IA (£8,530 to £11,615).

Applications with names and addresses of two academic referees and complete cv to Dr. G. D. Birnie, Beatson Institute, Garscube Estate, Switchback Road, Bearsden, Glasgow G61 1BD Scotland. (1171)A

THE INTERNATIONAL CENTRE OF INSECT PHYSIOLOGY AND ECOLOGY
PO BOX 30772, NAIROBI, KENYA

Applications are invited from suitably qualified candidates for the position of

ACADEMIC COORDINATOR

for the African Regional Postgraduate Programme in Insect Science (ARPPIS). ARPPIS is a collaborative high-level research training programme between the International Centre of Insect Physiology and Ecology (ICIPE) and eleven Participating Universities in Africa. The programme, which is limited to PHD training, is based at the ICIPE, which acts its executing agency. Coursework is offered as advanced refresher courses in insect ecology, biostatistics, physiology and biochemistry, pathology, taxonomy and morphology by an international teaching staff. Participating Universities are responsible for nomination of Postgraduate students, who are selected by an Academic Board comprising representatives of the participating Universities; the latter offer the degrees. ARPPIS became functional in March 1983, with student body of eight PhD candidates from five African countries.

ACADEMIC COORDINATOR (Ref: SCI/84/1)

QUALIFICATIONS: The candidate should be an experienced academic lecturer level upwards, with research and teaching experience in the biological sciences. Experience in project administration, particularly in a setting with tradition on Postgraduate training will be a distinct advantage.

RESPONSIBILITY: The selected candidate will assist the ICIPE in the planning of the academic programme, its implementation and coordination, and act as Secretary to the Academic Board of ARPPIS. The board has responsibility in the recruitment of the teaching staff, the selection of students, and the reviewing of curricula and examinations. In addition to his other duties, the appointee is expected to participate in the teaching and supervision of the Postgraduate students.

SALARY AND TERMS: Negotiable, and include attractive benefits. The successful candidate will be offered an initial two-year appointment, with the possibility of extension.

Applications, giving detailed information on general education, professional qualifications, experience, marital status, age, present terms of employment (including salary), names and addresses of four referees (including one personal referee), and photocopies of relevant certificates (which once submitted will not be returned) should be addressed to:

The Administrative Manager,
ICIPE Research Centre,
PO Box 30772,
NAIROBI, Kenya

CLOSING DATE: 21st March 1984. (W736)A

UNIVERSITY OF LANCASTER
Department of Environmental Sciences
RESEARCH ASSOCIATE

Applications are invited for the post of postdoctoral Research Associate to work with Dr. R. M. Harrison, Dr. M. Kelly and Dr. S. R. Aston on a two year study of transuranic radionuclides in the estuarine environment. Applicants should possess a PhD degree, and research experience in environmental chemistry or geochemistry would be advantageous. Salary is in the range £7,190 – £8,530 p.a.

Further particulars may be obtained (quoting reference LO11/R) from the Establishment Office, University House, Bailrigg, Lancaster, LA1 4YW, where applications (seven copies) naming three referees, should be sent NOT LATER THAN 24 FEBRUARY 1984. (1167)A

THE HELLENIC ANTICANCER INSTITUTE

invites applications for the post of

DIRECTOR

of its Research Center coprising Biochemistry, Biology, Cell Physiology and Immunology Departments.

Candidates must have proven experience in Cancer Research and ability to develop their own research projects.

Applications should be accompanied by a detailed curriculum vitae, a summary of proposed research projects and the names of three referees and should reach: The Hellenic Anticancer Institute, 171 Alexandras Ave., Athens, Greece, not later than February 29th 1984. The appointment originally for three years will be renewable and will carry a Greek University proffessorial salary. (W737)A

Universiteit van Amsterdam

professor of biochemistry (m/f)

Applications are invited for a full-time position as Professor in the Interfaculty Department of Biochemistry, University of Amsterdam. There are seven other full-time professors in the Department.

The successful applicant should undertake, co-ordinate and stimulate research in biochemistry, preferably with regard to integrated biological systems, and will be required to teach biochemistry to undergraduate and postgraduate students. In addition, the successful applicant will have certain administrative duties connected with the organisation of the Department and the Faculty.

He or she will be expected to speak Dutch or to master Dutch within two years of appointment.

Gross salary depends on age and experience and ranges from Dfl. 6.561,- to Dfl. 9.283,- per month. (Dutch Civil Servants Code).

Further particulars can be obtained from the Secretary of the Appointment Committee, Prof. Dr. K. van Dam, B.C.P. Jansen Instituut, Plantage Muidergracht 12, 1018 TV Amsterdam, The Netherlands, telephone 020-5222125.

Applications, quoting number 7525, accompanied by an extensive curriculum vitae, a list of publications, a description of present research interests and the names of at least three referees, should be sent within four weeks to: The Chairman of the Appointment Committee, Professor Th.J. de Boer, Laboratory of Organic Chemistry, Nieuwe Achtergracht 129, 1018 WS Amsterdam, The Netherlands.

Suggestions for possible candidates may be sent to the Committee.

Women in particular are invited to apply.

(W734)A

KING FAISAL UNIVERSITY
Al-Hasa, Saudi Arabia

College of Veterinary Medicine and Animal Resources

invites applications for faculty positions in the following disciplines:

- **Vet. Deficiency Diseases and Clinical Lab. Diagnosis**
- **Endocrinology**
- **Vet. Microbiology**
- **Vet. Gynaecology/Obst.**
- **Food Hygiene and Meat Inspection**
- **Vet. Public Health/ Food Hygiene and Zoonosis (milk products hygiene)**
- **Vet. Pathology**

Requirements: Doctorate for Professors, Associate and Assistant Professors. MSc degree for Lecturers. Publications in professional journals, minimum of 2 years teaching experience for Asst. Professors and 4 years for Associate Professors and Professors. **Applicants must be fluent in both Arabic and English.** All faculty members are expected to conduct research in their area of interest.

Salaries are highly competitive. Contracts are for one year renewable.

Benefits include free furnished housing or housing allowance, annual return air tickets for a family of four, 60 days paid annual leave, generous luggage overweight allowance, educational allowance for children. No Saudi tax.

Closing date for applications: 9 March 1984. (W745)A

Application forms can be obtained from either of the following addresses, stating clearly the position applied for:

Dean, College of Veterinary Medicine and Animal Resources

BIOMEDICAL RESEARCH OPPORTUNITIES
NATIONAL INSTITUTES OF HEALTH

The Intramural Research Division of the National Institute of Arthritis, Diabetes, and Digestive and Kidney Diseases (NIADDK), has openings for highly qualified applicants in many exciting areas of biomedical research. NIADDK, one of 11 Institutes comprising the National Institutes of Health (NIH), located 20 minutes from Washington, D.C., in suburban Maryland, offers a unique research opportunity for scientists from both the U.S. and abroad. The NIH commitment to full-time research and its academic atmosphere together with state-of-the-art instrumentation and extensive interaction among the 2500 doctoral-level scientists at the NIH constitute a biomedical research environment that is unequalled elsewhere.

The majority of the 350 positions at NIADDK are filled by postdoctoral and sabbatical-leave scientists for periods of up to several years. For further information about specific research in areas listed below, send inquiries to: Recruitment Program, Dr. Jesse Roth, Director of Intramural Research, NIADDK, National Institutes of Health, Bldg. 10, Rm. 9N-222, Bethesda, MD 20205.

- Gene expression
- Nucleic acid and chromatin structure
- Molecular genetics and recombinant DNA
- DNA and RNA replication
- Membrane biology/cell organelles
- Transport phenomena
- Hormones
- Enzymology
- Receptors
- Development and differentiation
- Protein structure and function
- Biophysics
- Mathematical biology
- Chemistry (all branches)
- Pharmacology
- Immunology
- Molecular mechanisms of disease
- Intercellular communication
- Neurobiology

NIH is an Equal Opportunity Employer

(NW276)A

SOUTH AFRICAN INSTITUTE FOR MEDICAL RESEARCH

SCIENCE GRADUATE: MICROBIOLOGY

We require the services of a Science Graduate (MSc or PhD) in the field of medical microbiology, with a special interest in antibiotics. The applicant should preferably be experienced in the techniques of susceptibility tests and antibiotic assays, but any suitably qualified person will be considered. The appointee will be expected to supervise an antibiotics reference laboratory and to participate in its research programmes..

We offer a competitive salary plus annual service bonus, housing subsidy, subsidised medical aid, Pension Fund and 30 days leave per annum.

Address applications, including curriculum vitae, to: Head Personnel Services, SAIMR, PO Box 1038, Johannesburg, 2000, Republic of South Africa.

(W742)A

TRANSLATOR/EDITOR

We are leading translation company with over 25 years' experience in the pharmaco-medical field. We need to increase our output capacity and are looking for a person with suitable qualifications and/or experience, English mother tongue and sound knowledge of German to join our team, working in an informal and stimulating environment. The work involves processing translations in all branches of medicine and pharmacology, including research reports, manufacturing specifications and published literature.

Salary according to qualifications and experience, subject to annual review, plus sundry benefits.

Apply in writing to: (1188)A

Dr A.M.A. Mincer, Chief Editor
AD — EX (TRANSLATIONS) LTD
P.O. Box 428, 296 Kingston Road, London SW20 8LZ

SHEFFIELD HEALTH AUTHORITY
MEDICAL LABORATORY SCIENTIFIC OFFICER

To be based in the Department of Haematology at the Royal Hallamshire Hospital. Candidates must be qualified to HNC level preferably in Haematology. This research post is tenable for 1 year commencing as soon as possible. The successful applicant will be involved in a study of the effects of fish-oils on red cell deformability.

Salary Scale: £5,491 £5,696, £6,144, £6,263, £6,436, £6,626, £6,851, £7,098, £7,306, £7,510, £7,747.

For further information contact Dr. F. E. Preston/Dr. M. Greaves, Telephone Sheffield (0742) 26484, extension 2122. Application forms are available from the Personnel Department, Westbrook House, Sharrow Vale Road, Sheffield S11 8EU. Telephone 686911 extension 145. Completed application forms should be returned no later than 23rd February 1984. (1173)A

UNIVERSITY OF BRISTOL

POST-DOCTORAL RESEARCH ON THEORY OF MOLECULAR PHOTODISSOCIATION PROCESSES

The experimental and theoretical study of molecular photo-dissociation processes forms one of the fastest developing research areas of chemical physics. Applications are invited for a post-doctoral research position to work on the theory of these processes. The research project will involve the development of fundamental theory as well as the running and modification of large computer programs. Experience in molecular collision theory, spectroscopy or large scale computational work will be an advantage.

Applications for the position should be sent to: Dr G G Balint-Kurti, School of Chemistry, Bristol University, Bristol BS8 1TS.

Applications should include the names of two referees. Further information about the position will be sent upon request. (1146)A

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified men and women for appointment to the following position:

RESEARCH SCHOOL OF PHYSICAL SCIENCES RESEARCH FELLOW IN ASTROPHYSICS

The Mount Stromlo and Sidin Spring Observatories (Director Professor D S Mathewson) operat seven telescopes on Mount Stromlo and on Siding Spring Mountain with a wide variety of advanced in struments for spectroscopy, photo metry, polarimetry and direc imaging. A 2.3 metre advance technology telescope will come int operation at Siding Spring in 1984 The main lines of research are o evolutionary problems in stars, th interstellar medium, globula clusters, galactic structure, th Magellanic Clouds, external galaxie and radio sources. Universit astronomers have access to th Anglo-Australian Telescope, the 6 metre radio telescopes at Parke NSW and Tidbinbilla, and th synthesis telescopes of the Universit of Sydney. A VAS 11/780 compute and a PDS micro-photometer ar available for data reduction an image processing: there is also a lin with the University's UNIVAC facility.

Appointment is available fron mid-1984. Closing date: 15 Marc 1984.

Conditions of apointment: Salar will be in accordance wit qualifications and experience withi the range: Research Fellow $A23,39 — $A30,734 pa. Current exchang rate is $A1 = UK63p.

Appointment as Research Fello normally up to three years with th possibility of extension to maximu of five years.

Grants are provided towards trav and removal. Assistance towar housing is given to an appointee fro outside Canberra. Eligible appoi tees will be required to join the Supe annuation Scheme for Australia Universities. The University reserv the right not to make an appointmer or to make an appointment b invitation at any time.

Prospective applicants shoul write to the Registrar of the Unive sity, GPO Box 4, Canberra, AC 2601, Australia, or to the Associatio of Commonwealth Universitie (Appts), 36 Gordon Square, Londo WC1H 0PF, for further particula before submitting applications.

(W744)A

POSTDOCTORAL Fellow — Endo crinology — Autoimmune endocrin disease group requires fellow wit experience in basic immunology cell biology to work in areas of in vitro antibody control, monoclon antibody production and antige purification. opportunity for inde pendent work and career develop ment. Two year position availabl Summer '84. Send cv to Dr T Davies, Division of Endocrinology The Mount Sinai School of Medicine One Gustave L Levy Place, Nev York, NY 10029. An Equal Opport unity Employer. (NW268)A

UNIVERSITY OF HONG KONG

HOSPITAL BIOCHEMIST
(Re-advertisement)

pplications are invited for a post of ospital Biochemist in the Clinical iochemistry Unit of the Hospital athology Services of the University.

Candidates should posses ppropriate professional qualifica-ons and have experience of hospital ochemistry and a background of search in related problems. The ccessful candidate will work in the linical Biochemistry Unit which ovides a chemical pathology rvice to the Queen Mary Hospital ıder the supervision of a Senior onsultant.

Annual salary (superannuable) is ı an 11 point scale: HK$135,780 — 7,100 (£12,344 — 20,645) (Sterling uivalent as at January 23, 1984). arting salary will depend on quali-cations and experience.

At current rate, salaries tax will not ceed 15% of gross income. ousing benefits at a rental of 7½% salary, children's education lowances, leave and medical nefits are provided.

Further particulars and plication forms may be obtained om the Association of ommonwealth Universities ppts), 36 Gordon Square, London C1H 0PF, or from the ppointments Unit, Secretary's ffice, University of Hong Kong, ong Kong. Closing date: 31 March 84. (W739)A

THE UNIVERSITY OF MANCHESTER/ ARESBURY LABORATORY

SYNCHROTRON RADIATION POST DOCTORAL POSTS IN X-RAY SPECTROSCOPY
Re-advertisement

pplications are invited for two sitions funded by SERC, tenable om as soon as possible for two years the first instance. One post is ncerned with research at the nchrotron Radiation Source at aresbury and the successful ndidate would be responsible for e development and commissioning a fluorescence detector facility on e X-Ray Spectroscopy Station on e Wiggler beam line. The second st is in connection with the recently tablished EXAFS service at aresbury, which is designed to hance the applications of EXAFS chniques to the study of chemical d biochemical systems. Applicants e expected to hold a PhD in ysics, Chemistry, or a Biological ience. Experience in strumentation and/or computation ould be advantageous. Salary range £7,190 — £11,615 uperannuation).

Applications, with full CV and the mes of two referees, to either Dr D Garner, Chemistry Department, niversity of Manchester, Manchester 13 9PL or Dr S S Hasnain, aresbury Laboratory, Warrington A4 4AD by February 21st, 1984. (1180)A

SOUTH MANCHESTER AUTHORITY CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE PATERSON LABORATORIES

A vacancy exists at postdoctoral level within a group devoted to the study of the epithelial cells of a variety of tissues. The interests of the group centre on the cellular organisation of proliferation in a wide range of surface epithelia (skin, oral mucosa and gastrointerestinal tract), the mechanisms involved in the control of cell proliferative and differentiation and the malfunction of these controls that result in cancer and other proliferative disorders. We are particularly concerned in bringing new scientific interests into the group and add to the wide-ranging approaches concerned in bringing new scientific interests into the group and add to the wide-ranging approaches that are currently used. Fields of particular interest include epithelial cell culture, flow cytometry, monoclonal antibodies and molecular biology. The successful candidate would be able to develop his own area of study within the overall framework and under the general guidance of Dr C S Potten the group leader. Potential projects could include the use of epidermal cultures to analyse control factors, the indentification of early differentiation events in epithelial tissues and their relationship to carcinogen target cells.

The work is supported by grants from the Cancer Research Campaign and the position would be tenable for three years with the possibility of renewal.

Applications should be made to Dr C S Potten, The Paterson Laboratories, Christie Hospital and Holt Radium Institute, Wilmslow Road, Manchester M20 9BX, and include a curriculum vitae, the names of two academic referees and outline of interests in connection with the work described above. (1184)A

ASSISTANT PROFESSOR MOLECULAR BIOLOGY

The Department of Microbiology, Louisiana State University (LSU), Baton Rouge, LA invites applications for an anticipated tenure-track position at the Assistant Professor level.

Candidates must have post-doctoral experienced and strong credentials in molecular biology. Individuals with an interest in biotechnology are especially encouraged to apply. Preference will be given to those with experience in recombinant DNA techniques.

Send curriculum vitae, a description of future research interests, and a list of three references by April 1, 1984, to: Dr M D Socolofsky, Chairman, Department of Microbiology, 508 Life Sciences Building, Louisiana State University, Baton Rouge, LA 70803. LSU is an Equal Opportunity/ Affirmative Action Employer.

Anticipated Hire Date: Fall 1984. (NW284)A

Cranfield
Silsoe College

A new Chair in support of the food production industry

Applications are invited for a new Chair at Silsoe College, Cranfield Institute of Technology. This Chair will be the first appointment leading to the establishment of a strong, research-based group in support of the food industry in Britain.

Preference will be given to applicants who are recognised authorities in a particular field of science relevant to food production. The successful candidate will be capable of forming and leading a multidisciplinary team undertaking a balance of fundamental and applied research supported by industrial and other food sector sponsors.

The programme of work may be concerned with the development of a better understanding of the nature and properties of food raw materials and their inter-relationships. Work may also be undertaken on the synthesis of more cost-effective food manufacturing processes through improved engineering or food design.

For further particulars please contact: The Personnel Department, Cranfield Institute of Technology, Cranfield, Bedford MK43 0AL. Telephone: Bedford (0234) 750111 ext 3336.

Closing date for applications: 12 March 1984. (1153)A

UNIVERSITY COLLEGE DUBLIN

Applications are invited by the Governing Body of the College for the following full-time statutory appointment:

PROFESSORSHIP OF AGRICULTURAL ZOOLOGY

Prior to application, further information (including application procedure) may be obtained from the Secretary and Bursar, University College, Belfield, Dublin 4. Telephone enquiries: 693244 ext 431.

The closing date for receipt of completed applications is Thursday, 8th March 1984. (1150)A

YOU'VE GOT A BRIGHT IDEA

for new biological or chemical compounds.

WE HAVE THE CAPITAL

to develop new drugs.

We are not a pharmaceutical firm but a Swiss-based, independant financial group which is prepared to let you participate in a capital venture for the exploitation of your project.

Our objective: the development of new biological or chemical products having previous pharmalogical screening up to the stage of clinical tolerance and efficacy required to permit licensing negotiations.

To obtain all the information required for initial selection, please write in English, French or German to:
DEBIOPHARM S.A. Petit-Chêne 38 - 1001 LAUSANNE (Switzerland). (W732)A

THE INTERNATIONAL CENTRE OF INSECT PHYSIOLOGY AND ECOLOGY
P.O. BOX 30772, NAIROBI, KENYA

REF: S7/ ADVERT/ 20/ 47920th January 1984

DEPUTY DIRECTOR

(REF: SCI/ 83/ 7): Readvertisement

The ICIPE is an international institution headquartered in Nairobi, Kenya. It undertakes advanced research in insect science and post management, and offers high-level training to insect scientists and technologists from Africa and other developing countries. It has 40 senior scientists; and is funded by a consortium of donors comprising United Nations and international bodies, governmental aid agencies, and private foundations.

Applications are invited from highly qualified scientists and widely experienced reserach managers for the senior research management position of DEPUTY DIRECTOR at the ICIPE.

The Deputy Director reports directly to the Director of the Centre, and in his absence, acts for him. He will, in addition, have overall responsibility for the Research Division of the ICIPE, which includes the research programmes, research support units, and technical support services (including field station facilities); and maintain close liaison with supportive Divisions within the ICIPE (on Administration, Finance, and Communication and Training). The successful candidate will be a person with a solid research background in insect science or pest management or plant protection, he will have had considerable experience in science policy matters and research management; and he will be a successful internationalist able to work in an African environment. A more detailed job description will be sent to qualified candidates.

The renumeration package will be competitive, and will reflect the vital importance of this position within the ICIPE. Applications, giving updated curriculum vitae and addresses of three referees should be addressed (in confidence) to:

The Director,
ICIPE,
P.O. Box 30772,
NAIROBI, Kenya

Closing Date: 31st March 1984. (W735)A

THE UNIVERSITY OF ADELAIDE

invites applications from both men and women for the following position:

RESEARCH ASSOCIATE IN MICROBIOLOGY AND IMMUNOLOGY

To work in a small group as a molecular biologist on specific surface components of E Coli and Salmonella. The project requires the cloning and analysis of genes relevant to outer membrane proteins and lipopolysaccharide followed by genetic and molecular analysis. Our interest is in using these techniques to analyse the function and regulation of surface proteins, and also to determine the molecular changes involved in the evolution of the extreme variability of Salmonella surface polysaccarides: the appointee could be involved in one or both of these areas. The Department has a strong base in molecular genetics including several other interacting projects involving cloning and sequencing techniques as tools, and is well equipped for this type of work.

Applicants should hold a PhD in the area of molecular genetics and preferably have one to two years relevant postdoctoral experience. The position which is funded by the ARGS is available from January 1984 for one year in the first instance. There is a commitment by the ARGS to provide funds for the position for two years.

Further information concerning the details of the position may be obtained from Dr. P. Reeves of the Department of Microbiology and Immunology (08) 228 5436.

Further information about the general conditions of all appointments may be obtained from the Senior Assistant Registrar (Personnel) at the University.

Salary per annum: $A20164 x 5 — $23100.

Applications, in duplicate, quote reference number X3930 and giving full personal particulars (including citizenship), details of academic qualifications and names and addresses of three referees, should reach the Senior Assistant Registrar (Personnel) at the University of Adelaide, GPO Box 498, Adelaide, South Australia 5001 (telex: UNIVAD AA89141), as soon as possible and not later than 9 March 1984.

The University reserves the right not to make an appointment or to appoint by invitation. (W738)A

MRC CELL BIOPHYSICS UNIT

Applications are invited for a three-year, short-term

POSTDOCTORAL RESEARCH POSITION

available from 1 October 1984, to work on the molecular biology of dedifferentiation and morphogenesis in amphibian limb regeneration. This position is part of a collaboration between Dr Jeremy Brockes and Dr Roger Patient involving the analysis of gene expression in relation to these phenomena. Recent studies have led to the development of monoclonal antibodies as markers for blastemal and differentiated cell types both in vivo and in vitro; further studies will also involve the application of nucleic acid methodology. Experience in recombinant DNA techniques would be an advantage.

The salary will be on the scale £8,376 — £11,896 inclusive per annum; MRC superannuation scheme.

Applications with the names and addresses of two referees should be sent by 29 February 1984 to Mr D M Drummie, MRC Cell Biophysics Unit, King's College London, 26-29 Drury Lane, London WC2B 5RL; telephone 01-836 8851. (1159)A

UNIVERSITY OF IOWA

DEPARTMENT OF ZOOLOGY

POSTDOCTORAL POSITIONS

available to study the molecular and developmental biology of cell motility and chemotaxis in the cellular slime mold Dictyostelium discoideum.

Please send curriculum vitae and names of three references to: Dr David R Soll, Department of Zoology, University of Iowa, Iowa City, IA 52242. The University of Iowa is an Equal Opportunity/Affirmative Action Employer. (NW283)A

UNIVERSITY OF WARWICK

POSTDOCTORAL RESEARCH FELLOW IN MOLECULAR VIROLOGY

In the Department of Biological Sciences to work on a project funded by the European Economic Community. The work will be concerned with the application of recombinant DNA techniques to the study of Rotaviruses. Salary will be on the Research IA scale: £7,190 to £11,615 pa. The position is available from 1st April 1984 for an initial period of two years. Further information can be obtained by telephoning Dr M A McCrae on Coventry (0203) 24011 ext 6024.

Applicants should send a CV with the names and addresses of two referees to the Executive Officer, Department of Biological Sciences, University of Warwick, Coventry CV4 7AL, quoting reference MAM/NAR. Closing date 27th February, 1984. (1152)A

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF PATHOLOGY

UNIVERSITY LECTURER OR UNIVERSITY DEMONSTRATOR IN IMMUNOLOGY

Applications are invited from Immunologists or from Molecular Biologists with an interest in Immunology for a University Lectureship or University Demonstratorship, the appointment to commence as soon as possible and preferably not later than 1 October 1984. Candidates should hold a PhD degree, or the equivalent, and have several years post-doctoral experience in Immunology. The apointment will be for three years, with the possibility, for a University Lecturer of re-appointment to the retiring age or, for a University Demonstrator, re-appointment for a further two years.

The pensionable scale of stipends, for persons not ordinarily resident in college, are for a University lecturer £9,875 a year, rising by eleven annual increments to £15,085 and for a University Demonstrator £7,630 a year, rising by four annual increments to £9,425. There is no grade of Senior lecturer.

Further information about the duties and conditions of appointment may be obtained from the Secretary of the Appointments Committee for the Faculty of Biology 'B', 19 Trumpington Street, Cambridge CB2 1QA, to whom applications (12 copies), including a curriculum vitae, list of publications and the names of not more than three referees, should be sent so as to reach him not later than 1 April 1984. (1157)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE

(University of London)

DEPARTMENT OF ANATOMY

Applications are invited for the post of

LECTURER/SENIOR LECTURER

Applicants must have experience in both the teaching and examination of the anatomical sciences. The successful candidate will be required to develop the teaching of histology and will be encouraged to continue/develop his/her personal research programme. Departmental research interests include, Biomechanics, Embryology, Ergonomics, Microcirculation and the use of computers in teaching morphology.

Post available from 1 April 1984. Salary on scale £7,190 — £14,125 (Lecturer) or £13,515 — £16,925 (Senior Lecturer) plus £1,180 London Allowance, with superannuation benefits.

Further particulars available from the School Office, RFHSM, Rowland Hill Street, London NW3 2PF (01-794 0500 ext 4262) to which applications (7 copies of curriculum vitae, including the names and addresses of two referees) should be sent by 2 March 1984. Visits to the department can be arranged by appointment with the Departmental Secretary. Tel: 01-794 0500 ext 4355. (1183)A

COMMONWEALTH AGRICULTURAL BUREAUX

SCIENTIFIC INFORMATION OFFICER

at the COMMONWEALTH INSTITUTE OF PARASITOLOGY

Duties: Preparing abstracts in English for **Helminthological Abstracts** and **Protozoological Abstracts** which cover world scientific literature in these fields, indexing, and answering scientific inquiries.

Qualifications: A degree in zoological science or related subject, plus a reading knowledge of at least one European language (German preferred) and the ability to write good English. Applicants must be able to render the content of scientific publications into concise, accurate and readable abstracts. It is expected that the successful candidate will wish to make a career in the field of scientific information rather than research.

Salary: In the scales £5,682 – £7,765 pa, £7,149 – £9,561 pa. Starting salary according to qualifications and experience.

Applications forms and further particulars from: Commonwealth Institute of Parasitology, 395A, Hatfield Road, St. Albans Herts AL4 0XU. Tel: 0727 33151

Closing date for applications 1st March 1984. (1161)A

DRUG DESIGN AND DEVELOPMENT

METABOLISM AND KINETICS

Pfizer Central Research is part of a multi-national organisation engaged in the research, development, manufacture and marketing of a wide range of human and animal health products.

Currently over 500 scientists and supporting staff work at Sandwich in modern, well equipped laboratories. An additional 70,000 sq ft of laboratory and office space is currently being built and will be ready for occupation in the summer.

At that time we shall need an additional high calibre PhD to join our Drug Metabolism Department. We are seeking a chemist/biochemist or analytical chemist who is completing his/her PhD research project in metabolic biochemistry, pharmacokinetics or bioanalysis this year, or someone with up to 3 years' post-doctoral experience in these areas.

The function of drug metabolism is to provide information on the absorption, distribution, metabolism and excretion of drugs in laboratory animals and man. Firstly, so that a better understanding of the mode of action and toxicology can be achieved and, secondly, to aid in the design of drugs with a more desirable pharmacokinetic profile. The department has a major commitment to the application of drug metabolism to the drug discovery process and the person we seek will be self-motivated and enjoy the challenge of being responsible for the development of assay methods and suitable animal models for the study of the kinetics of potential new drugs.

Pfizer

This exciting new appointment offers a highly competitive basic salary plus a bonus related to personal performance. We have a thriving sports and social club with first-class facilities. We also offer generous help with relocation expenses.

If you are interested in this appointment, please send your cv, in confidence, to: D. W. Sells, Personnel Manager, Pfizer Central Research, Ramsgate Road, Sandwich Kent CT13 9NJ. (1194)A

1979

MRC CLINICAL RESEARCH CENTRE
(Northwick Park Hospital)
Watford Road, Harrow,
Middx HA1 3UJ

APPLIED IMMUNO-CHEMISTRY RESEARCH GROUP

Applications are invited from science or medical graduates for a 3 year postdoctoral position to participate in studies of the structure and function of glycoprotein and glycolipid markers of human tumours and leukemic cells detected by monoclonal antibodies. The work will be carried out in a research group (head of group Dr Ten Feizi) which is well equipped for immunochemistry and carbohydrate biochemistry. A strong background in biochemistry is desirable.

Salary scales are related to those for university non-clinical academic staff and the NHS for clinically qualified candidates. Salary on appointment will depend on age and experience.

Application forms and further details may be obtained by writing to Miss J Cottam, Personnel Dept, quoting ref 108/1/3784. Closing date for applications 2nd March 1984. (1162)A

PHYSICS

Research positions. Applications are invited for positions in the following areas: nuclear and accelerator based physics: nuclear structure, nuclear astrophysics. PIXE with a proton microprobe and applications of nuclear techniques to materials analysis. Solid state and applied physics: magnetic inspection techniques for gas pipelines, effects of stress on the magnetisation of steels, theory of ferromagnetic hysteresis, nuclear magnetic and quadrupole resonance, solid state theory, fast ion transport, surface diffusion, thin films and ferroelectrics, physics at millikelvin temperatures, phase transitions, positron and positronium interactions in solids, metals at high magnetic fields, ultrasonics. Astronomy and astrophysics: galactic structure and evolution, general relativity, relativistic astrophysics, radio astrophysics, stellar structure and evolution, star formation and the interstellar medium. Candidates of either sex are equally encouraged to apply. Salary dependent on qualifications.

Please apply, enclosing a curriculum vitae and the names of three referees, to: Dr M J Stott, Head, Department of Physics, Queen's University, Kingston, Ontario K7L 3N6. (NW281)A

UNIVERSITY OF LONDON

COURTAULD CHAIR OF ANIMAL HEALTH AND PRODUCTION AT THE ROYAL VETERINARY COLLEGE

The Senate invite applications for the above Chair which will become vacant from 1 October on the retirement of Professor J A Laing.

The Chair has previously been entitled the Courtauld Chair of Animal Husbandry and Veterinary Hygiene and the title has been changed to reflect a change of emphasis which has taken place.

Candidates should possess a registrable veterinary qualification and have a specialised knowledge and active research interest in one or more aspects of the subject.

Salary within the Professorial range. The current minimum is £18,461 per annum including London Allowance.

Intending applicants should obtain further particulars from the Academic Registrar (N), University of London, Malet Street, London WC1E 7HU, before submitting applications (10 copies). Closing Date for applications: 28 March 1984. (1177)A

INSTITUTE OF CANCER RESEARCH

Fulham Road, London SW3

A post-doctoral vacancy exists in the Chemical Carcinogenesis Section for a scientist with experience of recombinant DNA research to join a team working on the molecular basis of mutation and transformation of mammalian cells by carcinogens. The scientist appointed will have as close colleagues members of both the Chemical Carcinogenesis and Cell and Molecular Biology Sections of the Institute, and will be encouraged to develop his or her own ideas in relation to the overall problem. The appointment will be for a minimum of 3 years, with salary appropriate to age and experience within the scale £7,630 — £10,250 p.a., plus London Allowance of £1,186 p.a. and superannuation (USS).

Applications with full career details in duplicate and the names of two referees should be sent to the Personnel Officer, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref. 300/G/41. Further details of the post may be obtained by contacting Professor P. Brookes (Tel: 02404-2326). (1169)A

KING FAISAL UNIVERSITY
Al-Hasa, Saudi Arabia
College of Agriculture and Food Sciences

invites applications for faculty positions in the following disciplines:

MEN'S COLLEGE
- **Agricultural Climatology/Water Resources**
- **Farm Power and Machinery**
- **Agricultural Engineering**
- **Rural Sociology**
- **Horticulture, Crop Physiology and Genetics**
- **Poultry and Animal Breeding**
- **Meat Science and Technology**
- **Fish Sciences**
- **Analytical Chemistry (preferably Computer-Aided Chemistry)**

WOMEN'S SECTION
- **Child Development and Family Life**
- **Home Management and Family Finance**
- **General and Organic Chemistry**

APPLICANTS MUST BE FLUENT IN BOTH ARABIC AND ENGLISH.

Requirements: PhD for Assistant and Associate Professors. Master's degree for Lecturers. Publications and minimum of 2 years teaching experience for Asst. Professors and 4 years for Associate Professors.

Salaries are highly competitive. Contracts are for one year renewable.

Benefits include free furnished housing or housing allowance, annual return air tickets for a family of four, 60 days paid annual leave, generous luggage overweight allowance, educational allowance for children. No Saudi tax.

Closing date for applications: 9 March 1984. (W746)A

Application forms can be obtained from either of the following addresses, stating clearly the position applied for:

Dean, College of Agriculture and Food Sciences

c/o UK Recruiting Office

MICROBIAL BIOCHEMIST/ PHYSIOLOGIST

A challenging career opportunity is available for a Microbial Biochemist/Physiologist in the biotechnical group at the Celanese Chemical Company Technical Center located in Corpus Christi, Texas.

The successful applicant will join a team of dedicated scientists engaged in developing biotechnology-based processes for the production of a variety of chemicals.

The position requirements are as follows:

- **PhD in Biochemistry or Microbiology**
- **Postdoctoral experience in the area of microbial metabolism or biochemistry**
- **Experience with the genetic manipulation of microorganisms is also desirable.**

This position requires participation in ongoing research programs as well as innovative thinking leading to new programs.

Interested candidates should forward a résumé with salary history in confidence to:

Personnel Supervisor
Celanese Chemical Company Technical Center
P.O. Box 9077
Corpus Christi, Texas 78469

equal opportunity employer m/f

(NW273)A

CELANESE®
CHEMICAL COMPANY, INC.

PROTEIN BIOCHEMIST

A senior biochemist is required to join a team working on scrapie and the related unconventional slow infections of the CNS. The appointee will be expected to develop and lead an innovative research programme to characterise (a) the infectious unit of scrapie (b) a gene product controlling the disease (c) cerebral amyloid and (d) scrapie-associated fibrils.

Applicants should have a good honours degree in chemistry or biochemistry and a PhD or the equivalent. A considerable proven research record in protein biochemistry is essential, proferably with experience in the analysis of hydrophobic proteins. The appointment will be as Principal Scientific Officer with salary in the range £11,343 – £14,931.

Applications giving full curriculum vitae and names of two referees to The Secretary, AFRC MRC Neuropathogenesis Unit, West Mains Rd., Edinburgh EH9 3JF. (1176)A

UNIVERSITY OF NOTTINGHAM

SCHOOL OF AGRICULTURE

RESEARCH ASSISTANT IN REPRODUCTIVE PHYSIOLOGY

A post-doctoral Research Assistant is required for a period of 18 months to study the use of milk temperature measurements as an aid to oestrus detection in dairy cattle. Applicants should have a higher degree i Animal Physiology, or a relate subject, and should have computin experience.

Application, including a full c and names and addresses of tw referees should be submitted to Pro G E Lamming, University o Nottingham School of Agriculture Sutton Bonington, Loughborough Leics LE12 5RD from whom furth written details of the post can b obtained. (1187)A

An der Formal – und Naturwissenschaftlichen Fakultät der Universität Wien ist die Planstelle eines Ordentlichen Universitätsprofessors für

BIOSTRATIGRAPHIE

zu besetzen.

Dar Ordinariat hat in Ergänzung der vorhandenen Forschungs – und Lehreinrichtungen die Biostratigraphie in Forschung und Lehre (im Ausmaß des Studienplanes der Studienrichtung Erdwissenschaften für das Diplom – und das Doktoratsstudium) zu vertreten.

Voraussetzungen für die Bewerbung sind: Habilitation oder eine andere, gleichwertige wissenschaftliche Qualifikation; Publikationstätigkeit in biostratigraphischer Richtung; internationale Erfahrung und Mitarbeit an fachspezifischen Projekten.

Die Bewerbungen mit den üblichen Unterlagen (Lebenslauf unter besonderer Berücksichtigung des wissenschaftlichen Werdeganges, Publikationsliste, Angaben zur bisherigen Lehr – und Forschungstätigkeit, sowie geplante zukünftige Forschungsrichtung) sind bis zum *15 April 1984* an das Dekanat der Formal – und Naturwissenschaftlichen Fakultät der Universität Wien, A-1010 Wien, Dr. Karl Lueger Ring 1 erbeten." (W743)A

DURHAM UNIVERSITY LECTURESHIP IN PHYSICS

Applications are invited for a Lectureship in Physics tenable from 1 October 1984 under the SERC Special Replacement Schme to enable the University to appoint an outstanding young researcher to a tenured post. The successful applicant will be expected to contribute to undergraduate and postgraduate teaching, particularly in the field of Solid State Physics, and to become actively involved in experimental research on Magnetism for which excellent facilities exist.

Salary on the scale £7,190 – £14,125 with superannuation.

Applications (3 copies) naming three referees should be sent by 29 February 1984 to the Registrar, Science Laboratories, South Road, Durham DH1 3 LE, from whom particulars may be obtained.

(1156)A

CHAIRMAN

DEPARTMENT OF ANATOMY

Applications are invited for th position of Professor and Chairman Department of Anatomy, Schools o Medicine and Dentistry, Universit of Alabama in Birmingham. We ar seeking candidates with research an teaching experience, leadershi qualities, and administrative skills This department has teachin responsibilities for graduate student in anatomy, medical, dental an other students.

Please submit applications and curriculum vitae to: Antonietta I Hyche, Administrative Officer University of Alabama School o Medicine, Dean's Office – ME 306, Birmingham, Alabama 35294 An Equal Opportunity/Affirmativ Action Employer. (NW263)A

An den
MAX-PLANCK-INSTITUTEN
in Martinsried/München

werden im Rahmen einer Kooperation der Max-Planck-Institute für Biochemie und Psychiatrie mit dem Genzentrum an der Universität München und der Industrie zunächst auf folgenden Gebieten **gentechnologische Arbeitsgruppen** eingerichtet:

1. **Mikrosequenzierung** von Proteinen und biologisch aktiven Peptiden mit Schwerpunkt Gasphasensequenzierung.
2. **Molekulare Embryologie,** bevorzugt Frühentwicklung von Säugern.
3. **Transkription (Genexpression bei Eukaryonten):** Mechanismen und Kontrollen mit Betonung der Differenzierung.

Pro Arbeitsgruppe stehen ca. 150m^2 Nutzfläche, angemessene Mittel für wissenschaftliche und technische Assistenten, Geräte und laufenden Bedarf zur Verfügung. Die Anstellung der Gruppenleiter(innen) wird für die Dauer von 5 Jahren vereinbart; Bewerbungen mit einem tabellarischen Lebenslauf, einem Schriftenverzeichnis und einer Kurzdarstellung der bisherigen und der geplanten Arbeiten sind bis zum **15. März 1984** zu richten an die Geschäftsführende Leitung des Max-Planck-Instituts für Biochemie in 8033 Martinsried. (W740)A

UNIVERSITY OF STRATHCLYDE
Department of Pharmacy

LECTURESHIP

Applications are invited from graduates in Pharmacy for a Lectureship tenable in the Department of Pharmacy from 1 August 1984. The successful applicant will be expected to participate in a wide range of teaching in pharmaceutics with a preferred emphasis on pharmaceutical microbiology. Appropriate research experience would be an advantage.

Appointment on the national salary scale for Lecturers £7,190 — £14,125 per annum. USS benefit.

Application forms and further particulars (quote ref: 7/84) are available from the Academic Staff Office, University of Strathclyde, McCance Building, 16 Richmond Street, Glasgow G1 1XQ. Closing date for applications: 23 March 1984. (1191)A

WELSH NATIONAL
SCHOOL OF MEDICINE
(University of Wales)

DEPARTMENT OF CARDIOLOGY

POSTDOCTORAL
RESEARCH OFFICER

pplicants with experience in hysiology/pharmacology are ivited to apply for a 3-year post ubject to a probationary period) to in a small research team working on ontrol mechanisms in vascular nooth muscle, with particular ference to the role of endothelium. ndividual initiative will be couraged within this area.

Starting salary for suitably ualified candidates could be up to 3,530 on the Scale for University esearch and Analogous Staff Grade A.

Applications in the form of a rriculum vitae with names and ldresses of two referees should be nt to the Registrar and Secretary, elsh National School of Medicine, leath Park, Cardiff CF4 4XN uoting ref No C15/2/31) one onth from the date of appearance f this advertisement. Further formation from Dr Malcolm Lewis 222/755944 ext 2066 or 2058). (1182)A

CHAIRPERSON — Biochemistry. The Albert Einstein College of Medicine of Yeshiva University seeks a Chairperson for the Department of Biochemistry. Individuals with a commitment to research and a strong research record are invited to apply. The selected Chairperson will become a tenured professor and space and resources will be available to maintain and expand a high quality department. Interested candidates are requested to send cv's by May 1, 1984 to: E R Stanley, PhD, Associate Professor of Microbiology and Immunology, Chairman of Search Committee for Biochemistry, Albert Einstein College of Medicine, 1300 Morris Park Avenue, Bronx, New York 10461. An equal opportunity employer. (NW269)A

POSTDOCTORAL POSITION
IN PHYSICS

A postdoctoral position is available immediately at the Physics Department of Emory University. The research involves applications of biochemical and spectroscopic techniques to the study of metalloproteins. Recent doctorates in physical chemistry or biochemistry are invited to apply. Experience in protein purification is desirable.

Send résumé and two letters of recommendation to Dr B H Huynh, Physics Department, Emory University, Atlanta, GA 30322. Emory University is an Equal Opportunity/Affirmative-Action employer. (NW278)A

PAISLEY COLLEGE

A Scottish Central Institution

DEPARTMENT OF BIOLOGY

LECTURSHIP IN CELL BIOLOGY/GENETICS

The successful candidate will teach aspects of Cell Biology and Microbial Genetics on the BSc (Hons) Degree course in Biology. He/she will contribute to first and second year teaching and also to the Molecular Genetics and recombinant DNA Technology Units of the Honours year of the Biology Degree course and the Grad. I Biol. courses in Biochemistry and Microbiology.

Relevant qualifications as well as a special interest in Microbial Genetics are essential and recent research experience of recombinant DNA techniques would be preferred. Applicants will be expected to hold a research degree.

LECTURESHIP IN PHYSIOLOGY

This is a fixed term appointment running to 30th June, 1985.

The successful candidate will teach aspects of human and comparative animal physiology in the BSc Honours Degree course as well as contributing to Higher Certificate (day release) and HND (full-time) teaching.

Applicants should have a research degree and a qualifiction and special interest in Physiology. Recent research experience of modern immunological techniques would be an advantage.

SALARY SCALE LECTURER 'A' £8,313 — £13,125

Application forms and further particulars for the above two posts are available from the Personnel Officer, Paisley College of Technology, High Street, Paisley PA1 2BE (Tel: 041-887 1241 ext. 230). Closing date for applications is 27th February, 1984. (1175)A

UNIVERSITY OF STRATHCLYDE
Department of Applied Physics

TEMPORARY LECTURESHIP

Applications are invited for a Temporary Lectureship (tenable until 30 September 1986) from applied physicists, biophysicists and engineers. Applicants with industrial experience, eg on secondment, will be especially welcome.

The successful candidate will be expected to undertake varied teaching duties, and to join in one of the multi-disciplinary research activities of the Department: Photophysical Instrumentation, Environmental Physics, Renewable-Energy Technology, Superconducting Devices, and Population Ecology. Candidates should have experience in one of these areas.

Further details and application forms (quote 6/84) are available from Academic Staff Office, University of Strathclyde, McCance Building, 16 Richmond Street, Glasgow G1 1XQ. Closing date for applications: 28 February 1984. (1190)A

BIOTECHNOLOGISTS!

NEW SOUTH WALES GOVERNMENT
Growth and Development
Livestock Research Position
Agricultural Research Centre, Trangie

Position No Ag 84/ 13

A researcher is required to work in a multidisciplinary research team investigating the effect of selection for growth rate on total herd productivity in cattle. This is a major project of wide significance to the beef cattle industry and is well supported by field and laboratory facilities. Opportunities will also exist to undertake growth and development studies in sheep.

Salary: A$17,110 to A$30,119 p.a. depending on experience and qualifications.

Qualifications: Essential: A degree in Agricultural Science, Veterinary Science or equivalent.
Desirable: Post-graduate qualifications or considerable research experience related to the study of growth and development in animals.

Duties: The successful applicant will be required to initiate and undertake pen and field studies with the effect of selection for growth rate on growth and body composition in cattle. These studies will utilise cattle from high and low weight selection lines and a randomly bred control line established at Trangie. Experience in the areas of growth modelling, the problems in comparing genotypes of different mature size and techniques of carcase evaluation and good statistical background is desirable.

Inquiries: (02) 217 5264 (Dr. G. Robards) or (068) 8882 Manual 87 (Dr. D. Saville)

General: Some consideration will be given to payment of removal expenses, should an interstate or overseas applicant be successful, however expenses incurred in attending interview must be met by the applicant.

Applications: **Are to be submitted to the Personnel Officer (Recruitment), P.O. Box K220, Haymarket 2000, Australia.**

Equality of Employment Opportunity is Public Service Policy

Applications close 16th March 1984. (W741)A

UNIVERSITY
OF CAMBRIDGE

DEPARTMENT OF ANATOMY

POST-DOCTORAL
RESEARCH ASSISTANT

Applications are invited for a 3 year post-doctoral research appointment to investigate the neural and neuro-endocrine basis of maternal behaviour. The post is supported by ARC funds with salary starting in the range £7,630 to £9,875 depending on age and experience.

Applications in writing including full CV and names and addresses of two academic referees to Dr E B Keverne, Department of Anatomy, University of Cambridge, Cambridge CB2 3DY, as soon as possible. (1172)A

UNIVERSITY OF MANITOBA
DIVISION OF HUMAN GENETICS

MOLECULAR GENETICIST

The Division of Human Genetics of the Faculty of Medicine invites applications for a full time Assistant Professor to commence by July 1, 1984. Preference will be given to individuals with demonstrated research experience in molecular genetics using recombinant DNA technology on mammalian systems, particularly in the area of genome organization, control of gene expression or gene mapping. A PhD, postdoctoral training and potential for an independent career as an experimental scientist are prerequisites.

An interest in developing expertise and a desire to be an effective educator are desirable qualities. The position is open to both women and men. Both women and men are encourged to apply. In accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada.

For full consideration send a concise description of projected research goals and interests, names of at least 3 individuals for letters of reference, and a curriculum vitae to: Dr. P. J. McAlpine, Division of Human Genetics, Faculty of Medicine, University of Manitoba, 770 Bannatyne Avenue, Winnipeg, Manitoba, Canada R3E 0W3. Deadline for receipt of applications: March 1, 1983. (NW254)A

Queen's University, Department of Radiation Oncology

CAREER SCIENTIST POSITION

A position is available as a "Career Scientist" of the Ontario Cancer Treatment and Research Foundation at the Kingston Regional Centre, Department of Radiation Oncology, Queen's University.

The applicant must have an MD or PhD or equivalent, must have had post-doctoral training relevant to cancer research, and must be capable of independent and innovative investigative work in the field of cancer. The ability to collaborate with existing scientists involved in tumour biology, tumour immunology and experimental cancer therapy is essential. The position is associated with adjunct academic rank and is renewable depending on satisfactory progress.

In conformity with Canadian immigration policy, preference will be given to Canadian citizens or landed immigrants. Address inquiries, with curriculum vitae, and the names of three referees to:

Dr J.S. Lott, Director
Ontario Cancer Foundation
Kingston Clinic
King Street West
Kingston, Ontario
CANADA K7L 2V7

(NW272)A

THE KENNEDY INSTITUTE

A recently qualified

POST-DOCTORAL
SCIENTIST

is required (supported by a 3-year grant to Dr I Olsen and Dr Helen Muir FRS) to work in the Cell Enzymology Unit. A newly discovered process of lysosomal enzyme transfer which is of potential clinical importance is being investigated. Experience of cell fractionation and protein/membrane purification procedures would be an advantage.

Salary on the Universities Research and Analogous Staff scales depending on age. London Weighting paid in addition.

Applications with curriculum vitae and names of two referees to The General Secretary, The Mathilda and Terence Kennedy Institute of Rheumatology, Bute Gardens, London W6 7DW. (1192)A

GUY'S HOSPITAL

CYTOGENETICIST
— (BASIC GRADE
SCIENTIFIC OFFICER)

Applications are invited for the po of Basic Grade Cytogeneticist. T Centre provides a diagnost cytogenetics service, includi prenatal diagnosis to the SE Tham Region. Practical experience in cyt genetics would be an advantage, b graduates in Biology or Genet could be given training in this post

Salary: £6,723 — £9,391 pa (Depending on experience).

For further information and application form please contact t Personnel Officer, Guy's Hospit St Thomas Street, London SE1 9R Tel: 01-407 7600 ext 3471 quoting r P/3.

Closing date for completed app cations: 29th February 1984. (1193)A

UNIVERSITY OF ARIZONA

ASSISTANT/ASSOCIATE PROFESSOR

Microbiologist/Immunologist

Applications are being invited for several tenure track positions in the recently reorganized Department of Microbiology and Immunology at the Assistant or Associate Professor level, to begin summer-fall semester, 1984. Duties include teaching undergraduate students, medical students, and graduate students, and conducting an independent research program. Research interests should be within the broad area of microbiology/immunology. Individuals with a strong background in immunology, pathogenics, bacterial physiology, and virology are particularly being sought. The successful candidate must have a doctoral degree and a record of excellence and productivity in scholarly work. Postdoctoral experience is preferred.

Qualified applicants should send a résumé and arrange to have three letters of recommendation sent to Professor William Meinke, Search Committee Chairman, Department of Microbiology and Immunology, College of Medicine, University of Arizona, Health Sciences Center, Tucson, Arizona 85724. Complete applications should be received by April 1, 1984. The University of Arizona is an Equal Opportunity/Affirmative Action Employer. (NW279)A

PATHOLOGIST

he Institute for Cancer Research is eking a Pathologist to head a athology laboratory that will be a source for a variety of programs in velopmental biology and onco-gy. Applicants should be board rtified in anatomic pathology, nowledgable in morphologic athology, particularly of laboratory imals, with interest in colla-orative research. Independent search will be encouraged. Staff pointment.

Direct inquiries and submit idence of research achievements id curriculum vitae to: Chairman of ie Search Committee for athologist, c/o Personnel Dept, stitute for Cancer Research of the ox Chase Cancer Centre. 7701 rholme Avenue, Phila, PA 19111. n Affirmative Action Equal pportunity Employer.

(NW282)A

UNIVERSITY OF MAINE
DIATOMIST/LIMNOLOGIST

esearch Associate position starting March for research on effects of idic deposition on lakes in northern ew England. Work includes the entification and enumeration of atoms in sediment cores, computer alyses, and rigorous field work. pplicants should be skilled atomists, have a working owledge of limnology, and hold a D or a master's degree with levant post-degree experience. lary $15,000/annum; one year sition.

Applications must be received by February 1984.

Apply by letter and résumé; list ree references; send to Ronald B avis, Dept Botany & Plant Patho-gy, University of Maine*, Orono, aine, 04469, USA *An Affirmative ction/Equal Opportunity Employer.

(NW274)A

KING'S COLLEGE SCHOOL OF MEDICINE AND DENTISTRY
King's College London
Denmark Hill,
London SE5 8RX
RESEARCH ASSISTANT (MLSO)

pplications are invited for the post Research Assistant to work on the velopment of coagulation in-bitors in the Thrombosis Research nit. Candidates should be aduates in biochemistry or armacology, and preferably with me experience in protein purifica-n and/or enzymology.

Salary £6,533 — £7,168 per num.

Applications, naming two referees id quoting Ref: CT/R2, should be nt to the Secretary of the School at e above address by 23 February 84. (1163)A

BIOCHEMISTRY

Biotechnology firm is seeking a few outstanding research scientists.

B.S./M.S./Ph.D.

IMMUNOCHEMISTS. Successful candidates will have a proven track record of industrial development of homogenous enzyme immunoassay test kits. Ph.D. Salary range of $35-50K.

MOLECULAR BIOLOGISTS. Successful candidates will have proven expertise in nucleic acid replication, enzymology, and recombinant DNA technology. Ph.D. Salary range of $32-50K.

Microgenics offers a scientific challenge and equity participation with competitive salaries and fringe benefits. For immediate consideration, forward your resume in strict confidence to:

(NW275)A

UNIVERSITY OF LEICESTER
DEPARTMENT OF ASTRONOMY

POST-DOCTORAL RESEARCH APPOINTMENT

An SERC-supported Post-Doctoral Research post is available for work on the determination of the geoid from satellite altimetry data. The project is linked with the UK interest in satellite laser ranging, and is intended to assist UK participation in future satellite altimetry programmes. The person appointed will be based in Leicester, but will collaborate with workers in Oxford and at the Institute of Oceanographic Sciences.

Applicants should have an appropriate background in physics or mathematics and an interest in geophysics and geodesy. The post is tenable for three years at a starting salary up to £8,080. The appointment is to be taken up, if possible, on 1 April, 1984.

Applicants should send a curriculum vitae, together with any other relevant information, and should arrange for two referees to write in their support. Applications and references should be received by 2 March 1984 and should be addressed to Professor A J Meadows, Astronomy Department, The University, Leicester LE1 7RH, to whom any enquiries should also be directed.

(1181)A

MOLECULAR BIOLOGY

PROJECT SUPERVISOR (C-DNA)

The research manager of a pharmaceutical company, a world leader in its market, is looking for a project supervisor for its ***GENE - SPLICING UNIT.***

His primary task, working with a team of biologists, will be to set up a bank of ***EUKARYOTIC C-DNA.***

He will be a man or woman at least 28 years old, a D.Sc., agricultural expert, pharmacist, Ph.D., etc., with a successful background in a molecular biology laboratory.

Potential applications are vast, and this biologist's work will have almost immediately practical consequences.

The location is a leading French university town.

Please send your application to Jacques TIXIER with the reference 333 N. (NW748)A

jacques tixier s.a.

AVAS CONTACT

UNIVERSITY OF DUBLIN
Trinity College

CHAIR OF PHYSICS

This Chair, carrying the title 'Erasmus Smith's Chair of Natural and Experimental Philosophy (1724)' will fall vacant in 1984 when the present occupant and head of department, Professor Brian Henderson, leaves to take up another post.

The department is at present organised into the following research groupings:

(a) SURFACE PHYSICS;
(b) NUCLEAR INSTRUMENTATION;
(c) SOLID STATE SPECTROSCOPY;
(d) NON-CRYSTALLINE MATERIALS;
(e) LASER AND OPTICAL ELECTRONICS.

Applications are invited from theoretical physicists with relevant interests and from experimentalists: in present circumstances, applicants whose interests relate to solid state physics may be at some advantage.

Further particulars may be obtained from: G. H. H. Giltrap, Secretary to the College, Trinity College, Dublin 2, to whom formal application may be made, preferably not later than 17 February, 1984. (1164)A

WASHINGTON UNIVERSITY
SCHOOL OF MEDICINE
POSTDOCTORAL
RESEARCH FELLOW

Available immediately. Applications are invited for a 2-3 year post-doctoral research appointment in molecular biology/protein chemistry to investigate structure/function of oncogenes, growth factors, and transforming proteins.

Apply with curriculum vitae and two references to Dr Thomas F Deuel, Division of Hematology, Washington University School of Medicine, 216 S Kingshighway, St Louis, MO 63110. (NW271)A

JAPANESE BIOTECHNOLOGY STUDY TOUR

An in-depth series of site visits, conferences and seminars with some of Japan's leading industrial scientists and executives in biotechnology.

This exclusive study tour is designed to give western scientists and executives an opportunity to become acquainted with the Japanese marketing and research capacity. The mission will be led by Christopher G. Edwards, Editor in Chief of BIO/TECHNOLOGY, and organized by the Technology Transfer Institute. Visits will be conducted throughout Japan from March 31-April 15.

For further information, contact: Technology Transfer Institute — New York, One Penn Plaza, Suite 1411, 250 W. 34th St., New York, N.Y. 10119. 212-947-2648 telex 420057TTIUI. Attention: Mr. Hashizume. (NW174)C

WORKSHOP

EMBO INTERNATIONAL WORKSHOP
THE APPLICATION OF MOLECULAR BIOLOGY TO THE NERVOUS SYSTEM
Lady Margaret Hall, Oxford
September 23-25, 1984

Organisers: E.A. Barnard, M.R. Hanley, J.F. Jackson, Department of Biochemistry, Imperial College, London SW7 2AZ, UK

Topics: Approaches using molecular genetics and complementary molecular and immunological techniques applied to: receptors, ion channels, neurotransmitters, brain structures and neural development.

Investigators experienced in these areas have been invited to review current approaches and lead discussion periods, which will be extensive. The meeting will be in residential workshop format and will be limited to 65 participants.

Applications to attend should be sent, with a short statement of recent research work, to Professor E.A. Barnard (marking the envelope "EMBO Workshop").

A number of places are being reserved for younger postdoctoral workers interested in this field, and some funds are available for their support. The registration fee of £100 (payable on acceptance) will include full board and accommodation for four nights, conference dinner and reception. (1189)V

ASSISTANTSHIPS

UNIVERSITY
OF LIVERPOOL
DEPARTMENT OF GEOGRAPHY
Applications are invited for
POSTDOCTORAL SENIOR
RESEARCH
ASSISTANTSHIP

in the Department of Geography to work on an investigation of global cloud data archiving and analysis.

Applicants should hold a PhD in atmospheric science or physics and have considerable experience in computing. He or she must be able to undertake independent research; be prepared to attend international meetings and to collaborate with research scientists at the US Air Force Research Geophysics Laboratory in Massachusetts. Considerable experience has been established by this group. It is hoped the successful candidate will be able to draw upon developed techniques as well as contributing new ideas to the understanding of cloud observations from surface bases and satellites.

The project is financed on a year-by-year basis for two years from 1st March, 1984. The initial salary will be on the scale £7,190 — £8,530 per annum.

Applications, together with the names of three referees, should be received not later than 28 February, 1984, by The Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/222/N. (1179)P

THE MIDDLESEX
HOSPITAL MEDICAL
SCHOOL
(University of London)
RESEARCH
ASSISTANTSHIP IN
FREEZE-FRACTURE
STUDIES

Applications are invited for a post-doctoral research assistantship to investigate the fine structure of the myelinated nerve fibre using the freeze-fracture technique. It is desirable that applicants have some experience in the freeze-fracture technique but not necessarily in neurobiology. The post, tenable for two years, is funded by The Wellcome Trust. Starting salary according to age, qualifications and experience up to £9,267 per annum inclusive of London Allowance.

Applications together with curriculum vitae and the names of three referees should be sent to L M J G Harrison, Director, Reta Lila Weston Institute of Neurological Studies, The Middlesex Hospital Medical School, London W1N 8AA. (1186)P

ANNOUNCEMENT OF OPPORTUNITIES FOR THE SUPPORT OF RESEARCH AND DEVELOPMENT IN THE EUROPEAN COMMUNITY

Experimental action, 1984 to Stimulate the efficacy of Europe's scientific and technical potential

1. OBJECTIVES

The Commission of the European Communities has undertaken an experimental Stimulation Action designed to improve the efficacy of European research and development. This experimental action is intended to test various methods of support appropriate to the Community level, methods which are innovative by comparison with the range of available approaches which have been used by the Commission for several years in implementing its scientific and technical programmes.

2. AREAS AND ACTIVITIES SUPPORTED

The following may be supported:

- projects put forward jointly by teams of researchers or engineers from the various countries of the European Economic Community, and requiring collaboration — on a mono or multidisciplinary basis — between these teams (either in the public or private sector) in order to be brought to a successful conclusion;
- projects involving the secondment for relatively long periods of time (more than six months) of a researcher from a laboratory in one country of the European Community to a research centre in another country of the European Community;
- activities which enable communication and dissemination of information (especially where this is multidisiciplinary in nature) to be strengthened within the scientific and technical system of the European Economic Community.

Seven areas of activity have been selected for the experimental phase.

- Pharmacobiology is a multidisciplinary approach to the numerous scientific problems posed by the application of modern biology in this field particularly as regards inter and intra cellular communication;
- Solid State Physics: for example structure phenomena and the processes of preparing composite materials;
- Optics: particularly optoelectronics and the applied or theoretical development of the mathematics involved in this sector;
- Combustion: a theoretical approach involving new basic knowledge of systems experiencing imbalance and ignition phenomena (changes in material undergoing combustion);
- Photometry — Photoacoustics: particularly their application to the field of non destructive analysis;
- Interface phenomena: particularly catalysis and emulsification;
- Climatology: the study of transitory phenomena.

3. SUPPORT METHODS TO BE TESTED IN 1984

- Research Grants: payment of a grant to cover the travel, accomodation and research expenses, involved in the secondment of scientists to a laboratory in a country other than that in which they are currently employed upon research (within the EEC);
- Assistance intended to increase the mobility of researchers: a contribution to the dissemination of the best available knowledge and the development of contracts between researchers (subsidies);
- The twinning of laboratories in different countries: to enable researchers working in parallel in an advanced field of study in various countries of the Community to work together in order to achieve a "critical" scale: the allocation of a grant making it possible for researchers to meet, to carry out joint experiments and exchange results.

4. THE ALLOCATION OF COMMUNITY FINANCIAL SUPPORT

The Commission hopes to receive proposals corresponding to the specifications set out at points 2 and 3; these proposals should show the amount of support required. They will be evaluated by means of a system of referees set up under the aegis of the Committee for the European Development of Science and Technology (CODEST) which is responsible for advising the Commission on this matter.

The level of support given by the Commission will vary according to the method of intervention.

5. PROCEDURE

Any person or body (either in the public or private sector) wishing to learn more about the experimental stimulation action, or who wishes to submit a proposal should contact the following address as soon as possible:

General Directorate for Science Research and Development,
Division XII-A-2
Stimulation Action
Commission of the European Communities
200, Rue de La Loi
B — 1049 BRUSSELS
BELGIUM

Detailed information on this second call for proposals, and the forms upon which submissions should be made will be available upon request. Formal proposals which reach the Commission before 1 April 1984 will, if accepted, result in a contract for support during the same year. (W747)H

THIS LIST IS NEITHER EXCLUSIVE NOR EXHAUSTIVE,
AND ANY FIELD OF ACTIVITY OR ORIGINAL,
PROMISING DEVELOPMENT WHERE A TEST OF
STIMULATION SUPPORT METHODS CAN BE MADE,
MAY BE TAKEN INTO CONSIDERATION.

FELLOWSHIPS

Atlas Research Fellowship

St. Catherine's College, Oxford University

The Rutherford Appleton Laboratory of the Science and Engineering Research Council and St. Catherine's College invite applications from engineers, mathematicians or scientists for a joint Research Fellowship. The aim of this "Atlas Fellowship" is to encourage theoretical studies, particularly those involving computation, in an area of research supported by the Rutherford Appleton Laboratory and of interest to some Fellows of the College. These areas include the following broad fields: study of condensed matter by scattering of neutron beams; computer simulation of condensed phases, especially liquids; finite element methods applied to transport processes. Candidates will be asked to present the programme of research they would propose to follow.

The holder of the Fellowship will be expected to undertake independent research work and to spend the greater part of his/her time at the Rutherford Appleton Laboratory, where exceptionally powerful computer facilities are available. He/she will also be a Research Fellow of St. Catherine's College with the full rights and privileges of a Fellow and will be associated with a relevant University Department. The Rutherford Appleton Laboratory's involvement with many University research groups provides an excellent opportunity for contacts with other research workers engaged on a wide range of research programmes. The Fellowship provides an opportunity for some teaching experience, and for close personal contact with the College in other ways.

The Fellowship will be tenable for a period of three years and may be extended for a further two years for the completion of a total period of five years. The stipend will depend upon the age and experience of the candidate selected within the broad range £9,500 to £14,800.

For details of research fellows' rights at St. Catherine's College and application forms, write to Recruitment Office Personnel Group, Rutherford Appleton Laboratory, Chilton, Didcot, Oxon OX11 0QX, or telephone Abingdon 0235 445435 quoting reference No: VN 202.

The closing date for applications is 2nd March 1984

(1154)E

serc Rutherford Appleton Laboratory

THE ANIMAL HEALTH TRUST WOOLDRIDGE FARM LIVESTOCK FELLOWSHIP

Applications are invited from veterinarians and scientists with post-graduate research experience, who will design and undertake studies of major factors influencing the health and productivity of cattle, sheep or pigs.

The Fellowship is tenable for up to three years at an agreed place of work in the UK, commencing on 1st October, 1984.

The value of the Fellowship is in the region of £5,000/£8,500 plus a reasonable contribution towards essential expenses.

Further details and application forms are obtainable from the General Secretary, The Animal Health Trust, Lanwades Hall, Kennett, Newmarket, Suffolk CB8 7PN.

Closing date 31st March 1984. (1166)E

UNIVERSITE CATHOLIQUE DE LOUVAIN POST-DOCTORAL FELLOWSHIPS

— Spectroscopic study (E.P.R.-N.M.R.) of the molecular interactions at the solid-water interface: adsorption of ions by model colloids and cell walls. Preference given to a candidate experienced in physical chemistry of interfaces and/or magnetic spectroscopies.

— Multidisciplinary research dedicated to the implications of the physical chemistry of interfaces in biotechnology (cell and enzyme immobilization). Preference given to a candidate experienced in physical chemistry of interfaces, and/or microbiology, and/or biotechnology.

Positions available immediately; one year renewable. Salary of 39.000 B.Francs per month after tax deduction, or above depending on age, experience and family.

Applications accompanied by curriculum vitae, detailed information on the scientific background and the names of two references should be sent to

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF MICROBIOLOGY

POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited for this ARC-funded post, to work on the replication strategy of potexviruses and aspects of resistance. Experience in plant virology or nucleic acid biochemistry would be an advantage.

Post tenable for up to seventeen months from 1 May 1984.

Salary on the Research Fellow 1A scale £7,190 — £11,615 plus superannuation.

For further particulars phone 021-472 1301 ext 2559, quoting reference M2.

No formal application form. Three copies of application, including full Curriculum Vitae and naming three referees to Assistant Registrar, (Science and Engineering), PO Box 363 Birmingham B15 2TT by 24 February 1984. (1178)E

APPOINTMENTS WANTED

APPOINTMENTS WANTED

advertise your qualities and qualifications through the most influential science weekly in the world at a special reduced cost of *25p a word.* (Personal Box Numbers £1). Advertisements must be pre-paid and sent to: Nature Classified (Appts Wtd), 4 Little Essex Street, London WC2R 3LF. (890)B

STUDENTSHIPS

UNIVERSITY OF DUNDEE

DEPARTMENT OF BIOCHEMISTRY

RESEARCH STUDENTSHI
October 1984

Applications are invited for t above positions from graduates a undergraduates who hold or expe to obtain at least an upper seco class honour degree by this summe

The major research activities of t department are:-
(a) Membrane proteins: structur mobility and function
(b) Molecular mechanisms of enzyn regulation in mammalian cells hormones and drugs; genetic diseas associated with these enzymes.
(c) Use of recombinant DNA tec niques to study DNA structure a function; regulation of ge expression in procaryotes a eucaryotes.

Applications including a f curriculum vitae and names a addresses of three referees Professor P Cohen, Department Biochemistry, The Universit Dundee DD1 4HN, Scotland.

(1151)F

MRC REPRODUCTIVE BIOLOGY UNIT Edinburgh

RESEARCH STUDENTSHI

Applications are invited for t above PhD studentship tenable f three years from October 1984 work on the molecular basis human sperm function.

Applicants should have a goo honours degree or MSc in bi chemistry or a related subject.

Additional information can obtained from Dr R J Aitke Telephone 031-229 2575. App cations, together with the names two referees, should be sent to Administrative Officer, MR Reproductive Biology Unit, Cen for Reproductive Biology, Chalmers Street, Edinburgh EH 9EW, by February 29th 1984.

INTERNATIONAL SYMPOSIUM ON MONOCLONAL ANTIBODIES: BIOLOGICAL AND CLINICAL APPLICATIONS
Florence, Palazzo dei Congressi, October 16-19, 1984

Scientific Secretariat: A. Pinchera — G. Doria — F. Dammacco — A. Bargellesi
The meeting is intended to cover three broad areas of biological and clinical applications of monoclonal antibodies: Markers of the Immune System; Hormonal Receptors and Related Autoimmune Disorders; Experimental and Clinical Oncology.
The Scientific Program will consist of Invited Lecturers and Poster Sessions. A limited number of Posters will be selected for oral presentation.
Invited Speakers: L. Adorini (Italy), R. C. Bast (USA), C. A. Bona (USA), M. I. Colnaghi (Italy), P. Comoglio (Italy), G. Corte (Italy), S. Dower (USA), P. A. W. Edwards (UK), A. Falaschi (Italy), I. D. Goldfine (USA), M. F. Greaves (UK), G. L. Greene (USA), C. Grossi (Italy), S. Hakomori (USA), L. D. Kohn (USA), J. Lindstrom (USA), R. G. Lynch (USA), J. P. Mach (Switzerland), S. L. Morrison (USA), K. Rajewski (FRG), M. D. Scharff (USA), R. H. Schwartz (USA), J. Strominger (USA), J. Schlessinger (Israel), T. Tada (Japan), I. S. Trowbridge (USA), P. E. Thorpe (UK), J. C. Venter (USA), T. A. Waldmann (USA), L. N. Warner (USA).
The deadline for submission of Abstracts is June 15, 1984. For further information write to the *Organizing Secretariat:* Organizzazione Internazionale Congressi (O.I.C.), Via Gustavo Modena 19, 50121 Florence (Italy). Tel: (055) 53962-571082 — Telex 570243 OICCONGRE.

Preliminary Program — International Symposium on MONOCLONAL ANTIBODIES '84: BIOLOGICAL AND CLINICAL APPLICATIONS
Florence, October 16-19, 1984

Tuesday, October 16 — 17:00 — 19:00 OPENING CEREMONY
R. Masi (Italy): Presidential Address
A. Falaschi (Italy): New Frontiers of Biotechnology

Wednesday, October 17 MARKERS OF THE IMMUNE SYSTEM
Morning 8:30 — 12:20
Chairmen: G. DORIA and A. BARGELLESI
M. D. SCHARFF (USA): Advances in Monoclonal Antibody Technology
S. L. MORRISON (USA): Ig Gene Expression in Transformed Lymphoid Cells
C. A. BONA (USA): Regulatory Idiotopes
K. RAJEWSKI (FRG): Monoclonal Antibodies in the Analysis of the Idiotypic Network and the Selection of the Antibody Repertoire
J. STROMINGER (USA): Human Histocompability Antigens: Genes and Proteins
12:20 — 14:00 — LUNCH AND POSTERS
Afternoon 14:00 — 18:20
Chairmen: M. RICCI and F. DAMMACCO
L. ADORINI (Italy): Antigen-Specific Monoclonal T Cell Products
R. H. SCHWARTZ (USA): Cellular Co-Recognition of MHC and Antigen
T. TADA (Japan): The Immunoregulatory Molecules Studied with Monoclonal Antibodies
C. GROSSI (Italy): Multiple Marker Analysis of Human Lymphocyte Subpopulations
N. L. WARNER (USA): New Developments in the Definition of Human Leucocyte Subsets by Monoclonal Antibodies
M. F. GREAVES (UK): Human Lymphoid Malignancies
18:20-19:20
Chairmen: G. TRIDENTE and S. ROMAGNANI
POSTER DISCUSSION

Thursday, October 18 HORMONAL RECEPTORS AND RELATED AUTOIMMUNE DISORDERS
Morning 8:30 — 12:20 Chairmen: A. PINCHERA and A. ALBERTINI
L. D. KOHN (USA): Thyrotropin Receptor
I. D. GOLDFINE (USA): Insulin Receptor
J. LINDSTROM (USA): Acetylcholine Receptor
G. L. GREENE (USA): Immunochemical Studies of Estrogen Receptor in Normal and Neoplastic Tissues
B. MONCHARMONT (Italy): Application of Monoclonal Antibodies to the Study of the Estrogen Receptor Structure
12:20 — 14:00 — LUNCH AND POSTERS
Afternoon 14:00 — 17:00
Chairmen: M. SERIO and L. MARTINI
J. C. VENTER (USA): Monoclonal and Autoantibodies to Beta-Adrenergic Receptors
I. S. TROWBRIDGE (USA): The Biology of the Transferrin Receptor
J. SCHLESSINGER (Israel): Monoclonal Antibodies Against the Epidermal Growth Factor Receptor: A Versatile Tool for Structural and Mechanistic Studies.
T. A. WALDMANN (USA): Interleukin-2 Receptors on T Cells
17:00 — 18:00
Chairmen: M. MUGGEO and V. MACCHIA
POSTER DISCUSSION

Friday, October 19 EXPERIMENTAL AND CLINICAL ONCOLOGY
Morning — 8:30 — 12:20 Chairmen: G. SALVATORE and G. L. BURAGGI
P. COMOGLIO (Italy): Oncogene Products as Targets for Monoclonal Antibodies
S. HAKOMORI (USA): Glycolipid Tumor Cell Markers
R. G. LYNCH (USA): Myeloma Proteins as Targets and Inducers of Immunoregulatory Signals
M. I. COLNAGHI (Italy): Tumor Detection by Immunocytochemical and Radioimmunometric Methods
J. P. MACH (Switzerland): Detection of Tumors by Immunoscintigraphy Using Monoclonal Antibodies against Tumor Markers
12:20 — 14:00 — LUNCH AND POSTERS
Afternoon 14:00 — 17:40 Chairmen: U. MELDOLESI and G. DELLA PORTA
P. A. W. EDWARDS (UK): Human Monoclonal Antibodies and the Prospects for Therapy
R. C. BAST (USA): Treatment of Bone Marrow with Monoclonal Antibodies *in Vitro*
G. CORTE (Italy: Monoclonal Antibodies for the Control of GVH Reaction after Bone Marrow Transplantation
S. DOWER (USA): A Rational Approach to the Development of Monoclonal Antibody Reagents for *in Vivo* Tumor Diagnosis and Treatment
P. E. THORPE (UK): Monoclonal Antibody-Toxin Conjugates
17:40 — 18:40 Chairmen: A. NICOLIN and L. FRATI

GLAXO GROUP RESEARCH LIMITED
BASIC SCIENCE IN GASTROENTEROLOGY SYMPOSIA
Seventh Symposium of the Series

GASTROINTESTINAL CARCINOGENESIS

London — 24 April 1984

Organisers: J. M. Polak, S. R. Bloom, N. A. Wright, A. G. Butler

Invited speakers include

D. Britton, UK
W.W.L. Chang, USA
P. Correa, USA
M. Hill, UK
J. Jass, UK
M. Lipkin, USA
B. Morson, UK
R.R. Peto, UK
C.D. Potten, UK
R. Riddell, USA
J.P. Sunter, UK
J. Weisburger, USA
R.C.N. Williamson, UK

Topics include
Epidemiology, Chemical Carcinogenesis, Cell Proliferation, Environmental Factors, Dysplasia, Pre-cancerous Lesions, Atrophic Gastritis

Registration and Lunch — £10.00

For further details and Application Form please contact:
A.G. Butler, Medical Division, Glaxo Group Research Ltd., Ware, Herts. SG12 0DJ. Telephone No. 0920 3993.

Closing date for applications: 13 April 1984.

(951)M

FIFTH INTERNATIONAL OCEAN DISPOSAL SYMPOSIUM
At Oregon State University
Corvallis, Oregon, USA

Topics include:

* Biological and toxicological effects of wastes in the ocean;
* Biological accumulation and concentration of wastes;
* Dispersion, settling, and transport processes;
* Eutrophication in coastal ecosystems;
* Physical and biochemical modelling on the effects of wastes in the ocean;
* Physical, chemical, and biological interactions of wastes.

Send Abstract (200-300 words), by 1 May 1984, to: Prof. Iver W. Duedall, Executive Committee, Fifth International Ocean Disposal Symposium, Department of Oceanography and Ocean Engineering, Florida Institute of Technology, Melbourne, FL 32901 USA. Telephone: 305 723-3701.

(NW280)M

LEUKAEMIA RESEARCH FUND
International Research Symposium on **DIAGNOSIS AND CLASSIFICATION OF LEUKAEMIA** will be held at the Royal College of Physicians, London on Thursday 5th April 1984. Registration fee (including lunch) £12. For programme details and registration form apply to: **Leukaemia Research Fund, 43 Great Ormond Street, London WC1N 3JJ. (Tel: 01-405 0101)**

FOR SALE and WANTED

ADDA-Interface for Apple. Use your Apple II for data acquisition, storage and signal averaging. Converts your analog oscilloscope or monitor to a digital storage oscilloscope with storage on discs. Dual trace option and other features. Package contains a plug-in card, friendly program on disc and manual. Requires any Apple II with language card (64K) and 2 disc drives. Price $725. 10 day trial. For information: OSI, 430 S 46th St Phila. PA 19143. (NW270)L

CONFERENCES and COURSES

Royal Postgraduate Medical School
(University of London)

TOXICITY TESTING — THE HUMAN DIMENSION

A Workshop on the Toxicity Testing of Drugs and Chemicals
April 2-6 1984
Department of Clinical Pharmacology
Royal Postgraduate Medical School, London

The Workshop will consist of a series of invited lectures and discussion sessions and will cover the following topics: current procedures — are they adequate; new developments in toxicity testing; in-depth discussions of carcinogenicity, teratotoxicity and immunotoxicity; reviews of recent problems in drug toxicity including benoxaprofen and perhexiline; the detection of drug toxicity in man.

Speakers will include: Dr. H. Amos, Professor R. Batchelor, Professor F. Beck, Professor A. M. Breckenridge, Dr. R. Brimblecombe, Dr. D. M. Davis, Professor G. Dworking, Professor Sir Abraham Goldberg, Professor D. G. Grahame-Smith, Professor D. F. Hawkins, Dr. R. Hess, Dr. W. Inman, Dr. G. Jones, Dr. Barbara MacGibbon, Dr. D. W. Nebert, Dr. R. Peto, Professor D. E. Poswillo, Dr. I. F. H. Purchase, Dr. F. Sullivan, Professor P. Turner, Professor K. Weinbren.

For further information and registration forms contact: School Office (SSC), Royal Postgraduate Medical School, Hammersmith Hospital, Ducane Road, London W12 0HS. (Tel: 01-743 2030 ext 351).

Course Organisers: Dr. A. R. Boobis, Professor D. S. Davies and Professor C. T. Dollery.

WE APOLOGISE TO THOSE WHO MAY HAVE EXPERIENCED SOME DELAY IN RECEIVING FURTHER PARTICULARS OF THE COURSE. THIS WAS DUE TO A POSTAL STRIKE IN OUR LOCAL SORTING OFFICE DURING DECEMBER. YOUR ENQUIRIES HAVE NOW BEEN RECEIVED AND ARE BEING DEALT WITH.

Closing date for applications 24 February 1984. (1170)C

BIOCHEMICAL SOCIETY
HARDEN CONFERENCES

22nd: "PLANT GENES: STRUCTURE, EXPRESSION, MOBILITY"
Wye College, Ashford, Kent, 9—14 September 1984
Chairman and Organizer: C.J. Leaver (Edinburgh
Principal Topics: Nuclear Gene Structure and Organization; Organization and Information Content of Plastid and Mitochondrial Genomes; Developmental, Environmental and Hormonal Regulation of Gene Expression; Gene Mobility; Expression of Plant Genes in Micro-organisms; Plant Genes and Plant Breeding.
Conference fee and full board **£160** including VAT.

23rd: "MOLECULAR AND CELLULAR ASPECTS OF REPRODUCTION"
Wye College, Ashford, Kent, 16—21 September 1984
Chairman and Organizer: R.B. Heap (Babraham)
Principal Topics: Regulation of Gametogenesis; Developmental Control; Genome Manipulation; Sex Determination; Molecular Action of Hormones; Cellular Control of Hormone Secretion.
Conference and full board **£160** including VAT.

Information: Meetings Officer, Biochemical Society, 7 Warwick Court, High Holborn, London WC1R 5DP, U.K.

nature is keeping ahead. Are you being left behind?

New research results, the very latest international science news, key papers by the world's leading scientists and speed of publication ensure *Nature* remains one of the foremost weekly scientific journals in the world.

But if you're tied in to a circulation list at work, all this vital weekly information will undoubtedly reach you late, often incomplete and sometimes not at all.

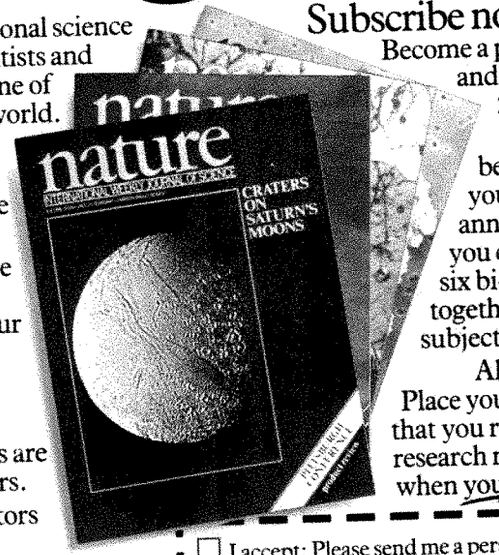
With your own personal copy, you solve the problem. Every week you'll have all the latest research results and science news in your hands within days of publication:

News reports from throughout the world of science and technology.

News and Views section, where new ideas are analysed and discussed by leading researchers.

Articles and Letters in which key investigators disclose their work for the first time.

Book Reviews – Eminent figures offer expert judgments on a wide variety of recent publications.



Special Issues providing an in-depth treatment of topics of importance.

Product Reviews – Detailed descriptions of laboratory equipment newly available.

Classified Advertisements for a wide variety of positions all over the world.

You will no longer be dependent upon other people passing down the 'list' copy, and because you will automatically receive every issue, you won't risk missing a single copy through absence from work. Moreover, you keep all this key information for permanent reference.

Through your door every week

Subscribe now – at Half Price

Become a personal subscriber now and you will receive a discount of 50% off the full rate.

All 51 weekly issues will be delivered to the address of your choice. You can start your annual subscription with any issue you choose. And you will receive six bi-monthly author indexes, together with the annual index of subject and author.

All this for just 94p a week.

Place your order now and make certain that you receive the scientific news and research results crucial to your work when you want them.

☐ I accept: Please send me a personal subscription to *Nature* for one year (51 issues) at the special half-price rate of £49.00.

☐ I enclose my personal cheque for £49.00 made payable to *Nature*. (Note: Institutional cheques cannot be accepted at this special rate).

☐ Please charge to my credit card account.

NATURE'S BIOREACTOR

The New Bio-Response MCT* (Mass Culturing Technique) System Delivers Monoclonal Antibodies And Other Mammalian Cell Products When You Need Them—From Grams To Kilograms.

Insufficient quantities of desired peptides are a key cause of expensive research and production delays. The MCT system is a *new* and *unique* mammalian cell culturing process designed to overcome the obstacle of insufficient quantities of peptides by delivering the quantity you need...*when you need it!* Additionally, every step in MCT production has been developed to contain costs now and in the future while maintaining exceptional purity and quality in mammalian cell proteins.

Quantity

Unlike conventional cell-culture methods, the MCT system uses "fresh," free-flowing lymph directly from a cow. Following treatment, the lymph is continuously diffused into and out of a growth chamber. This nearly *in vivo* growth environment stimulates continuous and optimal protein secretion. The result? Large quantities of desired proteins enabling you to move to the clinic or market...*faster.*

Cost

Unlike conventional cell-culture methods that require extensive labor forces and expensive growth mediums, Bio-Response's MCT is a closed, steady-state system. In essence, the MCT system starts with a low-cost lifeline—a feeding cow—and ends with a pure, quality product. MCT ...*an optimal system at low cost.*

Purity

Unlike conventional cell-culture methods, the MCT system is designed to insure purity without tedious processing. By directing the lymph across semi-permeable membranes, MCT provides both separation of media protein from desired cell products, and a continuous nutrient flow. The ability to add or withdraw from the chamber to maintain optimal cell density permits continuous harvest of a highly pure product.

Quality

Unlike conventional methods of production that attempt to create biologically active mammalian cell products, the MCT system provides a pure-mammalian product—an exact copy of the original protein and, in the case of non-antibody polypeptides, uncompromised by inappropriate glycosylation and disulfide bond formation. There is a growing consensus favoring products produced in a mammalian cell-culture system, such as the Bio-Response MCT system.

The FRAC-100 Fraction Collector

The FRAC-100 does what any other small fraction collector does – collects fractions, PLUS...

The FRAC-100 *will fulfil all your needs for basic fractionation requirements. As a conventional collector the FRAC-100 is unequaled in performance and reliability. Simplicity in design (3 moving parts) and control (flexible fractionation parameters accessed by a multifunction key board) accomplish fractionation routines previously attainable only with large, expensive instruments.*

The FRAC-100, *as a sophisticated fraction collector presents unique data handling and integration capabilities. The input of a 0–10 mV detector signal is processed by the FRAC-100 to report as a digital display such separation parameters as peak height, peak width, peak retention and peak area. The addition of a PSV-100 solenoid valve enables selective fractionation of only the peak material as judged by a slope detector defined by a programmable threshold value.*

The FRAC-100 – as a small, simple inexpensive fraction collector – your best choice, – as a small sophisticated inexpensive collector, far beyond anything presently available – your only choice.

British Journal of Pharmacology

Published monthly on behalf of the British Pharmacological Society, the British Journal of Pharmacology contains original papers submitted from all parts of the world making it one of the most respected journals for all those professionally involved in the pharmacological sciences. It contains up-to-date papers of the highest quality on all aspects of drug action and is thus a vital source of information for physiologists, clinicians, immunologists, molecular biologists and biochemists as well as pharmacologists.

Subscription Prices
UK £145.00, USA/Canada US $360.00 surface, US $440 airmail,
Rest of World £160.00 surface, £210.00 airmail.

HUMAN TOXICOLOGY
An International Journal

Published bi-monthly this new journal features the following material:

* original papers of a high scientific standard on all aspects of human toxicology, embracing both animal research and studies with humans
* short communications
* invited comment on current matters of professional interest
* editorials on topical issues
* review papers
* book reviews

Subscription Prices
UK £65.00,
USA Canada
US $150.00 surface,
US $185.00 airmail,
Rest of World
£75.00 surface,
£95.00 airmail.

Pharmaceutical Medicine

New For 1984...

A new, independent, quarterly journal for the critical assessment of new and old methods employed to test drugs in man. To promote the discipline of pharmaceutical medicine and cover those activities germane to human testing of drugs, papers will appear on human pharmacology, clinical investigation, comparative clinical trials, and epidemiological studies. The latter will inevitably be associated with drug safety and post-marketing surveillance. The problems of quality control and analysis of laboratory tests will be addressed, and the handling of clinical trial data. The design and statistical analysis of clinical studies will also feature.

Pharmaceutical Medicine will provide invited contributions, reviews, news and opinion. A major feature will be abstracts of papers published elsewhere giving new means of assessing drugs.

The Journal will not take an overtly political or commercial position, but any matters affecting ways and means of assessing drug efficacy and safety, including governmental regulations, will be discussed.

Subscription Rates
UK and Eire: £45.00, USA Canada: Surface US $95.00, Rest of World: Surface £63.00

British Journal of Anaesthesia

The British Journal of Anaesthesia has consistently been the leading independent journal in anaesthesia enjoying international contributions and readership.

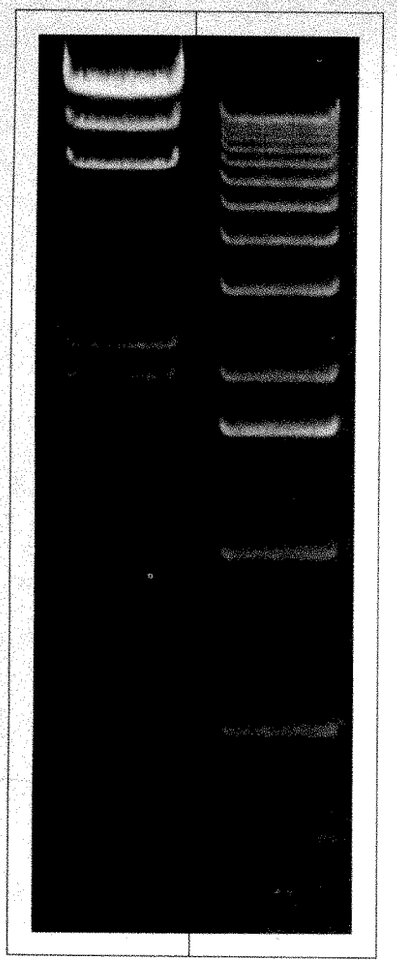
Published monthly the journal offers:

* Sections on laboratory investigation, clinical research, case reports and information on apparatus.
* A correspondence section in which views are exchanged through short communications and comments on matters of professional interest.
* Book Reviews.
* Postgraduate Educational Issues, on both clinical and basic themes, produced twice a year – indispensable to established clinician and trainee alike.

Subscription Prices UK £38.50, USA/Canada US $90.00,
Rest of World £53.00 surface, £95.00 airmail,
Trainee rates UK £24.00, US $50.00.

The British Journal of Cancer

Published monthly on behalf of the Cancer Research Campaign, The British Journal of Cancer is one of the leading cancer journals in the world, publishing articles in all the major scientific disciplines relevant to the subject. The journal provides papers and short communications submitted by scientists from countries throughout the world. In addition, the Proceedings of the meetings of the British Association for Cancer Research are regularly published in the journal. From time to time other selected national and international meetings are also covered. Up-to-date book reviews appear in each issue.



Subscription Prices
UK £99.00, USA/Canada US $240.00 surface,
US $285.00 airmail,
Rest of World £124.00 surface,
£160.00 airmail.

λ-*Hind* III 1 Kb Ladder

φX *Hae*III 123 bp Ladder

(Tracking dye) Oligo (dT) Ladder

Do your DNA markers measure up to the BRL "LADDERS"?

Do your markers provide enough reference points for accurate DNA sizing? Are the fragments spaced for confident calibration, or are there gaps that leave you guessing? BRL's exclusive Ladders measure up on both counts: these new markers contain *more fragments* than ordinary DNA standards, and the fragments are more evenly distributed. For calibration of DNAs over a wide range of sizes, BRL Ladders are the most accurate and convenient markers available.

For mapping and cloning applications, choose the 1 Kilobase (1 Kb) Ladder or the 123 Base Pair (123 bp) Ladder. The 1 Kb Ladder is composed of 12 fragments, ranging in size from 1,018 bp to 12,216 bp, in increments of 1,018 bp, and four additional fragments that act as reference markers. The 123 Base Pair Ladder consists of 34 multiples of a 123 bp fragment, covering the range from 123 bp to 4,182 bp. The smallest bands of both the 1 Kb Ladder and the 123 bp Ladder can be detected easily without overloading the gel, because smaller fragments are present in greater concentration than larger ones.

The Oligo $(dT)_{4\text{-}22}$ Ladder is the first marker available for nucleic acid sequencing and oligonucleotide synthesis. Consisting of 19 fragments, each increasing by 1 base from 4 to 22 bases, the Oligo $(dT)_{4;22}$ Ladder provides an accurate reference for determining the location and size of the smallest fragments on the gel.

NATURE VOL. 307 16 FEBRUARY 1984

COVER

SHEEP-GOAT CHIMAERAS

A sheep-goat chimaera produced by combining one 8-cell sheep embryo with three 8-cell goat embryos. It is about 1-year-old and exhibits various characters confirming its chimaeric nature — a mixture of hairy and woolly areas in its coat, goat-like horns twisted like sheep horns and blood containing sheep and goat red blood cells. This animal and others are described on p.634 and p.637.

NATURE CLASSIFIED

Professional appointments — Research posts — Studentships — Fellowships — Conferences — Courses — Seminars — Symposia: Back pages

Next week in *Nature*:

- What use are lie detectors?
- Rotation of Saturn's moon Hyperion
- New mine determination of Newton's gravitational constant
- New chemical oscillator
- Visualizing real and apparent movement
- Oestrogen receptors localized in target cell nucleus
- Evolutionary origin of eubacteria
- Calcium-activated potassium channels in secretion
- Simian virus genetic elements induce altered chromatin structures
- R.V. Jones reviews a new biography of Ernest Rutherford

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

Announcing a new Elsevier journal...

Computers and Electronics in Agriculture

Editor-in-Chief: Professor Jerry Lambert
Dept of Agricultural Engineering
Clemson University
CLEMSON, S.C. 29631, U.S.A.

Aims: The aim of the journal is to provide an international forum for papers and notes on the application of computers and electronics to agriculture. Hardware and software aspects of computers are included. Electronics coverage includes instrumentation, data acquisition and control of any facet of agriculture. The term agriculture is interpreted broadly to include horticulture, forestry, veterinary medicine, crop and livestock production.

Subscription Information
1985: Volume 1 in 4 issues
Price: US$ 69.25 / Dfl. 180.00 excluding postage
Volume 1/1 is scheduled for late 1984

Submission of Articles
Manuscripts should be submitted, in triplicate, to the Editorial Secretariat, "Computers and Electronics in Agriculture", P.O. Box 330, 1000 AH Amsterdam, The Netherlands. Contributors from North America can submit papers directly to Professor Jerry Lambert.

COMPUTERS AND ELECTRONICS IN AGRICULTURE HAS NO PAGE CHARGES

No end to nuclear decay?

The stagnation of the nuclear power industry in the United States should be an incentive for radical thinking rather than an excuse for despair.

THE predicament of the nuclear power industry in the United States will get worse before it gets better. Last July, nuclear power provided the occasion for the biggest municipal default in history, when the Washington Public Power Supply System failed to meet its payments on bonds worth more than $2,000 million. More financial embarrassments are in store. It appears to be only a matter of time, for example, before the Long Island Lighting Company (LILCO) concedes that its Shoreham plant, which is already a decade behind schedule and seems likely to cost 15 times more than intended, will never be allowed to operate. LILCO's chief executive, Dr William Catacosinos, admitted for the first time last week that it might be simpler for the utility to abandon Shoreham than to continue its enervating struggle with the local municipality, Suffolk County. Suffolk, it will be remembered, has done its utmost to thwart LILCO's plans for Long Island by refusing to participate in the emergency evacuation planning mandated by the Nuclear Regulatory Commission (NRC).

Shoreham's plight is a depressingly familiar (but exceptionally acute) compound of engineering, economic and political failures, failures that have contributed to the fact that there has not been a single new order for a nuclear reactor in the United States since 1978. The nuclear industry, supported by the Reagan Administration, lays much of the blame at the door of NRC. Less cumbersome procedures, fewer opportunities for public intervention and a limit on the number of design "backfits" ordered by NRC could, it is suggested, transform the economics of reactor construction. But there is little point in looking for relief in that direction. Congress, backed by public opinion (half of the public is opposed to building nuclear plants, a third supports it), is in no mood to reduce the powers of NRC, a body which is criticized for too cosy a relationship with the industry at least as often as it is accused of over-zealous enforcement of its rules. There may indeed be a case for strengthening NRC procedures in order to revive public confidence in the safety of nuclear energy.

It is in any case far from clear that regulatory reform by itself would do much to alter the predicament of the industry. The two main causes of that predicament are the abrupt fall in the rate of growth in electricity demand since 1973 and the simultaneous increase in the costs of nuclear reactor construction. Between 1960 and 1972, electric utilities took for granted annual growth rates of 7 per cent, and it is on those assumptions that existing nuclear power construction was predicted. In practice, growth has averaged only 2.5 per cent a year since 1973. Moreover, the costs of building nuclear plants doubled in constant dollars during the 1970s and are expected to increase by another 80 per cent for plants now under construction. Some of this increase can be ascribed to new regulatory requirements but not much, according to a new study, *Nuclear Power in an Age of Uncertainty*, published by the Office of Technology Assessment (OTA) last week. OTA points out that of the group of plants now being built, the most expensive is expected to cost more than four times as much as the least expensive. The variation has something to do with regional labour costs and differences in weather but is primarily a result of differences in the competence and experience of management.

So it is to its own management, rather than to external agencies, that the nuclear industry should look for a way out of the impasse in which it finds itself. Unfortunately, industry managers show little enthusiasm for tackling any of the major structural problems that have to be solved. There is a temptation instead to ride out the hiatus in orders for new plants in the hope that demand for nuclear power will revive when the demand for electricity revives. Meanwhile there is a reasonable living to be made by servicing existing plants and, from time to time, selling reactors overseas.

That strategy might work, if the hoped-for recovery were to come within five years. But if the hiatus lasts a decade or more, the prospects for reviving the industry are much less promising. According to OTA, the lack of orders for new plants is already creating shortages of spare parts and personnel. Enrolment for nuclear engineering degrees has declined since the mid-1970s, and graduate numbers will barely be enough to fill the anticipated need for 6,000 engineers to operate plants by 1991. Instead of alternately sitting on its hands and wringing them, the industry should be acting now to ensure that the hiatus ends sooner rather than later.

What can be done? For a start, the industry could stop talking about standardized designs and actually begin to standardize them. Without some degree of standardization, as in France, construction of nuclear reactors is unlikely to be able to compete with coal-fired plants. Standardization would require ruthless surgery to reduce the proliferation of vendors and designers, but that would be better than seeing the whole industry gradually collapse under the weight of its own diversity. Second, the industry could begin to address some of the concerns of its critics, by taking more visible measures to ensure competent management and to enhance safety standards. Why not look seriously at alternatives to the much-criticized light-water reactors — at high-temperature gas-cooled reactors or the Swedish PIUS (process inherent ultimately safe) reactors, in which the core and other critical reactor components are submerged in a pool of water? □

How to help Orlov

Some of the schemes being considered in the West on behalf of Yuri Orlov will not work.

SEVEN years ago, the Soviet accelerator physicist, Yuri Orlov, was arrested in Moscow and charged with making anti-Soviet propaganda. At his trial, Orlov was sentenced to seven years in gaol followed by five years of exile. During the first part of his spell in prison, Orlov seems to have been a thorn in the flesh of the prison authorities, protesting at censorship of mail and the molestation of prisoners by their guards. During this period, he seems also to have kept his hand in with his physics. More recently Orlov seems to have been ill, perhaps gravely so. Orlov's case, like Sakharov's, has become to many in the West a test of Soviet attitudes towards professional people who happen to disagree with government policy. Excitement has come to a head (see page 585) now that the more rigorous part of Orlov's sentence is at an end. Will he be released into exile, perhaps abroad, or cynically be kept in gaol?

Orlov was the chief organizer of the group active in Moscow in the mid-1970s in the monitoring within the Soviet Union of the Helsinki agreements. This formless group of undertakings commits its signatories, among other things, to permit the free

0028-0836/84/070581-01$01.00

© 1984 Macmillan Journals Ltd

flow of ideas and even people between themselves. Orlov and company have plenty to complain about.

There have been several well-publicized international shouting matches, most recently at Madrid, but the agreements have also led to the Stockholm talks on European security, now under way, which may yet make ten years of diplomacy seem worthwhile. In any case, Orlov was not imprisoned for having discovered that the Helsinki agreements were being illiberally interpreted (more simply, ignored) by Soviet authorities, but for having said so, and for having distributed his complaints abroad.

By that test, Orlov is unquestionably a criminal. Did not a Soviet court, whose judicial independence is guaranteed by the Soviet constitution, come to that conclusion? Is it not, in any case, well known that the Soviet authorities, like their tsarist predecessors, have always taken a serious view of what seems to be disloyalty? With the obligations of individuals to the state counting for more than the state's obligation towards its people as individuals, Orlov must have known that he was asking for trouble. Orlov's activities had much in common with those of earlier trouble-makers. Medvedev, Solzhenitsyn and the like find some weakness in the system, such as the constitutional right that private correspondence should not be interfered with, exploit it to the full and, provided they keep within the law, sooner or later find themselves at an airport with an exit visa in their pocket. Orlov must have overstepped the line.

This is how Orlov's case seems to many honest Soviet citizens. People elsewhere distressed at Orlov's plight must take that disconcerting circumstance into their calculations. Two conclusions follow. First, on compassionate grounds, anything that will help to release Orlov from the plight in which he finds himself is to be welcomed. If the petition signed by 2,600 French physicists, or the proposal being canvassed among the accelerator people at Geneva that Orlov should be offered a job at the European Organization for Nuclear Research (CERN), will help towards that end, all well and good. But the chances are not high. That is why this sad occasion should be a reminder to complainants in the West that their quarrel with the Soviet authorities goes deeper than the circumstances of Orlov's imprisonment and is tantamount to a protest against Soviet law and the manner in which it is interpreted. But sovereign governments do not often change their legislation at the behest of people who live elsewhere. So, for the long haul, the complainants must find subtle ways of making their opinions felt. The proposal, put forward last week, that there should be an Orlov Prize to honour people like him, will not help and may even hinder. Breaking off such personal scientific collaborations with Soviet scientists as have survived the past few years would be similarly nugatory. It will be better to keep the links going and to use them as a means of convincing collaborators that there are good reasons why the law needs changing. Orlov's objective, after all, is that his own brave act should ensure that there is less need of an army of successors. □

What hope for Esprit?

The European plan for information technology research is likely to be launched too late.

THE European Communities are more conspicuously than usual travelling in cloud-cuckoo land. Last week, the Commission, the Communities' executive authority, put the finishing touches to its plan for supporting long-term research in information technology by means of an intricate system of research contracts to be let by Brussels to companies and other research organizations which are themselves willing to meet half the cost.

The European strategic programme of research and development in information technology (known as Esprit) has recently been nurtured by Etienne Davignon, the Commissioner for Industry in Brussels, who has been shuttling about Europe seeking promises of support. On Monday, Davignon spent 50 minutes at 10 Downing Street with the British Prime Minister; the hope now is that if British objections can be overcome, the project will be approved at a meeting of ministers on 28 February, whereupon the Commission will be free to spend roughly US$400 million sterling of its own money provided that its partners commit an equal sum over the succeeding five years. The drawback, for the time being set aside in Brussels, is that the Commission is certain on present form to run out of funds between June and September. In short, the Commission has no money for projects like Esprit, and will not know whether it will be in funds again until the meeting of the heads of European governments fixed for 20 and 21 March. On recent form, the chances that the Communities' deep-seated differences can be resolved at a single meeting, and before the last minute has arrived (which will not be until June), are negligible.

So will Esprit be another European dream impaled on the failure of European governments to agree what should be done with their common enterprise? If it is, it will not be the first casualty of this kind. In the 1950s, Euratom, then legally a community in its own right, embarked on an ambitious programme for the development of nuclear reactors whose hallmark was that their design had nothing in common with those of the reactors being developed in member states. Member governments would not countenance the threat of competition between their own national nuclear energy establishments and the common enterprise, but the result was what everybody would have been entitled to predict: Euratom's projects failed (as did many of those mounted nationally). The idea that there might be a European project to strengthen the technology of the computer and communications industry was the most prominent of the proposals canvassed in the late 1960s by M. Pierre Aigrain, then President Pompidou's chief scientist. That came to grief for two reasons — the resistance of European telecommunications monopolies to the suggestion that their own research was insufficient and the lack of a plan to suggest how a common research programme supported by established companies or nationalized industries could nevertheless yield benefits that would be widely shared. Aigrain's project came too soon.

The Commission's latest attempt to breathe life into European information technology has obviously been designed to avoid these pitfalls, but has weaknesses of its own. Participation in the programme will be voluntary, but collaborating companies or consortia will have to commit resources to projects that the Commission supports. This will ensure a degree of seriousness. There are also rules about the availability of the results of research and development projects although, inevitably and even equitably, the partners in the research projects will have an advantage over others in their exploitation deriving from familiarity with the work. Perhaps the most encouraging feature of the Esprit programme is that it seems already to have fostered a degree of collaboration between European companies hitherto not much used to talking to each other. But the question remains of whether Esprit is what Europe most needs.

That information technology offers great opportunities for European industry, and that technology of the kind now being applied is likely to seem, a few decades from now, a rudimentary tool, are nowhere denied. Most industrial organizations recognize which way the wind is blowing. But the impediments to faster development consist not so much of the lack of development projects as of the shortage of people able to turn bright ideas into working machines decisively and quickly, the lack of technical people able to service the machines actually sold to customers (which demands more skill than that required to order a package of software from a list) and too little support for really long-term projects, those that might lead to optical computers for example (see *Nature* 9 February, p.494). For all the delicacy with which Esprit has been conceived, the programme will help towards these ends only incidentally, by training people. Might not the same result have been obtained by other means? (The same criticism can be made of the British Government's Alvey programme.) The risk in what the Commission is proposing is that a great deal of money (which does not exist) may be spent ineffectually. The danger is that if the Commission fails with this huge project, it may not be given another chance. □

European community

French visions of Europe and space

At last, a French phoenix has arisen from the ashes of the European summit at Athens last December. In Athens, President François Mitterrand of France apparently put paid to all hopes of negotiation with Britain over the future of the European Community. In The Hague last week, he explained his action: not directly, but by presenting a technological vision of a new Europe, in which the old conflicts would be something of a past age.

One element of this future would be a European space station, as a military observation post in the first place, but one that could also carry laser and other star wars weaponry for the defence of Europe.

Meanwhile, M. Mitterrand proposed only partial solutions to Europe's overriding political problem (the European budget), solutions which are unlikely to find favour with the crusading British Prime Minister, Mrs Margaret Thatcher.

Surprisingly, one of M. Mitterrand's most favoured ministers, M. Laurent Fabius (industry and research) seemed last week to have been caught a little un-

prepared by his president's commitment to a space station. Speaking at a meeting of European Parliament socialists in Toulouse, in south-west France, Fabius described the station as having commercial, scientific and strategic purposes — with, it was implied, the "strategic" element firmly relegated to third place. The French space agency CNES had been studying the possibility of such a station for a few months, said an aide to M. Fabius, although the CNES director-general had earlier denied its.

Certainly, President Mitterrand has been taking an increasingly independent approach to European policy lately, so much so that French officials have occasionally been seen to be announcing conflicting policies. This apparent chaos, however, is probably the consequence of Mitterrand's commitment to a vision which becomes more dazzling — and perhaps more blinding — the worse becomes France's international and internal position. (Internally, Mitterrand is facing rioting in factories against his restructuring policies, and a probable rout at the European Parliament polls in the summer.)

Putting it boldly, the Mitterrand vision is this: the European Community is out of date — and so are Europe's defence arrangements with the United States. So why not try for something completely new?

The European Community, for example, is based on post-war treaties which saw iron, steel, coal and nuclear as the key economic technologies. Now the key technologies are electronics, informatics, aerospace and biotechnology. The Community must be based on these, says M. Mitterrand, echoed by Fabius at Toulouse.

Equally, M. Mitterrand is disturbed by President Reagan's attitude to Europe, both technological and military, and — with France outside the North Atlantic Treaty Organization — he feels freer than most in Europe to propose something approaching an independent nuclear defence: hence the European space station.

Here, however, M. Mitterrand mixes military and industrial motives. While CNES has not admitted to a military space station study, it has since 1981 been studying a non-military one (dubbed Solaris), along with a recoverable low-orbit injector (Hermes) looking much like the space shuttle. Clearly, the object was to give Europe the possibility of recovery, repair, refuelling, construction and other options in space that the shuttle gives the United States but that Ariane has not given Europe (Ariane 5 — already on the drawing board — could launch a future Hermes).

In M. Mitterrand's mind at The Hague, these essentially commercial questions of Europe's industrial place in space in the 1990s were being mixed with other issues, but his overall dream was clearly of a brave new European Community based on brave new ideas.

Unfortunately, neither Mitterrand nor Fabius last week had much to say about mundane things such as the price of milk and the beef mountain, which may cause the French vision to become a mirage.

Robert Walgate

UN biotechnology

Let a hundred labs bloom

New Delhi

The contentious issue of the location of the International Centre for Genetic Engineering and Biotechnology for developing countries, sponsored by the United Nations Industrial Development Organization (UNIDO), seems to have been resolved. Although the original intention was to set up the institute in a developing country, the preparatory committee for the centre has now recommended that it is split into two components to be established in New Delhi, India, and Trieste, Italy.

The committee, meeting in Vienna at the end of January, suggested that the New Delhi component should concentrate on research in agriculture and human and animal health and that the Trieste laboratory should emphasize industrial microbiology and energy research. The offers from the two countries have been found to be most attractive.

A high-level meeting of the national representatives on 3 April will in all probability approve this decision, reached by the preparatory committee of 27 member countries. The committee was set up after the abortive Madrid meeting in September last year failed to decide on a location, following which more than one centre seemed a necessary compromise.

The decision reflects a major victory for India in the teeth of opposition from the UNIDO scientific committee which had favoured siting the centre in Belgium, Thailand or Italy. The committee said that these countries had sufficient merits to offer good prospects for the foundation of the international centre. India, like Cuba and Pakistan, had been ruled out on the grounds that its background in basic science is insufficient and that it would be difficult to attract good scientists.

This argument has now been rejected. What ultimately clinched the issue in favour of India was the specific outline of the offer involving some US $19 million. The offer includes land, buildings and laboratories; technical and auxiliary staff; permanent equipment and $5 million to cover recurring costs for running the centre for five years.

The government has promised that the New Delhi centre will have "high standards of scientific and laboratory facilities dedicated to solving problems relevant to developing countries in a highly focused and multidisciplinary approach". It will also provide training to scientific and technical personnel from developing countries.

The preparatory committee also tries not to displease the other nations that had also staked their claim to host the international centre. They can set up their own units affiliated with the New Delhi and Trieste centres and funds for them will also be provided through international sources. These affiliated units can be converted into centres by the board of governors of the new centre following a review after three years of operation by the New Delhi and Trieste Laboratories.

Recombinant DNA

Watch on human experiments

Washington

THE Recombinant DNA Advisory Committee (RAC) in the United States last week reaffirmed its intention to review any experiments involving human subjects or the release of recombinant organisms into the environment. Under rule changes adopted overwhelmingly by the committee, any proposal to transfer recombinant DNA into human subjects would have to be cleared by the full RAC.

Although the rules are legally binding only upon recipients of federal research money, industry and all government agencies have agreed voluntarily to follow the RAC procedures.

RAC's decision formally to require a review of human genetic engineering experiments was prompted largely by the demise last year of the President's Commission on Bioethics and the resulting concern that no group was monitoring developments in this field. RAC also decided to establish a nine-member working group, made up of scientists, lawyers and ethicists, to look at any human genetic engineering proposals. This move parallels a legislative proposal by Representative Albert Gore (Democrat, Tennessee) that would create a human genetic engineering commission with similarly broad representation. That proposal passed the House last year, but was never enacted into law. RAC itself is dominated by scientists and physicians.

In a related discussion of the scope of RAC's oversight, RAC appeared committed to continuing to review deliberate environmental release experiments and industrial activities. The Food and Drug Administration and the Department of Agriculture offered strong support for RAC's role in these areas; the Environmental Protection Agency (EPA), which has announced its intention eventually to regulate deliberate release of recombinant organisms under the Toxic Substances Control Act, said at last week's RAC meeting that it supported RAC's handling these areas at least until EPA's regulations are issued. A report released last week by the staff of Representative Gore's subcommittee questioned whether RAC has the expertise or the administrative capacity to handle a large flow of proposals from industry.

Anti-genetic-engineering activist Jeremy Rifkin was much in evidence at last week's meeting, notably for obtaining a court order barring RAC from holding a closed session to discuss a deliberate-release experiment proposed by Advanced Genetic Systems, Inc (AGS). The company is the sponsor of the planned release of frost-resistant bacteria by Steven Lindow of the University of California, Berkeley, currently tied up in other litigation initiated by Rifkin. AGS decided to submit to RAC its own proposal to conduct a similar experiment. In accordance with standard procedures for dealing with proprietary information, RAC announced a closed session to review the proposal.

At the behest of several RAC members, a decision was later made to open as much of the discussion as possible. Rifkin argued in his lawsuit that RAC did not have sufficient grounds to close any of its discussions of the proposal and that the subsequent decision to open part of it was not announced 30 days in advance in the Federal Register, as required for public meetings. A US Court of Appeals panel, acting on the technicalities of Rifkin's complaint rather than its substance, ordered RAC not to hold its discussion until it had published proper advance notice and had it explained why any portion of the discussion should be closed to the public.

Rifkin also appeared at the meeting to protest against a proposal from researchers at Uniformed Services University of the Health Sciences to lower the containment required for a previously-approved experiment aimed at cloning the gene of a bacterial toxin responsible for dysentery. Rifkin, claiming the support of several prominent arms-control experts, said the experiments should not commence until an "Arms Control Impact Statement" was prepared on the research. The Arms Control and Disarmament Agency is charged by Congress with preparing such a statement on any government research with potential military applications.

Rifkin said these experiments could be used to create biological warfare agents, and that RAC members "would be personally liable under international law and the principles enunciated at Nuremberg in aiding the commission of crimes against humanity" should the work lead to biological weapon development.

Paul Warnke, former SALT negotiator and the first name on the list of supporters claimed by Rifkin, said in an interview that he had not endorsed Rifkin's remarks, but had only told Rifkin in a telephone conversation that he believed an impact statement would be important in judging the implications of the research. He said that he neither supported nor opposed the actual research.

Proponents of the experiment, which was approved by RAC last year at P4 containment, said the research was vital to the development of a vaccine against the leading cause of dysentery. RAC approved the request to lower the containment requirement to P2 by a 9 to 5 vote with 4 abstentions. The director of the National Institute of Allergy and Infectious Diseases, to whom RAC reports, has generally declined to accept recommendations made on split votes such as this one.

Stephen Budiansky

Australian technology

Tax perks the stimulus

Canberra

AUSTRALIAN investors and technologists are likely to benefit from the Management and Investment Companies Act that came into force at the beginning of this month. The act embodies a tax-deductible venture capital scheme designed to bring together investors, innovative small businesses and management and investment companies (MICs). A licensing board, appointed by Mr Barry Jones, Minister for Science and Technology, is to select about eight MICs from the large number of expected applicants and to approve the amount of tax-free capital each can raise.

The MICs will choose several small, local high-technology businesses which they believe can sustain an annual sales growth rate higher than 20 per cent over the next three years. They will supply the businesses with long-term equity, loan capital and entrepreneurial advice, especially in marketing and finance. The source of the venture capital supply to the MICs will be investors who may claim 100 per cent tax deduction on the capital subscribed in the year of the investment.

Like Britain, Australia has done poorly in bringing technological innovation to commercial success: the technologists blame the businessman's conservatism and financiers blame the inventor's lack of management skill. The MIC scheme is based on recommendations of the Espie committee, set up by the previous government to investigate ways of financing high-technology enterprise in Australia. The committee perceived a gap at the high-risk, high-return end of the Australian capital market. The scheme may go some way towards plugging it. As if to fend off the possible jibe that a business with sales expanding at more than 20 per cent a year needs no special assistance and that the gap is merely the embodiment of Australian lack of self-confidence, Mr Jones recently echoed the Espie committee's remark that it "knew of no country which had succeeded in establishing a climate for investment in high technology without the government taking positive action".

The first MIC licences are expected to be granted in April. Over the first five-year period of phased capital injections into the ventures, $A200 million will be licensed for subscription to the MICs, at an estimated tax revenue loss of $A100 million.

On 24 January, the Treasury altered the proposed tax-incentive schedule for investors to promote long-term "patient" equity investment in the MICs and to inhibit abuse of the scheme. Investment for less than two years now attracts no net tax deduction; for the full, 100 per cent deduction, a four-year investment is necessary.

Soviet Union

Orlov's fate in balance

Dr Yurii Orlov, the Moscow physicist and human rights campaigner, last week completed a seven-year prison sentence for slandering the Soviet system. Ironically, the expiry of his term (on 10 February), coincided with the announcement of the death of the Soviet leader, Mr Yurii Andropov, who at the time of Orlov's trial was head of the secret police (KGB). Dr Orlov is now due to serve a further five years in Siberian exile. Last week, however, his supporters in London and Geneva announced proposals aimed at ameliorating the remainder of his sentence.

At his trial, Dr Orlov openly admitted charges of circulating and distributing to the Western press documents alleging breaches of the Helsinki accords and international human rights conventions within the Soviet Union. The basis of the prosecution case was that these allegations were false. However, Mr John Macdonald, who failed in his attempts to travel to Moscow to serve as Orlov's defence lawyer, still maintains that they were true, and last week, at a press conference held at the Institute of Physics in London, announced his intention of petitioning the Soviet courts to reopen the case on the grounds that much pertinent defence evidence was never considered. Such a petition has little chance of succeeding because Mr Macdonald's proposed witnesses are either citizens of Western countries or else recent emigrants from the Soviet Union — people whose motives would be suspect from the Soviet point of view.

A more realistic proposal is a petition that Dr Orlov's "internal exile" be commuted into "external exile", that is, that he be sent abroad. One suggestion is that he could be offered a job at the European Organisation for Nuclear Research (CERN) with the LEP (large electron-positron) storage ring project. The governments of the thirteen member-states of CERN have been unofficially canvassed, and most of the replies so far received have been cautiously supportive. CERN has, incidentally, a long-term cooperation agreement with the Soviet Union which was extended six months ago, and which includes work on LEP.

As to Orlov's scientific fitness for such a job, this was beyond dispute before his imprisonment, and it is known that he has tried to keep up his scientific work while in the prison camp, although, after a few early letters (an extract from one was reproduced in facsimile in *Nature* **277**, 591; 1979) the camp censors clamped down on anything resembling a scientific equation for fear it could be a coded message. If he is, indeed, sent to Siberia, Mr Macdonald has suggested that scientists from CERN should apply for visas to visit him — and if refused should consider some form of "non-cooperation" with the Soviet Union. CERN has a vigorous "Orlov Committee" whose activities have included defence of scientists in Uruguay, Turkey, Morocco and Poland as well as the Soviet Union, mustering on occasion over 600 signatures out of a scientific workforce of 3,500. This committee supported Mr Macdonald's proposal but stressed that each individual must decide for himself the "appropriate" response to a refusal. (Ethics apart, it would make no sense for one solitary member of a large team to opt out of a joint project.)

Finally, Mr Macdonald suggested the establishment of a $50,000 annual "Orlov prize" for the defence of human rights, for which he would approach the Rockefeller Foundation in the United States for funds. The CERN Orlov Committee again approved the idea in principle but suggested that it should be funded either by a consortium of European universities or by neutral governments such as Sweden and Switzerland, since the backing of these bodies would disarm possible Soviet criticism that the prize was simply a capitalist propaganda ploy.

At the time of writing it is uncertain whether Dr Orlov has been released from prison. Soviet legislation provides for an extension of sentence if prison rules are contravened and Dr Orlov has already lost visiting and correspondence rights for alleged contraventions. **Vera Rich**

West German universities

The price of protest

Bublingen, West Germany

A protest in West Berlin last week by 90 university lecturers against the siting of Cruise and Pershing missiles in West Germany, in defiance of instructions from the presidents of the Free University and the Technical University, was echoed at a conference here organized by the anti-*Berufsverbot* campaign. *Berufsverbot* — the exclusion from employment in the government service of those whose political views are deemed to present a threat to the state — has been practised in West Germany since the early 1970s.

The procedure is deemed by many constitutional lawyers to be contrary to the guarantees in the West German constitution of civil liberties and freedom of conscience. The practice was authorized by a special decree of the federal government, and has never gone through the parliamentary law-making procedure. Its implementation varies in the different *Länder*, and in Hesse, where the Greens hold the deciding vote in a hung parliament, they are pressing for the practice to be dropped altogether.

The new development since the last anti-*Berufsverbot* conference in Hannover in 1982, the campaigners say, is that restrictive measures have been increasingly employed against peace campaigners. There were complaints that the practice of *Berufsverbot* has been supplemented by restrictions on demonstrations and penalties for those taking part on the grounds of public order.

Surprisingly, and in contrast with previous conferences, there was little to report this year from the university sector. University lecturers and schoolteachers, being paid by the state, are considered to be "public servants". One view is that all lecturers at risk have already been sacked, while new graduates with doubtful political views are unable to gain university employment.

The only striking new *Berufsverbot* case affecting the universities reported at Bublingen was that of Hans Joachim Wunderlich, a mathematician who was dismissed last year from the Karlsruhe University Computer Centre on the grounds that he constituted a security risk, since the computer was also leased for defence-related industrial research. So far, university staff taking part in peace activities have not been penalized. This contrasts sharply with school teachers, many of whom are now facing disciplinary proceedings for taking part in the "five-minute strike" for peace organized by the Trade Union Federation (DGB) on 5 October 1983, or for allegedly "over-emphasizing" the theme of peace in school projects and concerts.

The universities have not been directly affected by the "Strike for Peace" because it took place on a Saturday (in West Germany a working day for schools but not for universities). The Berlin protest may be different. **Vera Rich**

La Palma's Newton

The Whirlpool Nebula (M51) as seen by the United Kingdom's 2.5-m Isaac Newton Telescope, newly erected at the La Palma Observatory in the Canary Islands. The official "First Light" was received by the telescope on 13 February.

Remote sensing/mapping

Call for UK investment

THE remote sensing market is an essential area for UK involvement, according to a report on *Remote Sensing and Digital Mapping* (HMSO, £7) produced last week by the House of Lords Select Committee on Science and Technology. And while the government is asked to increase investment in selected areas, most of the report's 52 recommendations concern changes in the infrastructure of the remote sensing and mapping communities. In particular, there is a call for greater effort in the handling and intepretation of digital data and the development of a network of linked computers in key centres.

The committee highlights the market potential of remote sensing, especially the current investment in the United States and France in satellite imaging systems. A major recommendation is that the National Remote Sensing Centre at the Royal Aircraft Establishment, Farnborough, should be given more staff and become the central "executive" node of a national computer network — a role similar to that of the Rutherford Appleton Laboratory in the astronomers' 'Starlink' network.

The aim would be to enhance the general accessibility of remote sensing data. The committee emphasizes that a significant challenge for the future will come not so much from advances in satellite instrumentation (although increased spectral resolution and radar sensivitity are two key areas of research) but through the sheer volume of data that such technical advances will produce. Two areas of strength, therefore, on which the United Kingdom should build are remote sensing radar and software development.

On satellite vehicles themselves, the committee advocates enthusiastic participation in European Space Agency projects such as ERS-1 — a remote sensing satellite due for launch in 1986 — but also bilateral collaborations, particularly with the United States and Canada.

Another important recommendation is that there should be a formal link between the research councils in the form of a joint committee for basic research. This is likely to be welcomed by those working on the proposed Satellite Radar Altimetry project (see *Nature* **306**, 108; 1983) now under consideration by the Natural Environment Research Council and the Science and Engineering Research Council. The project is not only costly (requiring about £18 million over ten years) but also falls within both councils' areas of responsibility, and, as a result, has encountered difficulties. Yet its supporters argue that it would incorporate the development of just the sort of expertise in instrumentation and data-handling that the House of Lords committee seeks.

Philip Campbell

● The report also concludes that the Ordnance Survey should increase its qualified research and development staff if it is to maintain its leading role among British mapping agencies and that the survey's digitization programme should be speeded up.

These conclusions will be as music to the ears of Ordinance Survey staff, who have been facing an uncertain future. Formally, the survey is a government department financed on a vote from central funds. A plan last year to re-establish it as a "trading fund" met with a chorus of protest from a variety of Ordnance Survey users, and was defeated in the House of Lords. Last month Mr Patrick Jenkin, Secretary of State for the Environment, announced that the survey will remain on voted funds but will be required to work to clearly defined financial targets.

The digital mapping programme is very much in its infancy but the committee believes — and some at the survey are ready to agree — that demand for digital maps is likely to increase because they can be displayed or printed very rapidly, to a variable scale and with user-defined edges. Moreover, particular features can be emphasized, or omitted for clarity, and digital maps are easily updated.

The committee wants a reversal of the recent "insensitively applied" manpower cuts of almost 25 per cent in five years. As a second best, even more of the digitizing work should be contracted out than at present, to make savings which would then pay for extra staff. In this way, the Ordnance Survey could become a national centre for digital mapping incorporating a development team headed by a chief scientist.

But the House of Lords committee does see some difficulties on the horizon. Perhaps the most important is that of copyright. For many years, some small societies, such as the Chiltern Society, have been selling their own annotated versions of Ordnance Survey maps. But, in keeping with its new business-like image, the survey will not allow the sale of such competing maps in areas where it has produced an adequately detailed series of its own. With digital maps the problems may be much more difficult: the Ordnance Survey supplies base data from which any number of maps may be produced and which may be continually updated. Their Lordships decline to offer a solution to the problem.

Tim Beardsley

Correction

SIR Peter Hirsch's share of the 1983–84 Wolf Foundation prize in physics was for his contributions to the utilization of the transmission electron microscope and not the scanning electron microscope as claimed in *Nature* 2 February, p.407. □

Czechoslovak science

Large gap to bridge

PLANNERS in Czechoslovakia must reject slogans about the "omnipotence" of science and technology, since these can foster "dangerous illusions", deputy federal premier Jaromir Obzina warned last month. He was addressing the first meeting of the new State Commission for Scientific, Technical and Industrial Development, set up to close the gap between research and development on the one hand and the practical implementation of results on the other.

Before the establishment of the Czechoslovak commission, there had been considerable discussion in the press about the reasons for the gap. The general opinion was that there is no serious lack of funds for research — indeed, some allocations are not taken up or spent in full. Instead, the main cause appears to lie in the personalities of those responsible for implementing the results, a view reiterated by Mr Obzina in his reference before the comission to "insufficient coordination" between research and production and to "serious shortcomings" in management.

The purpose of the commission, Mr Obzina said, is to reveal the real causes of the shortcomings, and to deal with real problems. Energy should not be wasted on theoretical "pseudo-problems" and discussions, "however brilliant and witty they might be". But the task, he implied, is likely to be a long haul. The process of "socialist industrialization" may be compared with collectivization in agriculture — "a programme of persistent work for a number of decades".

He warned the commission against associating itself with "naive people" who "today enthusiastically applaud scientific and technical progress", but whose personalities lack "persistence, diligence, perseverance and selflessness". Such people, he said, will be all too likely to turn against science when they find that "no cheap results have fallen into their laps".

Such remarks must, of course, be politically irreproachable, coming as they do from a deputy federal premier with the endorsement of party presidium member Milos Jakes, who pledged to the commission the "effective support" of the party "at all levels". In another context, and from a less eminent speaker, they might be construed as containing a certain veiled criticism not only of Marxism (which bases its validity on its "scientific" nature) but also of the Soviet Union where, during the later years of the Brezhnev era, there was undoubtedly a tendency to expect, in Obzina's words, "some kind of miracle" as a result of that continuously repeated slogan "accelerated application of scientific and technical research findings in practice".

Nuclear waste

UK procedures condemned

THE Nuclear Installations Inspectorate (NII) and the Department of the Environment (DoE) this week publish separate, highly critical reports of safety procedures at the British Nuclear Fuels Limited (BNFL) reprocessing plant at Sellafield (formerly Windscale). The reports investigate incidents at the plant last November that led to widespread radioactive contamination and a public warning from the Department of the Environment against the use of beaches in the area.

BNFL's latest problems began on 11 November, when operators pumped wastes into a sea discharge tank, apparently unaware that radioactive solvent and "crud" had not first been separated off. Standing instructions for the procedure, which was being undertaken as part of the annual shut-down, were "ambiguous", says DoE's radiochemical inspectorate, and the procedure for communications between managers was "inadequate, prone to error and not sufficiently formalized". Records were kept only in manual log books and instructions were confused by contradictory suggestions made in pencil.

As soon as the mistake was detected the flow was stopped. Attempts were then made to return the solvent and crud to the treatment plant, but because the available pipeline had only a 2-inch diameter, the procedure was partly unsuccesssful and the level of gamma radioactivity near the sea tank outlets necessitated evacuation of workers from the immediate vicinity of the pipes. By this time, senior management had been alerted and after further unsuccessful attempts to rescue the position they decided to flush the offending material down the sea pipeline to increase flow rates and reduce radiation dose to workers. DoE says this decision was taken "without adequate assessment of the available options": the presence of the solvent and highly active crud "does not appear to have been considered".

The company did not at this stage inform the relevant government departments because the total amount of radioactivity in the sea tank was less than the total authorized discharge; DoE says the company "would have been well advised to do so". BNFL maintains that a high proportion of the 4,500 curies of beta activity in the sea tank was returned to the plant, but NII is sceptical and thinks "a significant proportion" went to sea.

The first indication of problems outside the site was on 14 November, when divers from a ship belonging to the environmental group Greenpeace were contaminated with ruthenium 106 in solvent. Two days later, a DoE inspector was informed that ruthenium had been released but was told neither of the complex circumstances nor that more than 500 curies was likely to have been released. On 18 November, BNFL noticed a slick of solvent at sea and attempted to disperse it, but subsequently lost the slick. The slick and associated debris were later washed up on the beach, but, according to DoE, BNFL had no effective procedure for recording and assessing results. On 20 November, BNFL advised the public that all was back to normal and that beaches could be used again. This was later contradicted by DoE, and BNFL's decision is now criticized.

DoE says that current authorizations are not adequate to deal with sudden releases of solvent and crud. Although the total amount of radioactivity released was well within authorized limits, the sticky nature of the solvent, together with the highly active crud, led to the formation of local "hot spots" of activity, mainly on flotsam, and these were the main potential hazard.

Although little damage to public health is likely to have resulted from the November incidents, there is more concern over plutonium that is routinely discharged and which, contrary to expectations when the discharge pipeline was built, appears to bind to sediments on the sea bed. DoE's radiochemical inspectorate considers that solvent discharges in the past may be responsible for the enrichment of plutonium in the sea surface and its subsequent transfer to land. The National Radiological Protection Board is investigating whether plutonium in household dust in the Sellafield area could account for a local excess of childhood leukaemias claimed in some recent studies.

NII has required BNFL to make a number of immediate changes to operating procedures, and further long-term improvements are planned. Automatic cut-offs have already been installed to prevent solvent or crud finding its way to the sea discharge tanks.

Both reports are now with the Director of Public Prosecutions. The DoE report finds possible breaches of statutory operating requirements relating to record-keeping and maintaining doses to the public that are as low as reasonably achievable.

Tim Beardsley

Seabed geology

Gloria goes west

IN a few weeks' time, the MV *Farnella* will sail for the west coast of the United States carrying the unique long-range sidescan sonar "Gloria". The voyage is the result of a new cooperative agreement between the Institute of Oceanographic Sciences (IOS), a component body of the UK Natural Environment Research Council, and the US Geological Survey. It will cost the latter over £1 million.

Gloria (Geological Long Range Inclined Asdic) will be used to survey the ocean floor in all waters more than 500 m deep within the Pacific margin of the recently created US Exclusive Economic Zone. The objective is to produce maps of the shape and texture of the seabed, the interpretation of which may reveal features of economic as well as academic interest.

Gloria was developed by IOS and is at present the only sonar of its type in the world. Using acoustic back-scattering in a manner analogous to the use of oblique illumination during aerial photography, the system produces images of the seafloor up to 30 km either side of the track of the 8-m long towfish. In its six years of service, Gloria II has mapped approximately one-fiftieth of the world ocean floor.

Geological interpretation of the Gloria data may provide clues to the petroleum potential of the Exclusive Economic Zone. Of equal interest is the possibility of discovering significant quantities of heavy metal sulphides. Hundreds of kilometres of the Gorda and Juan de Fuca ridges lie within the zone and the heat generated at these spreading centres causes large-scale circulation of seawater. This extracts elements such as manganese, zinc, copper, cadmium and silver from the fresh basalt and emerges on the seafloor as spectacular "black smokers". Contact with the cold ocean water causes precipitation of sulphide minerals which may build up economically attractive deposits.

The investigation will yield immediate returns for the academic community but in commercial terms it must be seen as a speculative investment. **Peter Gambles**

New man at zoo

BARRING the unlikely emergence and the even less likely victory of an alternative candidate, Sir William Henderson FRS will succeed Lord Zuckerman as president of the Zoological Society of London. Sir William, a former secretary of the Agricultural Research Council, sees his most important task as reducing the society's budget deficit, now running at £2 million a year. The society has long been plagued with financial problems and many zoo buildings need renovating. Last year, the Department of the Environment turned down an ambitious expansion plan but agreed to write off the society's losses to the tune of £2 million a year until 1986.

Sir William is keen to preserve and enhance the society's scientific prestige: its expertise in reproductive physiology, for example, has allowed it to maintain in captivity species such as the oryx that are almost extinct in the wild. The only way to continue to finance such work will be to increase the number of visitors to the zoos.

Unesco

Turmoil and strife abound

Paris

THE science and technology programmes of the United Nations Educational, Scientific and Cultural Organization (Unesco) are putting a brave face on the threatened withdrawal of the United States at the end of the year. Indeed, there is even a possibility that for the next few months, science and technology, which have often been pleaded in aid in the past year, will be more generously dealt with.

One sign of this is that the annual grant to the International Council of Scientific Unions has been increased by a quarter to $500,000 for the year ahead, exclusive of contracts yet to be agreed. But Unesco's generosity will also take in for the first time the World Federation of Scientific Workers, which is to receive $5,000 or more to support its newsletter.

How the total funds for science and technology will be affected will be known only when the urgent review of the budget now under way is decided, in early April. The management has asked for a 10 per cent reduction, but this will not be equally spread. Much the same will happen to vacancies as they arise. Posts will be left vacant if possible but otherwise filled by transfers within Unesco.

Much change is in prospect. The much respected head of the Man and Biosphere Programme left earlier this month for the University of Montpellier. The Belgian head of the Science Policy Division, the work of which was criticized at the biennial General Assembly last year (particularly by the British), will retire later this year. It will be a test of Unesco's managers' mood to see whether that vacant post is filled. One other senior departure seems in the offing at least, but there is talk of a senior Soviet scientist joining.

The mood among the staff ranges from optimism to despair. Some see the director-general's attitude as intransigent, fear their life's work is being jeopardized — "It's just as much my Unesco as his" — and fear that prospects of promotion are blocked. Others consider that less money may encourage efficiency and point out that their financial contribution to outside activities such as training is often only token and could be further reduced without catastrophe.

Some administrative problems are as yet unsolved. For many collaborative projects, the United States provides not only its general contribution but also assistance in kind — research vessels, communications and administration. So will US agencies be allowed (or wish) to continue if withdrawal goes ahead?

The charge of bureaucracy levelled at Unesco is impossible to verify or deny. Some say it is a mess, others point out that repeated enquiries from member governments make endless work, as do the endless committee meetings at which a Unesco presence is thought necessary. More worrying are the sudden if small shifts of policy at the behest of top management or if an itinerant official should rashly promise to help a host government.

One impression is that Unesco's most serious problem in science and technology is that it expects its staff to behave as scientists when they are administrators, that the organization is as a result too ready to make judgements off its own bat without the benefit of external advice, and that the endless search for programmes that sound well often blinds it to projects it could usefully tackle. **John Maddox**

US medical schools

Admissions coaching challenged

Washington

THE administrators of the standard test for admission to US medical schools are taking new legal action to prevent a Pennsylvanian company from using bootlegged copies of past tests. The Association of American Medical Colleges (AAMC), which owns the standard Medical College Admission Test, or MCAT, charged in federal court last week that Multiprep, a company that offers to prepare students for MCAT, had reproduced questions from the tests verbatim in its course materials in violation of copyright law.

Multiprep is one of many small organizations offering coaching courses for students planning to take college admissions tests, such as MCAT, that tend to weigh heavily in admissions decisions. The test administrators' standard line has been to discount the effectiveness of such courses, which typically cost several hundred dollars, but otherwise to view them as a tolerable nuisance.

Last June, however, AAMC noticed that 250 students from the Philadelphia area who took MCAT in April 1983 did particularly well on questions that had been recycled from the test given in autumn 1980. Further investigation revealed that all had taken the Multiprep course. AAMC obtained a court order to have Multiprep's offices raided; on the basis of materials seized by federal marshals in the raid, including exact copies of MCAT question papers, AAMC was then granted a temporary injunction against Multiprep pending a trial on the merits of the copyright violation charge. The injunction specifically barred Multiprep from using MCAT materials or from advertising, as it had, its possession of "facsimile" MCAT tests.

In last week's action, AAMC claimed that Multiprep had violated the court order on both counts. AAMC said that 77 of the 87 chemistry and biology questions appearing in Multiprep's current course materials were word-for-word copies of MCAT questions.

According to AAMC, questions are "often" repeated from year to year in the test both for statistical reasons and because of the limited number of "quality" questions covering first-year college material in biology, chemistry and physics. The test administrators take pains to prevent the circulation of test questions; question papers are numbered serially and are collected and checked after each administration of the test. AAMC officials believe that Multiprep obtained their material by having an examinee remove the inner pages of a test booklet, replacing them with dummy pages.

No date has been set for the trial on AAMC's original accusation of copyright infringement, in which AAMC is seeking $1.5 million in damages against Multiprep. **Stephen Budiansky**

Accident casualties

ROMANIA's Minister of the Chemical Industry, Gheorghe Caranfil, and his deputy, Ion Bivoralu, were sacked last week as a result of a major accident last December in the pyrolysis installation at the Teleajen petrochemical combine. A joint party and government commission found that the accident was due to "serious deficiencies" in the organization and management of the pyrolysis installation during its commissioning, violations of safety regulations and "serious violations" of order and discipline. The Communist Party Secretariat of Prahova County (in which the Teleajen plant is situated) was rebuked for failing to take "appropriate political educational measures" to ensure the smooth operation of the plant, and the first secretary of the county party committee, Virgil Cazacu, and also a deputy prime minister, Ion Nicolae, received votes of censure.

No details of the accident have been published, but the tone of the official announcements, with their repeated use of the words "grave" and "serious", as well as the penalties imposed, point to major human and financial loss.

The petrochemical industry is a particularly sensitive issue in Romania. Mrs Elena Ceaucescu, the wife of the party leader, is herself a petrochemical engineer, and, as head of the National Council for Science and Technology, was responsible for the expansion of Romania's petrochemical capacity in the early 1970s — a programme which caused Romania, an oil-producer, to become a net oil importer, and which has been a major cause of the country's present energy problems. Palaeontology

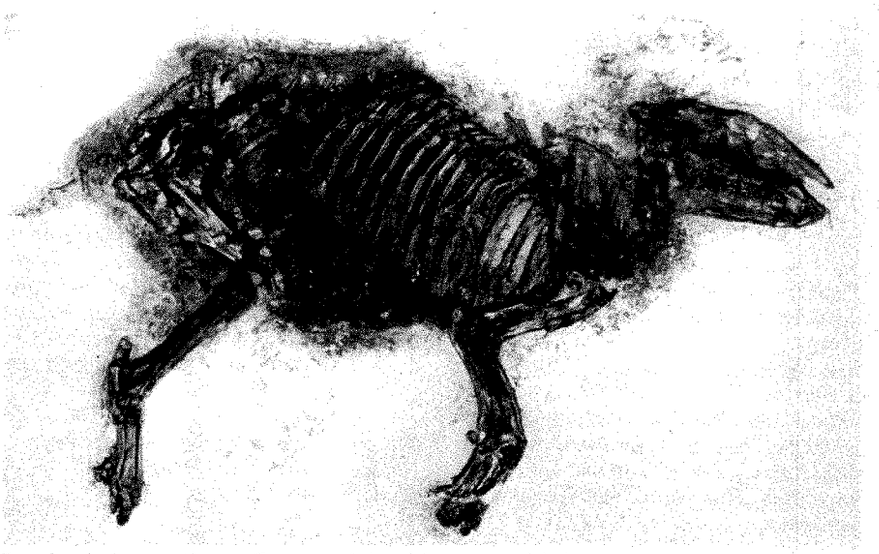
New bones for old

AFTER 12 years of planning and legal battles, one of the world's top ten palaeontological sites — at Messel, near Darmstadt in West Germany — has been designated a rubbish dump. The decision, which will not be immediately disastrous, is a compromise between the obligation of the local bureau of mines to deal with dangerous old mine workings and the scientific community represented principally by the Senckenberg Museum in Frankfurt.



The main site covers about 10 per cent of a 90-year-old opencast mine working in soft oil shale that forms a pit 1 km long and 60m deep. An entire Eocène ecosystem is preserved with a huge variety of fossils of outstanding quality.

The first fossil, a crocodile, was found at Messel in 1875. Between 1886 and 1971, some 20 million tonnes of oil shale were mined. As the mining decreased in the 1960s, the pit became the focus of a rush of amateur fossil hunters. It was eventually closed to the public because of its dangerous state but, with a five-year grant from the Volkswagen Foundation, scientific excavation began in 1976.

To preserve the complete site permanently for palaeontologists would cost DM30 million (£7.5 million) on one estimate, a sum that could not be found by the mining authority of the *Land* of Hesse which has legal responsibility for the site. It has therefore decided that the pit will be filled with waste, although about 40 per cent of the area will be preserved for 20 years for scientific work, and an extra 9 hectares will be made accessible for a period of a year or two while drainage is carried out.

The site is the product of two rivers which bore detritus into a warm (20-30°C) still lake over a period of 1-2 million years. The oil shales preserve not only the contents of the lake but also the flora and fauna of the teeming palm forests that lined its margin. The fossils contain 40 per cent water and were difficult to preserve until the advent of replacement techniques using water-miscible plastics. These reveal skeletons and unique soft-part detail, fine enough to show replacement of many structural parts by bacteria and including feathers and hair. Stomach contents show, for instance, that the bat *Palaeochiropteryx tupaiodon* lived primarily on Lepidoptera and that the horse-like *Propalaeotherium* ate foliage including bay leaves and vines.

Every major group of the animal kingdom is represented at Messel and published papers already fill more than 130 monographs issued by the Senckenberg Museum. Finds have included many rarely preserved amphibians, skeletons of bats with hair and skin, a unique rodent genus and, last year, an anteater never before unearthed in Europe and indicative of later land links with America than has hitherto been supposed.

Propalaeotherium messelense, *a European relative of the ancestor of the horse.*

Given the legal position whereby responsibility is a matter solely for *Länder* government, even though most of the research on the site is supported by federal agencies, those involved have reluctantly accepted what appears to be the best compromise. The argument that Messel is so important that it should be designated by the United Nations Educational, Scientific and Cultural Organization as a site of special historical interest neglects the legal fact that an initiative in that direction would have to come from the *Land* of Hesse. □

Israeli Arabs

Finding technical jobs

Rehovot

FEW Israeli scientists can claim to have declined the offer of a job overseas in favour of one at one-quarter of the salary at home; even fewer are Arabs. One who fits both bills is Dr Nicola Yanaki, a nuclear physicist whose decision to work for one of Israel's most successful high-technology companies was made, in part, to help fellow Israeli Arabs.

Yanaki, who lives in the predominantly Jewish town of Upper Nazareth, is product manager for mammography at the Elscint plant in that town and is largely responsible for the company's advanced systems for the detection of breast cancer. Called Man 2 and Man 3, they provide extremely fine resolution and optimal contrast for accurate differential diagnosis.

Yanaki grew up in the town of Ramle, near Tel Aviv, and received his first scientific training at the Arab Orthodox College (a high school) in Haifa. He then went to Tel Aviv University, where, in August 1981, he became the first Israeli Arab to win a doctorate in nuclear physics. During his stay at Tel Aviv University, Yanaki developed and patented a special gamma-radiation detector. This device, while not yet produced commercially, aroused interest among oil companies because it has proved useful in oil exploration projects.

Indeed, it was because of this detector that a US oil company offered Yanaki a well-paid job, which he turned down when asked to join the staff of Elscint, which now sells $110 million worth of medical imaging equipment a year. Yanaki clearly feels that he should repay the nation for having provided him with a good education, as well as being motivated by a desire to help other Israeli Arabs. Those with advanced training in science and engineering have limited employment opportunities because many science and engineering jobs are in defence industries and hence, Yanaki says, "are naturally closed to Arabs in present circumstances".

Until these circumstances change, Israeli Arabs with Yanaki's background must look to civilian science-based industry. By taking a job with Elscint, Yanaki feels that he has "opened the way for others". At Elscint itself, this is clearly the case. There are two Arab engineers in Yanaki's own staff, and another Arab, Anvan Nujam, is carrying out research in Elscint's ultrasound division.

At a time when many others are pessimistic about the chance of peace in the Middle East, Yanaki is optimistic, pointing out that the people of the region have everything to gain by working together. He looks forward to the day when he and his colleagues at Elscint will be able to work on joint projects with researchers in neighbouring Arab countries. And, he adds, "I'm sure that day will come more quickly than anyone now believes possible".

Human experiment

SIR — The relative rarity with which the results of experimental work in human beings are reported in *Nature* must be the excuse, if not a good one, for the publication of a study on pain in which (1) no indication of whether consent was sought is given (and the study design probably excludes the possibility); and (2) pain experienced by individuals was *increased* by the experimenters' hidden actions. ("Placebo and naloxone can alter post-surgical pain by separate mechanisms", by R.H. Gracely *et al.*, *Nature* **306**, 264-265; 1983). Although dental pain may be regarded as trivial, I, and I am sure many of my colleagues, would regard this study as unethical by any standard.

H.A.F. DUDLEY
Academic Surgical Unit,
St Mary's Hospital,
London W2 1NY, UK

● R.H. GRACELY REPLIES — Professor Dudley's letter challenges whether consent was obtained and the ethics of giving a drug that may increase pain. It is unfortunate that the consent procedure was not described in the text. Human research protocols at the National Institutes of Health (NIH) must be approved by a formal review process that includes written informed consent. In this case, the consent form indicated that "withdrawal from the study may be accomplished at any time without jeopardy or prejudice" and informed the subjects that they may receive "a maximum of 10 mg naloxone — a drug that may be less effective than placebo in pain relief and that theoretically may increase any pain". Professor Dudley is correct in citing this omission from the manuscript but he inappropriately suggests that this study could be performed without consent.

His description of this study as unethical is a more serious matter. He criticizes not only our ethics, but those of other investigators. A dose of 10 mg naloxone has been administered to dental patients after third molar extractions in several highly publicized studies, including one published in *Nature* (**272**, 826-827; 1978). The increase in pain after naloxone administration was slight and caused no excessive discomfort in these experiments. Our use of naloxone was accompanied by knowledge of its effects in previous studies and by an informed consent procedure that included termination at any time. Patients not only completed this study (involving extraction of third molars on one side) but returned for a similar extraction of their contralateral third molars. They described the naloxone experiment as uncomfortable but tolerable.

Professor Dudley is apparently unaware of the previous studies assessing the effects of naloxone on postoperative dental pain or of the magnitude of the naloxone effect. Naloxone causes a minimal and temporary increase in discomfort in this situation. However, a great majority of human medical research involves discomfort and risks. It is not the presence of these factors but their magnitude, along with important issues of consent and voluntary termination, that are of ethical concern. The discomfort and risk in this experiment were considerably less than those experienced in many routine medical studies. Unfortunately, Professor Dudley has not addressed previous studies (cited in our article) or the relative magnitude of the discomfort, and has also questioned the research policies at NIH.

Placebo defect

SIR — A recent light-hearted account of the banning of urea foam insulation in Canada (*Medical Post*, 15 November 1983), has drawn attention to the lack of a word in the English language to describe the opposite of a placebo. A placebo may be defined as something which, in itself, is inactive, such as a simple lactose pill. However, a placebo has been found to be effective therapeutically in about 30 per cent of patients suffering from a wide spectrum of diseases.

Little attention has been paid to the possibility that a harmless substance produces harmful effects when the patient believes it to be toxic. The author of the article in *Medical Post* suggests the word "garblow". The urea foam insulation was banned precipitately by the Government of Canada after a media crusade against the "dangerous" formaldehyde gas which the insulation may emit. Of about 80,000 households which had installed foam insulation, about 10 per cent developed symptoms which they were encouraged to attribute to the formaldehyde vapour. The English have learned to live with the particular peril of foam insulation but there must be many examples of garblow in our own press threatening our health and sanity.

Homer's wine

SIR — Wright and Cattley's chemical hypothesis about Homer's "wine-dark sea" (*Nature* **303**, 568; 1983) is both interesting and evidence of a commendable piece of interdisciplinary cooperation.

But the topic of Homer's epithet is many-sided. Any "solution" of the "puzzle of the wine-dark sea" will be a function of one's particular couching of the question. The chemical hypothesis would certainly be appropriate to the question "Why did Homer call the (Mediterranean) sea wine-coloured (he mentions only red wine in his epics) when it is celebrated for its blueness?" The hypothesis that adding alkaline water to the wine of Homer's time and region turned it from red to blue complies with the scientific requirement of being empirically verifiable, in principle if no longer in practice. Yet a positive test result would not solve, or even invariably be appropriate to, other aspects of the puzzle unless one asserted reductionistically that a scientific answer is the "one proper" one.

Among the many other equally tantalizing aspects of the sea/wine topic are:

(1) Irrespective of the actual colour of the wine, should not the phrase "wine-dark sea" be seen purely or primarily as a formulaic device of the oral Homeric tradition, a recurrent epithet or a fixed metaphor? Homer uses it many times in diverse contexts in both the *Iliad* and the *Odyssey*.

(2) Should we doubt that the Mediterranean sea can look wine-red? The classicist Stanford and others have noted that it is at times a "deep purple crimson" or "mulberry" in places. So "wine-dark" could in fact mean "wine-red".

(3) How adequate, in aesthetic and/or other respects, are the various translations of Homer's original Greek phrase, namely οινοπα ποντον, to quote one inflexion? Down the ages it has been translated into several languages and with divergent meanings. Examples are "wine-dark sea" (Rieux, Shewring), *les vagues vineuses* (Bérard), *weinrote Meer* (Schadewalt), and *wijnkleurige zee* (Boutens). Among English translations, we have variations such as "wine-coloured sea" (Simcox), "wine-faced sea" (Cook) and even "the gloomy flood" (Cowper). The translator Cook, in fact, sees no colour connotation whatever in the original Greek phrase.

(4) If we focus on just one English translation, say "wine-*dark* sea", and consider it simply as an aesthetically piquant English phrase, then what is its poetic merit as such? This question entails the usual multiplicity of considerations of imagery, associations, allusions, euphonics, and phonetic symbolism, and decisions made in terms of facets of these criteria may scarcely be a function of what colour the wine was.

What happens in the mantle?

While it is generally agreed that continental drift occurs by the mechanisms of plate tectonics, the forces that drive these motions remain largely undescribed. But change may be on the way.

AFTER more than 20 years of contentment bordering on complacency, the theory of plate tectonics seems in for a bout of disputation that may be as fierce (and as entertaining) as that of the late 1950s, when geophysics was divided into the two camps of neo-Wegenerians and the conservative rest. That the continents move relative to each other is not now substantially in dispute, of course: the reality of that phenomenon, originally inferred from observations of the deep oceanic crust, is now within the range of direct measurement using radio interferometry. The contentious question now is what drives continental drift? And what, in any case, goes on in the mantle on which the tectonic plates appear to float?

One small sign of which way the wind is blowing can be seen in the note by D.P. McKenzie on page 616. Without saying as much, McKenzie deals with a point often raised by his Cambridge colleague, R.A. Lyttleton, in the past few years — how can the new orthodoxy account for the several recognized episodes of mountain-building in regions far distant from the places at which continents are colliding with each other, or where one plate is riding over another, as in the formation of the Himalayas and the Sierras?

On the standard view, the continents, with an average density of 2.8 g cm^{-3}, float on the more dense mantle beneath in the particular sense to which geophysicists have made us familiar — adjustments take place on a timescale comparable with that of the plastic deformation of the solid material of the mantle. What McKenzie now says is that the mantle material beneath continents may differentiate into dense and less-dense components just as it does beneath the Earth's great spreading oceanic crust. But beneath the continents, the lighter material is either added to the basement or intruded at high levels as horizontal basalt slabs. In either case, the result is to make blocks of continental material more buoyant than they would otherwise have been. The result, the numbers suggest, may be some kilometres of uplift.

Orthodox geologists should be content. Mountain-building other than that provoked by the more spectacular tectonic events is made explicable. So too is the occurrence near the surface of metamorphic rocks, some even derived from sedimentary material, which have obviously in their time been deeply buried. This was precisely the phenomenon that C.J. Allègre and his colleagues from the Institut de Physique du Globe in Paris were describing last month (*Nature* **307**, 17; 1984). Whether this simple notion will settle the long-standing controversy about the origin of the Colorado plateau is less certain, given the great pleasure it gives to orthodox geologists.

Meanwhile, it may be thought puzzling that such a simple idea as McKenzie's has not been put forward long before this. The explanation seems to be that geophysicists have been unduly impressed with the apparent constancy of the thickness of the continental crust, almost everywhere within 5 km or so of 35 km, and at the same time attracted by the simplicity of the notion that the continental crust is essentially primitive material which, once formed, remains on or near the surface. That some of it must do so is shown by the ages of the rocks of the ancient shield areas, exceeding 3,000 million years. But not everything is quite that simple.

Dr D.L. Anderson from the California Institute of Technology seems ready to make a more striking break with the new orthodoxy of plate tectonics (*Science* **223**, 347; 1984). Starting from his own recent analysis of the speeds of seismic waves in the upper reaches of the Earth's mantle, Anderson outlines a framework within which the entire standard model of what happens in the mantle might be recast. The observations show that seismic speeds vary from one place to another, as gravity anomalies are known to do, while there is the now long-standing expectation that the regions of continental crust will act as an insulating blanket for the mantle beneath, where the temperature should as a consequence be greater than that elsewhere. Briefly, low seismic velocities signal relatively high temperatures.

Part of Anderson's argument is that these lateral temperature gradients must have an important influence on what happens within the mantle. Few will dissent from that. So what happens to the standard view of what happens in the mantle and of what drives continental drift — the notion that the mantle is one huge pattern of thermal convection cells in which hot material rises (along the lines marked out by the spreading centre) and sinks as cold material where the edges of oceanic plates re-enter the Earth by the process called subduction at the continental margins (south-east Pacific) and at island arcs (western Pacific)?

The remarkable feature of this convection process is that it has been so vague. If the present disposition of the continents and of the plates on which they are mounted is simply to be explained by a pattern of convection cells, at least some features of that pattern must have persisted for some 180 million years, the age of the oldest rocks so far found in the oceanic crust (in the south-east Pacific). So one would expect that the outlines of these convection cells would by now have been fully described, and the outlines of their ascending and descending walls drawn out on maps as befits important influences on the surface structure of the Earth. Then, by comparison with some theory of convection, it should be possible to tell what fraction of the driving force is represented by the thermal energy of the Earth's interior and how much by other influences. But in reality, even the depth of the supposed convection cells has been uncertain, although the discontinuity of seismic velocities at 670 km has been most people's favourite candidate.

Anderson's view of the upper reaches of the mantle is radically different. First, he says, it is not even vertically homogeneous but, rather, layered, as would be expected for a large body of material that has undergone continual zone-refining over aeons. The zone-refining consists of the liberation from the deeper rocks of those components which form liquids, or which can melt, and, on the same view, the buoyancy of the molten material is what drives upward convection. The apparent discontinuity of 670 km is not a phase transition within chemically homogeneous material but a region where both chemical composition and physical properties are changing.

If this way of describing what happens in the mantle proves correct, the consequences will be interesting. First, mantle convection need not be a continuous process but may be episodic — indeed, Anderson argues that the fragmentation of Gondwanaland may be most simply understood as the consequence of the accumulation of heat beneath it, setting off the instability that has continued ever since. And — this is the real radicalism — the occurrence of positive gravity anomalies may not be accidental but, instead, a sign that one consequence of mantle activity is that the Earth's moments of inertia can be changed so as to reorient the mantle as a whole with respect to the spin axis of the Earth. **John Maddox**

Vision

An old illusion and a new theory of stereoscopic depth perception

from John P. Frisby

OGLE'S induced effect, a visual illusion first studied in the 1930s[1], has over the past year been the subject of an intriguing series of papers[2-5] (the latest of them in this issue of *Nature*, p.632). The reasons for the renewal of interest in the induced effect can be found in the severe challenge it poses for conventional theories of binocular depth perception and the development of a new computional theory of stereoscopic vision within which it can be encompassed.

Stereoscopic depth perception is generally accepted to derive from the slightly different horizontal positions from which the two eyes view the world — small differences arise in the horizontal positions of corresponding points in the left and right retinal images of objects lying at different distances. But Ogles's induced effect is a change in depth perception caused by introducing vertical, not horizontal, disparities between corresponding points in the two images. The effect is usually produced by placing a meridional size lens, which has the property of magnifying an image in one axis only, in front of one eye such that it enlarges the image in the vertical dimension. As this magnification does not affect the horizontal axis, the lens should have no effect on the perception of depth, given conventional theories. In fact, however, depth perception is markedly altered. For example, a fronto-parallel surface appears rotated about the vertical axis through the fixation point, seeming to protrude towards the observer on the right-hand side if the right eye's image is vertically magnified.

Ogle called the illusion the induced effect because it seemed in many ways as if the vertical magnification 'induced' a whole-field magnification of the other image (or its neural representation)[1]. This compensated for the vertical size difference introduced by the lens but at the price of creating a horizontal size difference between images which then produced the illusory rotation via the normal mechanisms of stereoscopic vision. Gillam and Lawergren[2] provide a good review of the attempts of Ogle and others to explain the induced effect.

Recent interest has centred on the relevance of the induced effect to a new computational theory of binocular depth perception advanced by Mayhew and Longuet-Higgins[3-5]. The theory was not specifically designed to account for the effect but it predicts its occurrence as an inevitable side effect for any visual system that implements the theory. The fact that the human visual system is susceptible to the induced effect can thus be regarded as evidence that it contains mechanisms which implement the theory, a claim which has caused some controversy.

The new theory is based on a geometrical analysis of the spatial distribution of horizontal and vertical disparities. Figure *A* shows a symmetrically converged pair of eyes observing a square lying in the fronto-parallel plane containing the fixation point. Because the sides of the square are at different distances from each eye, each image of the square is a trapezium. Figure *B* shows how the two images possess horizontal (H) and vertical (V) disparities, defined respectively as the difference in x and y coordinates of matching points. It can readily be appreciated from the figure that the larger the observed square, the larger will be H and V: in other words, H and V will be scaled by retinal eccentricity. It is also true that H and V will vary with the fixation distance (d) and the angle of gaze (g; see figures *C* and *D*) with which the fixation point is viewed because both d and g will affect the relative sizes of images in the two eyes. The equations derived by Mayhew[3] that determine the relative contributions of these factors are:

$$V = \frac{xyI}{d} + \frac{ygI}{d}$$

$$H = \frac{x^2I}{d} + \frac{xgI}{d} + \frac{zI}{d^2}$$

where I is the interocular separation and z is the depth relative to the fixation point (both in centimetres; all other quantities in radians). Note that the z term in the equation for H reflects the fact that H values are sensitive to depth differences in the scene, which is why they provide the fundamental information for stereoscopic vision. In sharp contrast, V values have no z term: as a result they can be used to compute the viewing parameters d and g. With these parameters known it is then possible to interpret the ambiguous information in the equation for H and find the value of z: that is, it is possible to extract absolute values for depth differences in the scene being observed. Of course, all these computations depend upon the difficult problem of stereo correspondence having already been solved, that is, the problem of which points in the left image correspond to which points in the right image (for an introduction to this problem see ref.6, Ch.7).

The equations for V and H are remarkably simple and constitute a theory of binocular depth perception that shows that the absolute depths of all points in a scene can be recovered from visual information alone. Indeed the equations are so simple that, at least in principle, V values for only two matched points (of differing x eccentricity and not falling too close to the horizontal meridian) are required for the solution of two simultaneous equations in V to recover the parameters d and g. This is remarkable, because it has been a commonplace belief that d and g, so essential for interpreting the horizontal disparities, have to be obtained from extra-retinal information about eye positions. Curiously, although Helmholtz[7] knew that information about absolute distance was contained in vertical disparities, he gave no details and his comments have been neglected, perhaps because it has been assumed, incorrectly for near distances, that vertical disparities are too small to be detectable by the human visual system.

Why is it that Ogle's induced effect is produced as a side effect of implementation of the theory? It can be seen from figure *C* that V varies with retinal eccentricity in x, that is, the lines defining the top and bottom of the square become more and more separated as they extend into peripheral vision. Another way of saying this is that the vertical magnification difference between images is scaled by x, and a useful way of visualizing the equation for V is as a plot of the vertical magnification factor (given by V/y) against x. This graph is illustrated in figure *E*. It is a straight line whose slope is I/d so that, as I is known, the slope directly yields $1/d$. The reason why the slope is inversely proportional to d is that the further away the fixation point, the smaller will be the vertical size difference between images.

The intercept with the ordinate is given by gI/d, which means that it is scaled both by d and by g. For any given d, if convergence is symmetric ($g = 0$), then the plot goes through the origin; but if it is asymmetric ($g \neq 0$), then the line is shifted up or down by an amount proportional to g (fig. *E*). Changes in g do not alter the slope of the line and hence do not have to be taken into account in the computation of d from the gradient of change in vertical magnification with x eccentricity.

Consider now what happens if one image is vertically magnified. This will not alter the slope of the line but it will add a constant to the quantity V/y present at each x eccentricity, thereby reproducing the state of affairs for a non-zero gaze angle. Hence, a vertical magnification of one image will be interpreted as indicating asymmetric convergence. And by some straightforward algebra it can be shown that, if the pattern of H values created by a frontoparallel surface viewed with $g = 0$ are found to be present when $g \neq 0$, then they must have arisen from a surface rotated about a vertical axis through the fixation point. Hence any visual system using vertical disparity information for computing the viewing parameters d and g will be susceptible to an induced effect due to a spurious g being computed when vertical magnification is introduced. Interestingly, observers do not report feeling that they are 'not looking straight ahead'

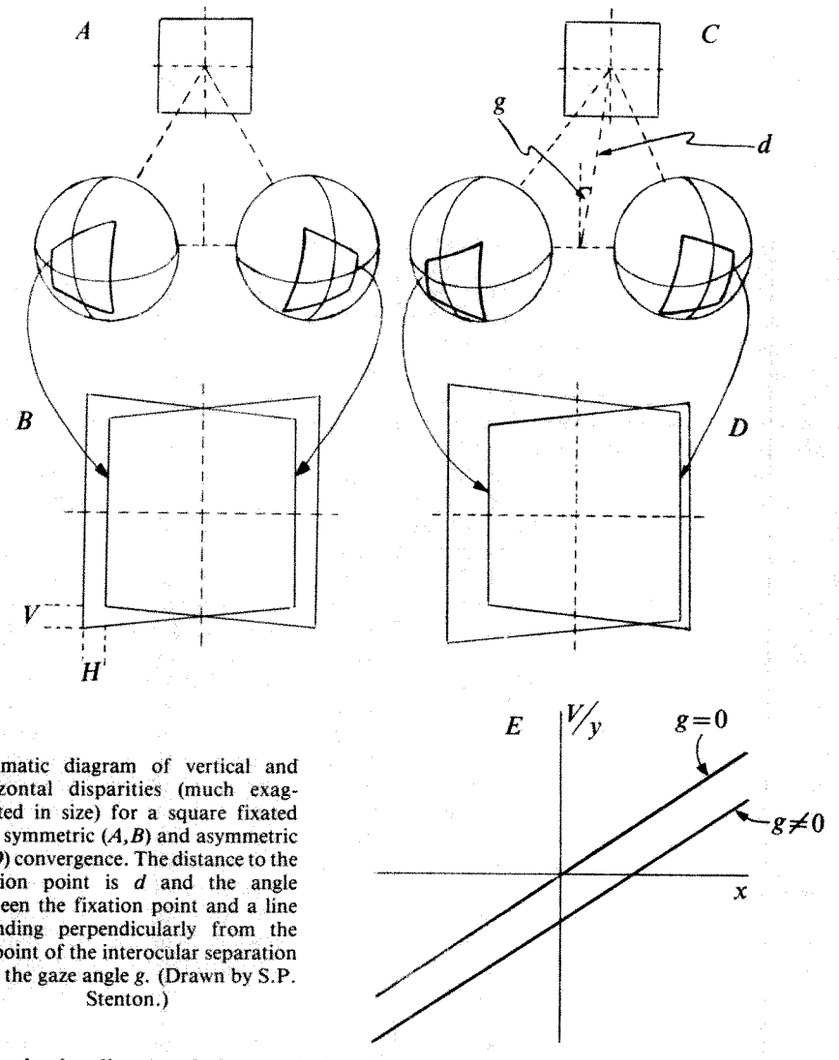
0028-0836/84/070592-02$01.00

© 1984 Macmillan Journals Ltd

when experiencing the induced effect, so if it is due to a visual computation of g it must be one that is either solely used for interpreting H values or one that is over-ruled by extra-retinal information about the positions of the eyes as far as 'felt position' is concerned.

The logic of Mayhew and Longuet-Higgin's theory of binocular vision is quite independent of the question of whether any particular visual system uses it. That is, the theory provides a method for recovering d and g from visual information alone (for near distances) which may or may not have been discovered during the evolution of biological visual systems. Nevertheless, it is of considerable interest to ask whether the human visual system uses the method and the induced effect is *prima facie* evidence that it does indeed do so. However, the 'd/g hypothesis' of the induced effect, as it has been called[8], is by no means the only explanation currently being debated (see ref. 2) and it therefore becomes necessary to enquire whether psychophysical details of the induced effect fit its predictions.

To date, psychophysical predictions drawn from the d/g hypothesis have survived attempts to falsify them as long as the requirement is met that experimental conditions present vertical size differences between images which could arise in natural viewing. Not surprisingly, this is a requirement that adherents of the hypothesis regard as reasonable. They point out, for example, that the fact that the induced effect reaches a maximum at magnifications of about 4–6 per cent is as expected because larger magnifications could only be produced by unrealistically large gaze angles.



An objection to the hypothesis can be drawn from Westheimer's report[9] that sensitivity to vertical magnifications falls well below that for horizontal ones. This appears quite at odds with a hypothesis which demands V values be measured with great precision. However, when Westheimer's experimental conditions are examined with the d/g hypothesis in mind, it becomes clear that the large d he used (3 m) means that he was presenting magnifications that would need impossibly large g values to obtain them. In such circumstances, it can be argued that an induced effect would be difficult to observe.

A crucial prediction of the hypothesis is that the size of the induced effect should be scaled by d. Gillam[10], who has independently arrived at a theory of the induced effect which is much the same as that of Mayhew and Longuet-Higgins, recently reported data that she initially though falsified this prediction. However, when she re-analysed her results excluding those conditions with d/g combinations that could not occur in natural viewing, she found that the remaining data fitted the prediction remarkably well.

One characteristic of the induced effect which Ogle[1] emphasized is that it is very much a 'whole field' phenomenon. For example, he discovered that an induced rotation can be seen for a field of vertical rods even when only one rod carries vertical disparity information (by fixing some beads to it). That is, V values in one part of the field can create a rotation of the entire field of view. This result is consistent with the d/g hypothesis because d and g are intrinsically whole-field viewing parameters: only one d and g combination can exist at any one time and so it makes obvious sense to compute a single d/g pairing and to use it for interpreting H values over the whole field of view. The same kind of interpretation can be given of results, soon to be reported in *Nature*, showing that it is the average vertical magnification that seems to determine the size of the induced effect[8]. This might reflect a sensible pooling strategy for computing whole-field values of d and g given the small size of vertical disparities.

It may be that the new theory will cause a flurry of new papers on vertical disparity processing as the d/g hypothesis and its competitors are exposed to critical psychophysical examination. If so, this will be a case of experimental interest being led by a clear theoretical exposition of the nature of a given visual computation, and not by the discovery of a new illusion whose potential computational significance is quite unclear, as has so often happened in the history of psychophysics (for example, selective adaptation effects such as the McCullough effect). Conducting psychophysics within the context of a computational theory is very much in keeping with the research framework proposed by Marr[11] and it will be interesting to see whether the outcome in this case will achieve that all too rare occurrence: a clear and definite conclusion about what some psychophysical effects really mean. □

S.P. Stenton is thanked for his help in preparing this article.

Schematic diagram of vertical and horizontal disparities (much exaggerated in size) for a square fixated with symmetric (A,B) and asymmetric (C,D) convergence. The distance to the fixation point is d and the angle between the fixation point and a line extending perpendicularly from the midpoint of the interocular separation (I) is the gaze angle g. Cell biology

Membrane traffic and the problem of protein secretion

from Miranda Robertson

THE problem of how to get hydrophilic proteins across hydrophobic membranes is fundamental to both prokaryotic and eukaryotic life; so it would not be unreasonable to expect to find the solution conserved across the evolutionary spectrum from bacterial to animal cells. In fact, however, the conservation of secretory mechanisms is a controversial issue — a state of affairs which may turn out to reflect the existence of more than one secretory mechanism. The present state of the evidence, now beginning to show signs of convergence, was one of the topics of a recent conference* which also dealt with the exclusively eukaryotic problem of what controls the continuous and complex traffic of membrane and secreted proteins through the membrane-bounded compartments of the cell.

The main point of contention is whether secretion in bacteria depends on signalling, guiding, regulating and possibly pore-forming molecules analogous to those that comprise the machinery of transit across the endoplasmic reticulum of eukaryotes[1]. It is already well established that most secreted proteins of both bacterial and animal cells are synthesized with amino-terminal leader — or 'signal' — peptides that are enzymatically cleaved from the completed molecule after transport; and that eukaryotic signals are intelligible to bacterial enzymes and vice versa: *Escherichia coli* will, for example, process and secrete insulin[2] — albeit not very efficiently. Yet according to the work of W. Wickner (UCLA) and L. Randall[3], bacteria and even liposomes can transport proteins across their membranes post-translationally and without assistance from proteins other than the leader peptidase[4,5]; while it is clear that in eukaryotes things are much more complicated.

Two components of the eukaryotic secretory mechanism have already been identified and purified. The first, the signal recognition particle (SRP), binds to the leader peptide of nascent proteins and halts translation until the ribosome has engaged with the endoplasmic reticulum (ER). The SRP is now known to consist of a 7S RNA bound to six proteins[6], the two smallest of which bind specifically to *Alu* repeats at the ends of the RNA (P. Walter *et al.*, Rockefeller University) — which incidentally suggests that, in general, the hitherto mysterious *Alu* transcripts found in the cytoplasm may all turn out to mediate important functions, and calls into question the selfishness of the DNA that encodes them.

The second identified secretory component is the docking protein on the cytoplasmic face of the ER. This protein engages with the SRP, releasing the translational block so that synthesis can proceed and the nascent polypeptide is transported co-translationally into the lumen. There is preliminary evidence that the translocation step involves at least one more protein (D. Meyer, EMBL): secreted molecules are not translocated through artificial lipid bilayers supplied only with purified SRP and docking protein. Furthermore, ER membranes inactivated by mild proteolysis can be reconstituted with a purified proteolytic fragment of the docking protein, though after more prolonged proteolysis of the membranes this is no longer possible, presumably because of the destruction of a further component of the translocation mechanism more closely associated with the membrane.

There is clear evidence that the SRP component has been highly conserved in eukaryotic evolution: it can be reconstituted from *Xenopus* or *Drosophila* 7S RNA and mammalian proteins. And now it seems possible that an analogous particle is involved in the secretion of at least some bacterial proteins. Through the analysis of temperature-sensitive mutants of *E. coli* J. Beckwith (Harvard University) and colleagues have been able to identify proteins essential for the secretion of some bacterial products. Antibodies to one of these, the Sec-A protein, precipitates a 6S RNA with some homology to the 7S eukaryotic RNA (H. Liebke, Yale University).

But if Beckwith's work on *E. coli* mutants is beginning to make bacterial secretory mechanisms look more like eukaryotic ones, G. Schatz's (Basel University) analysis of yeast mitochondrial proteins is making eurkaryotic mechanisms look more like the prokaryotic ones described by Wickner. According to Wickner, the efficient post-translational transport of the M13 coat protein by *E. coli* is independent of proteins but dependent on membrane potential[5]. The transport of proteins encoded in the eukaryotic nucleus into mitochondria, which can be regarded as an inside-out version of the same process, is also post-translational and dependent on membrane potential. Furthermore, a recent analysis of the effects of mutations introduced into the leader peptides of bacterial secreted proteins lends weight to the increasing evidence[3] that there may be not be any fundamental difference between post- and co-translational mechanisms of transport: M. Inouye (SUNY) reports that certain mutations will convert a co-translationally transported protein into a post-translationally transported one.

The mechanism of transport is not the only important issue that arises in connection with mitochondrial proteins. Unlike the membrane proteins made by a bacterial cell, those made in eukaryotes have a choice of membranes with which to become associated, and must be targeted to the right one. One obvious possibility is that the leader sequences that target proteins to the membrane are specific for different cellular membranes. Not all mitochondrial proteins however are synthesized with leader peptides; and Reizman and his colleagues in Schatz's laboratory have now been able to show that a 70,000-molecular weight protein specifically targeted to the mitochondrial outer membrane in yeast will get lost in the cytoplasm if part of its N terminus is deleted by manipulation of the cloned gene[7,8].

The great advantage of yeast for the study of eukaryotic mechanisms is that mutants are relatively easily come by; and it is yeast mutants that may in the end provide the key to one of the most important and least understood of all problems in intracellular traffic: the differential routing of different membrane proteins through the specific formation and fusion of membrane vesicles. It is clear, for example, that once a secreted protein has been successfully extruded into the ER, there is more than one possible route by which it may reach the cell surface; and mutations selectively affecting the different paths would be invaluable. This is the importance of the approach of R. Schekman and his colleagues (University of California, Berkeley) who have isolated temperature-sensitive mutants of yeast blocked at four different stages in the progress of secreted proteins from the ER to the cell surface. The general usefulness of these mutants will of course depend — once again — on how far the secretory mechanisms have been conserved. Schekman and his colleagues have already established, for example, that, as in animal cells, different secreted proteins reach the cell surface at different rates; and that glycosylation is necessary for the correct processing and secretion of some, though not all, of them[9].

The crucial question, however, is whether these differences are due to the differential interaction of the proteins with components of a common path, or whether they reflect different paths. In animal cells there is little doubt that distinct paths exist — most obviously in those cells in which the secretion of some specialized products is inducible by hormones. Distinctive properties of the inducible path are storage in granules in the absence of stimulation, and the processing of secreted prohormones to their mature form. Thus, for example, if fibroblasts, in which secretion is not normally inducible, are transfected with pro-

The virus verified

UNTIL the advent of the electron microscope, viruses were to the biologist what atoms had long been to the physicist: entities which could not be seen on account of their small size but which proved exceedingly fruitful in accounting for observed phenomena.

The earliest electron micrographs to reveal unmistakably the head-and-tail structure of viruses were of the viral strain originally called 'anti-coli PC', and now known as bacteriophage T2, taken by Thomas Anderson(RCA Research Laboratories) and Salvador Luria (Columbia University) in the week of 2 March 1942 and published the same year in *Proceedings of the National Academy of Sciences U.S.A.* (**28**, 127). Anderson recorded the phage particles at a magnification of x45,000 (below left) and their attachment to the gamma or PC strain of *Escherichia coli* bacilli at x50,000 (below right), both on Kodak Lantern slide glass plates using an RCA model B electron microscope and very highly concentrated stocks of bacteriophage.

A typical bacteriophage T2 particle possesses a head 60–80 μm in diameter and a tail 120–130 μm long and 20 μm thick. In the right-hand micrograph, the bacteriophage is seen attaching itself to the cell walls of a bacterium, living up to its name of 'bacterium eater'. With hindsight, Anderson describes the ensuing viral attack as follows: rather like a hypodermic syringe, the "attachment causes the tail sheath to contract which drives the needle [an extension of the neck below the head, invisible on the 1942 micrographs] into the bacterial wall, which somehow induces the DNA contained in the head to pass through the needle into the bacterium. There the DNA takes over the synthetic machinery of the bacterium to make some 100 daughter phage particles in 20 minutes. The bacterium then lyses to release the daughter particles into the medium where each of them can encounter a fresh bacterium to repeat the life cycle". The infecting phage particles adsorbed onto the bacterial wall remain stuck fast, their delivery complete and their role fulfilled. **Jon Darius**

insulin they will secrete the unprocessed molecule (R. Kelly, University of California, San Francisco). Conversely, AtT-20 cells, which inducibly process and secrete adrenocorticotropic hormone, can also be induced to process and secrete insulin after transfection with the proinsulin gene. Unstimulated AtT-20 cells will secrete the unprocessed hormones at low levels, presumably via the constitutive path. This is suggestive, though not strictly conclusive, evidence for two separate vesicular pathways.

And the most recent work of Schekman and his colleagues suggests that yeasts also have distinct secretory paths — although the evidence in this case concerns only constitutive secretion. Schekman and his co-workers find that isolated secretory vesicles contain all the secretory enzymes of yeast but only a subset of the plasma membrane proteins. If the membrane proteins are travelling by different routes, however, they converge at the final step: mutations affecting the last stage in secretion also prevent the appearance of any membrane protein at the cell surface.

For vesicle traffic originating at the cell surface — and particularly concerning the recycling of membrane receptors — there is some hope that human mutants may soon provide important insights. Receptor recycling has already been reviewed in *Nature*[10] and elsewhere[11,12] and it is now generally accepted that surface receptors enter the cell via clathrin-coated pits whence they may either return to the cell surface after releasing their ligand, or progress to the lysosomes for degradation.

With the discovery that some forms of familial hypercholesterolaemia are due to mutations that interfere with the biosynthesis or post-translational processing of low-density lipoprotein (LDL) receptors[11], it has become clear that defects in cholesterol uptake may make it possible to identify and understand branchpoints in intracellular vesicle pathways. J.L. Goldstein and his colleagues (University of Texas, Dallas) have, for example, identified a mutant receptor that binds cholesterol normally but fails to aggregate in coated pits; and they are now in the process of cloning LDL receptor cDNA, which will enable them to analyse such defects at the molecular level.

Mutant receptors, and mutant viruses borrowing cellular secretory paths, may help to reveal mechanisms that for the time being can only be inferred from morphological and kinetic studies. But the most powerful approach should lie with the temperature-sensitive mutants of yeast: first, because they may affect components of the selective mechanism rather than the selected molecule; and second, because their temperature sensitivity makes it possible to examine defects that would otherwise be lethal. □

Photochemistry

A quantum step towards artificial photosynthesis

from J. Barber

ACCORDING to an article by Moore and colleagues published in this issue of *Nature* (see p.630), one of the major obstacles to the development of an artificial photosynthetic system has been overcome. For many years the goal of photochemists has been to provide an artificial system that mimics the unique properties of natural photosynthetic reaction centres — particularly their striking ability to facilitate a very rapid and efficient light-induced separation of charge without a significant back-reaction. To date, it has proved difficult to make model systems which do not suffer from high back-reaction rates; now Moore and colleagues seem to have achieved success.

Several different types of reaction centre are found in photosynthetic organisms. Higher plants and algae, which use water as a source of electrons and protons to reduce carbon dioxide and which produce oxygen as a by-product, contain two different types of reaction centre, known as photosystem one and photosystem two. Photosynthetic bacteria, which do not oxidize water, but oxidize more reducing substances such as H_2S and organic acids and therefore do not produce oxygen, contain only one type of reaction centre. Despite these differences, all photosynthetic reaction centres consist of a chromophore (P), which absorbs light energy, and a closely associated electron donor (D) and acceptor (A). The organization of these three components allows the following sequence of events to occur when a photon is absorbed by the chromophore:

$$DPA \xrightarrow{h\nu} DP^*A \rightarrow DP^+A^- \rightarrow D^+PA^-$$

The D^+PA^- state is further stabilized by rapid secondary electron transfer processes. P is always a chlorophyll molecule but the chemical nature of D and A varies, with A most often being a quinone. For photosystem one and the bacterial system, D is a metalloprotein, either plastocyanin or cytochrome *c*; the nature of the primary electron donor in the photosystem two reaction centre is unknown but under certain circumstances can be the carotenoid β-carotene. Unlike photosystem one and two, functional reaction centres of photosynthetic bacteria have been isolated free of their light-harvesting proteins and subjected to detailed physical and chemical studies.

With these preparations it has been shown that P^+A^- formation occurs within 100 picoseconds of an excitation flash from an ultrafast laser. The back-reaction is 100 times slower than the forward reaction; normally the P^+A^- radical pair will be quickly converted to D^+PA^- which then has a much longer lifetime.

Moore and his co-workers have succeeded in synthesizing a very stable molecule which mimics the photochemical properties of natural reaction centres. Their molecule consists of three covalently linked entities: a chromophore (P), a donor (D) and an acceptor (A). The chromophore used is tetraarylporphyrin which has a structure and light-absorption properties comparable to those of chlorophyll. The acceptor is a quinone and the donor is a substituted β-carotene.

Because D and A are spatially separated by the porphyrin, the tripartite molecule has some remarkable properties. Flash spectroscopy shows that D^+PA^- is generated within 200 picoseconds and has a long lifetime — charge recombination occurs on a microsecond time scale. The quantum yield for its formation is also very high and, in certain conditions, can reach 25 per cent. The energy stored in the charge complex is at least 1 V; the conversion of energy is thus remarkably efficient given that only 1.8 eV is available from the absorbed photon. Surprisingly, the stabilized charge-transfer complex is generated from the singlet state of the excited porphyrin, with triplet states occurring only when the quinone is chemically reduced before illumination. In this situation, the porphyrin triplet is converted in 20 nanoseconds to a less reactive carotenoid triplet by a protective mechanism very reminiscent of a process seen in photosynthetic tissue. In nature, carotenoids not only function to quench chlorophyll triplets but also serve as light-harvesting pigments. Interestingly, Moore and colleagues have found that in their molecular triad, 10 per cent of light energy directly absorbed by the β-carotene moiety is transferred to the porphyrin.

Clearly Moore and colleagues have synthesized a very interesting molecule which, like photosynthetic reaction centres, can efficiently use the singlet energy of an excited porphyrin molecule to bring about stabilization of positive and negative charges to store chemical potential energy. Not only does the molecular triad give a convenient synthetic system for studying very fast photochemical reactions similar to those which occur in photosynthesis, but it could perhaps be exploited in a solar cell in which the molecule would catalyse further secondary reactions which generate a usable chemical or electrical fuel. □

J. Barber is Professor of Plant Physiology and Head of the AFRC Photosynthesis Research Group in the Department of Pure and Applied Biology, Imperial College, London SW7 2BB.

100 years ago

PROFESSOR Ruskin's utterances are perhaps to be taken least seriously when he is himself most serious, and probably he was never more in earnest than in his jeremiad on modern clouds, delivered at the London Institution on the 4th and 11th inst. Probably none of the readers of Nature have been terrified by the storm cloud of the nineteenth century, but should it be otherwise we hasten at once to their relief. Twenty years before the date fixed by Mr. Ruskin for the first appearance of his portentious "plague-cloud", the writer of the present article commenced a series of observations on the forms and structures of clouds, followed a few years later by such daily charts of wind and weather as could be constructed from the data, somewhat meagre, that were then accessible. As might be expected, cyclone and anticyclone were then as they are now. The dimensions and densities of the cloud layers have not altered, neither has our moral degeneracy nor the increased smoke of our manufacturing towns developed any new form of cloud. Neither (until the phenomenal sunrises and sunsets of the last three months) has Nature, in painting the clouds, employed upon her palette any fresh tints, whatever artists may have done. Further, we have not observed, nor met with any one, except Mr. Ruskin, who has observed, that the wind during the last thirteen years has adopted a "hissing" instead of a "wailing" tone.

Admiration ought ungrudgingly to be bestowed on one who has done good service as an art critic and as a contributor to English literature. The sympathy, moreover, which, denied to those who are in advance of their age, is naturally accorded to the archaic type of mind, is enhanced by the attractiveness of a personality whose idealism is as lofty as that of Mr. Ruskin. But we maintain that there is a further sentiment which contributed to the applause which Mr. Ruskin's audiences bestowed upon him. Speaking generally, "broadly and comfortably", as he would say, Mr. Ruskin is not a representative man, yet he represents a certain spirit of Philistinism (for it merits this name), which is far from being unpopular, and which shows itself in opposition to scientific culture. He is the spokesman of that mental attitude which misinterprets the province of science and affects to misunderstand the plainest utterance of the physicist. "The first business", he says, "of scientific men is to tell you things that happen, as, that if you warm water it will boil". "The second and far more important business is to tell you what you had best do under the circumstances — put the kettle on in time for tea." "But if beyond this safe and beneficial business they ever try and explain anything to you, you may be confident of one of two things — either that they know nothing (to speak of) about it, or that they have only seen one side of it, and not only have not seen, but usually have no mind to see, the other".

Palaeoclimatology

Onset of the ice age in the North Atlantic

from Brian Funnell

IN a paper published in this issue of *Nature* (see page 620), Shackleton and colleagues[1] complete a careful interdisciplinary study of sediment cores obtained in the north-east Atlantic and establish with admirable precision that ice-rafted debris first appeared there about 2.5 Myr BP, with the first major input of debris slightly later, at 2.37 Myr BP. The results make it possible to assert with confidence that the North Atlantic and its bordering continents have been subject to periodic glaciation for no less than the past two and a half million years.

Although earlier investigations[2] of deep-sea sediments had indicated ice-rafting of debris into the North Atlantic from as long ago as approximately 3 Myr, it was not until the hydraulic piston corer was added to the Deep Sea Drilling Project's range of equipment that good-quality cores, suitable for detailed analysis, could be extracted from deep enough into ocean sediments to allow a full interpretation of the time period earlier than half a million years ago.

Shackleton and colleagues investigated one of the earlier cores to be obtained with the hydraulic piston corer (Leg 81, site 552A of the Deep Sea Drilling Project, from a depth of 2,300 metres) using a combination of micropalaeontological, palaeomagnetic and stable oxygen isotope methods.

The magnitude of the oxygen isotope signal (which mainly reflects global ice volumes) and the abundance of ice-rafted debris at 2.37 Myr leave no doubt that the extent of this episode of glaciation in and around the North Atlantic is fully comparable with the most recent glacial episode, which culminated only 18,000 years ago and melted back between 11,000 and 6,000 years ago.

This new date for the onset of general Northern Hemisphere glaciation accords well with a date of 2.4 Myr proposed by workers in the Netherlands[3] for the first indication of major cooling in and around the southern margins of the North Sea. Here there is unequivocal evidence of a massive conversion of a temperate forest cover into cold heath conditions, although there is so far no evidence of actual glacierization.

The carbonate content of the deep-sea sediments[1] (which varies in inverse proportion to the ice-rafted component) shows that before 2.5 Myr BP there was no significant sea ice in the North Atlantic. The stable oxygen isotope record shows that before 2.37 Myr ice volume maxima were absolutely less extreme, although subdued fluctuations, presumably mainly due to variations in the volume of the earlier and older Antarctic polar ice cap, still continue into the more remote past.

From the carbon isotope record of the core sediments it is clear that the formation of North Atlantic deep water by winter cooling at the surface of the Norwegian–Greenland Sea was already established by 3.5 Myr ago, before the onset of glaciation. The surface water, being cold and dense, sinks to the bottom of the North Atlantic. There it gives rise to a higher ^{13}C content in bottom-living calcareous microfossils than do the 'older' Antarctic bottom waters which have had more time to gain ^{12}C from the oxidation of ^{12}C-rich organic matter falling through the water column.

Since site 552A was drilled, Leg 94 of the Deep Sea Drilling Project has explored six more sites in the North Atlantic using the hydraulic piston corer[4], with the specific intention of elucidating the history of North Atlantic waters over the last few million years. What we can look forward to now is a detailed spatial and temporal record of past climatic changes in this critical North Atlantic area which will be invaluable for a better understanding of the mechanisms that control its physical oceanography and surrounding climate. □

Neurobiology

Building acetylcholine receptors

from Charles F. Stevens

THE Kyoto group has done it again. Just three months ago, *Nature*'s report on the C Cold Spring Harbor Symposium on molecular neurobiology noted that an important advance in channel research could be achieved by the expression in cultured cells of cDNA coding for the four kinds of acetylcholine receptor (AChR) subunits (see *News and Views* **306**, 14; 1983). Numa and his colleagues at Kyoto University have now taken this prize and at the same time made an unexpected observation on the relation between receptor structure and function (see this issue of *Nature*, p.604).

Recall that channels are integral membrane proteins responsible for the electrical activity of the nervous system and that the AChR is the best studied such molecule. The AChR is a pentameric membrane protein composed of four subunits assembled with the stoichiometry $\alpha_2\beta\delta\gamma$. Binding of acetylcholine to the receptor opens the door of a water-filled cation-selective pore for about a millisecond and lets half a million ions traverse the membrane. The channel protein has been purified, partially sequenced, functionally reconstituted, the cDNA for all four subunits has been cloned and sequenced, and genomic clones for at least one of the subunits have been identified and partly sequenced. The function of single copies of the AChR has been studied with the single-channel recording method.

As the report of the molecular neurobiology symposium pointed out, one of the next steps in clarifying the relationship between molecular structure and function would be to get the cDNA expressed in an appropriate system. Once expression has been achieved, protein structure can be altered rationally and systematically by modifying the DNA, providing a powerful tool for discovering what part subunits, domains and specific amino acids play in the operation of the AChR. The Kyoto group has made a significant start on this programme and has used an interesting approach.

There are three steps to success: constructing an expression vector, finding a method for making appropriate quantities of AChR mRNA and using a system that synthesizes and assembles receptors, and inserts them into surface membrane. Numa and co-workers combined three approaches that previously had been successful in different contexts.

O'Hare *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **78**, 1527; 1981) constructed an expression vector that can be used to transfect cultured cells so that they will express a foreign protein. The Kyoto group used a version of this vector to transfect a cell line, designated COS, prepared by Gluzman (*Cell* **23**, 175; 1981) that contains as part of its genome the simian virus 40 (SV40) DNA required for replication of that virus. The vector used by the Kyoto group contains the replication origin of the SV40 DNA and is thus easily replicated by COS cells: the result is that DNA coding for the AChR subunits is amplified and a relatively large amount of mRNA is made. Cultures were separately transfected with cDNA for each of the four types of AChR subunit, and mRNA coding for each subunit was isolated from the transfected cell lines. This message was then combined and injected into frog oocytes for transla-

tion, receptor assembly and insertion into surface membrane; Barnard *et al.* (*Proc. R. Soc.* **B215**, 241; 1982) had previously used this system to make functional AChRs from message isolated from *Torpedo* electric organs (a rich source of AChR message). The advantages of having separate systems for making message and for using it are that proportions of the message for various subunits can be controlled — for example, mRNA for a given subunit can be completely omitted — and quantity of message can be varied at will.

The Kyoto group find transfected cells make AChR message that is properly processed. Furthermore, when mRNA for all four subunits is injected into oocytes in normal proportions, functional AChRs appear in the surface membrane in numbers that reflect the quantity of message injected; these receptors have apparently ordinary electrophysiological properties and bind appropriately the snake toxin used to identify AChRs. An unexpected result is that functional receptors appeared in oocytes injected with only three of the four subunits. Apparently one of the larger subunits can substitute for another to form working receptors. Although the possibility of artefact is not entirely ruled out, substitution probably can occur because the gross structure of the various subunits is quite similar — there are strong homologies between all four subunits — and at a certain functional level they are interchangeable. That the two largest subunits are interchangeable supports the pseudosymmetric channel structures that have been proposed by several authors (for references see the paper by Numa *et al.* and the symposium report).

Before this new work from the Kyoto group, the extent to which expression of this rather complicated and delicate membrane protein could be achieved was uncertain. We now know it works; next will come an exploration of altered regulation and function due to systematic and rational changes in amino acid sequence. □

Plant science

Evolution of the oaks

from Peter D. Moore

OUR knowledge of the fossil history of the oaks has recently been greatly enriched by a description of a range of fossils from an Oligocene locality near Huntsville, Texas, by C.P. Daghlian and W.L. Crepet[1]. They have found numerous leaves, fruit and a fragment of a catkin, all of which clearly belong to an oak, or possibly several oak species, and suggest that the oak underwent a rapid evolutionary radiation between the Eocene and the Oligocene.

The genus *Quercus* (the oaks) is a large one, containing somewhere in the region of 300–500 species depending upon whose system of taxonomy you follow. It is characterized within the family Fagaceae (which includes beech and sweet chestnut) by pendulous male catkins, separate female inflorescences and by a nut partially enclosed by a cupule of bracts — the characteristic acorn. Within the genus there is a high level of interspecific fertility, so hybrids are frequent, and there is a great deal of variation in such characters as leaf shape and evergreen or deciduous habit. A high level of variation is also found within many of the species, which further complicates their taxonomy.

A number of attempts have been made to subdivide the genus into subgenera, but authors are not agreed upon the way in which this should be effected. The result is that some species are placed in different subgenera by different authorities. Given such a confused and difficult taxonomic state of affairs among the modern oak, one can only express profound sympathy for palaeontologists attempting to unravel the fossil history of the genus.

The family Fagaceae was probably present in the late Cretaceous and was certainly well represented by the early Tertiary[2]. *Quercus* wood has been found in Eocene deposits in Britain[3] and leaves and fruits in the United States[4].

The new set of fossils found in Texas were not in intimate association, so it is not possible to be sure whether they do in fact belong to a single species — indeed, careful examination suggests that they possess characters indicative of not only separate species, but even separate sub-genera.

The flower structure within the catkin, with six stamens having extrorse anthers, leads the authors to propose that it belongs to a member of the sub-genus Erythrobalanus, currently found in Central and North America. The pollen grains are coarsely scabrate, which is also true of the Erythrobalanus oaks. Some leaves found near the flowers resemble those of this sub-genus too, having finely pointed vein endings.

The fossil acorn, however, has basally thickened cup scales which are more frequently associated with another sub-genus, Lepidobalanus. This is a rather heterogeneous sub-genus, containing our two British oaks *(Q. robur* and *Q. petraea)*, some other European species (such as *Q. ilex)* and some North American species (for example *Q. alba* and *Q. arizonica)*.

The outcome of these findings is that the authors propose three new oak species, assigning the catkin to *Q. oligocenensis*, the leaves to *Q. catahoulaensis* (both sub-genus Erythrobalanus) and the acorn to *Q. huntsvillensis* (sub-genus Lepidobalanus).

The fact that this mixture of characters should be present in the same sediments, whether or not they are derived from just a single species or several, suggests that *Quercus,* by the Oligocene, had undergone a considerable degree of evolutionary development and had acquired some of the features now characterizing its present-day sub-genera. Before one can accept this rapid evolutionary radiation in oak, however, one must examine the reliability of characters used in defining sub-genera. The subdivision of the genus *Quercus* adopted by *Flora Europaea*, for example, differs considerably from that accepted by Daghlian and Crepet. Lepidobalanus is not used there, but some of its members (for example, *Q.robur*) are taken into sub-genus *Quercus* and others (for example *Q. ilex*) to a further sub-genus Sclerophyllodrys. Evidently the sub-generic boundaries within the genus are far from clear.

Pollen morphology in *Quercus* has been studied fairly intensively, but the criteria upon which any subdivision of the genus can be firmly based are a matter of dispute. Spoel-Walvins[5], for example, proposed that some of the south European oak species can be separated by pollen form and sculpturing, but the use of such characteristics in the analysis of Quaternary sub-fossil pollen in Spain has met with very limited success[6]. Examination of type material from numerous sources reveals a very wide degree of intraspecific variations in pollen sculpturing.

One must be cautious, therefore, before fully accepting the rapid evolution of *Quercus* between the Eocene and the Oligocene. The proposal does, on the other hand, tie in well with what is known of environmental conditions in that period. It was a time of climatic cooling, though probably not such a rapid cooling as was once thought[7], and of falling sea levels that left new tracts of land exposed and created new ecological opportunities. Daghlian and Crepet feel that this environmental instability could underlie the diversification of the genus *Quercus* in the early Tertiary. The next step must be the extraction and analysis of more oak fossils from Eocene and Oligocene rocks in order to examine the extent of this diversification. □

Acidic deposition and internal proton sources in acidification of soils and waters

N. van Breemen*, C. T. Driscoll† & J. Mulder*

* Department of Soil Science and Geology, Agricultural University, 6700 AA, Wageningen, The Netherlands
† Department of Civil Engineering, Syracuse University, Syracuse, New York 13210, USA

Enough is now known of the sources of hydrogen ions (protons) in natural ecosystems for the relative importance of external and internal sources to be compared. In acidic soils in the northeastern United States and western Europe, external often exceeds internal proton loading, resulting in soil acidification by aluminium dissolution and sulphate retention. One consequence is the export of ecologically significant quantities of hydrogen ion and aluminium in drainage water.

THERE is considerable controversy over the environmental impact of 'acid rain'. Some researchers claim that atmospheric inputs of anthropogenically-derived acidic substances cause acidification of soils and surface waters with serious effects on vegetation and fish[1,2]. Others contend that internal proton production in soils, sometimes intensified by changes in land use, overshadow the effects of acidic atmospheric deposition[3,4]. Thus an evaluation of the relative contributions of atmospheric inputs and internal proton sources to acidification of soil and water would be very useful. We have recently proposed an approach to identify and quantify proton fluxes and soil acidification[5,6]; we now use this approach to evaluate proton transformations for several ecosystems and discuss the implications for soil acidification and water quality.

Concepts

When evaluating acidification processes it is essential to distinguish between intensity factors (such as *p*H) and capacity factors (such as acid- and base-neutralizing capacity). Failure to make this distinction[4] lies at the root of much confusion about the nature of soil and water acidification. In aqueous systems the acid-neutralizing capacity (ANC (aq)) is determined by strong acid titration to a reference *p*H of about 4.5 and is defined as the aqueous base equivalence minus the strong acid equivalence[7].

$$\mathrm{ANC\ (aq;\ ref.\ 4.5)} = [\mathrm{HCO_3^-}] + 2[\mathrm{CO_3^{=}}] + [\mathrm{A^-}] + [\mathrm{OH^-}] - [\mathrm{H^+}]$$

where $[A^-]$ is the molar concentration of a potential proton accepting anion (such as a natural organic anion).

In an analogous manner we define the acid-neutralizing capacity of the inorganic fraction of a mineral soil as the sum of basic components minus the strongly acidic components [brackets denote molar concentrations].

$$\mathrm{ANC\ (s)} = 6[\mathrm{Al_2O_3}] + 6[\mathrm{Fe_2O_3}] + 2[\mathrm{FeO}] + 4[\mathrm{MnO_2}] + 2[\mathrm{MnO}] + 2[\mathrm{CaO}] + 2[\mathrm{MgO}] + 2[\mathrm{Na_2O}] + 2[\mathrm{K_2O}] - 2[\mathrm{SO_3}] - 2[\mathrm{P_2O_5}] - [\mathrm{HCl}]$$

Weak acid components (such as CO_2 (s), SiO_2 (s) and H_2S (s)) do not contribute to ANC (s) because of their inability to accept or donate protons at reference *p*H values of soils (generally *p*H 2–5)[5]. Also because the nitrogen content of mineral material is generally low, nitrogen components are not included in our definition of ANC (s).

The capacity factor ANC, rather than the intensity factor *p*H, is directly influenced by addition or depletion of protons, and hence is fundamental to acidification and alkalinization. *p*H generally, but not always, decreases during addition of protons and generally, but not always, increases during depletion of protons[5]. While *p*H is of more direct ecological importance than ANC, the relationship between *p*H and ANC is beyond the scope of this paper. Detailed discussions on the functional relationship between *p*H and ANC (aq)[7] or soil mineralogy[8] (which in turn determines ANC (s)) are available elsewhere.

Soil acidification is defined as a decrease in ANC (s) and is accomplished by removal of cationic components (such as CaO) from a mineral soil or, to a lesser extent, by addition of acidic components (such as SO_3). Conversely soil alkalinization is an

Table 1 Proton producing and consuming processes in terrestrial and aquatic ecosystems

Proton-producing processes		Proton-consuming processes
(1) Atmospheric input	H^+ (aq(rain/drain water)) $\rightleftharpoons$ H^+ (aq(soil solution))	(1) Drainage
(2) Assimilation of cations	M^{n+} (aq) + nR−OH (org) $\rightleftharpoons$ (R−O)$_n$M (org) + nH$^+$ (aq)	(2) Mineralization of cations
(3) Mineralization of anions	nH$_2$O + R$_n$−A (org) $\rightleftharpoons$ nR−OH + A^{n-} (aq) + nH$^+$ (aq)	(3) Assimilation of anions
(4) Dissociation of acids	H$_n$A (aq) $\rightleftharpoons$ A^{n-} (aq) + nH$^+$ (aq)	(4) Protonation of anions
(5) Oxidations	Red (aq, s, g) + mO$_2$ + nH$_2$O $\rightleftharpoons$ Ox^{r-} (aq, s, g) + rH$^+$ (aq)	(5) Reductions
(6) Reverse weathering of cations	M^{n+} (aq) + $\frac{1}{2}n$H$_2$O $\rightleftharpoons$ $\frac{1}{2}n$M$_{2/n}$O (s) + nH$^+$ (aq)	(6) Weathering of metal oxide components
(7) Weathering of anionic components	NO$_{(m+n)}$ (s) + mH$_2$O $\rightleftharpoons$ NO$_{(2m+n)}^{2m-}$ (aq) + 2mH$^+$ (aq)	(7) Reverse weathering of anions

Quantitatively important cations (M^{n+}) include Ca^{2+}, Mg^{2+}, Na^+, K^+ (equations (2), (6)), NH_4^+ (2) and Al^{3+} (6). Important anions (A^{n-}) are $H_2PO_4^-$ (equations (3, 7)), NO_3^- (3) and SO_4^{2-} (3, 7). Mineralization and assimilation of SO_4^{2-} and NO_3^- involves oxidation and reduction processes but the net reactions are equivalent to equations (3). Important reduction (Red)–oxidation (Ox) couples in gas/water/soil systems include NH_4^+/NO_3^-, N_2/NO_3^-, H_2S/SO_4^{2-}, SO_2/FO_4^{2-} and Fe^{2+}/Fe_2O_3. Reduction/oxidation reactions (5) have been coupled to the O_2—H_2O system. In actuality, organic matter (CH_2O) is usually the electron donor in reduction reactions (5); CH_2O oxidation is implicitly expressed in this reaction because organic matter is oxidized during aerobic respiration ($O_2 + CH_2O \rightleftharpoons H_2O + CO_2$). Cation and anion exchange reactions can be represented by reactions (6) and (7).

* Proton neutralization due to protonation of HCO_3^-.

† Organic acid deprotonation rather than CO_2 deprotonation (measured).

‡ Organic acid deprotonation rather than CO_2 deprotonation (estimated by discrepancy in charge balance of drainage water).

§ Largely sulphate reduction.

‖ Proton neutralization due to sulphate reduction is not included in ΔANC (s).

¶ Anion input, output and assimilation data from L. A. Bruynzeel (personal communication). The assumptions are: sulphur input equals sulphur output; HCO_3^- in drainage water estimated from charge balance discrepancy.

High rates of net Na^+, K^+ and Mg^{2+} mineralization in a young (recently cut, <40 yr) forest plantation.

** Input of Cl^- and output of SO_4^{2-} are estimated from discrepancy in charge balance. Data from weir are used as output. Cl^- output is assumed to equal Cl^- input.

†† Dry deposition of S was assumed to be SO_4^{2-} in throughfall less SO_4^{2-} in precipitation.

‡‡ Assumed to be due to pyrite (FeS_2) oxidation.

§§ The transformation of H_2S_2 (s) to SO_3 (aq) that is removed by leaching does not change ANC (s), so ΔANC (s) is equivalent to H^+ consumed in weathering.

‖‖ Wet deposition was estimated from Cl^- output in the unvegetated lysimeter, assuming that Cl^- input equalled Cl^- output and the stoichiometry of ions in precipitation in 1952–55 were similar to values in 1980 [14]. Sea spray on vegetation surfaces was calculated by assuming that Cl^- output less Cl^- input equals Cl^- dry deposition. Any SO_4^{2-} output that exceeded SO_4^{2-} inputs from wet deposition and sea spray was attributed to dry deposition of SO_2.

¶¶ Biomass accretion was estimated by measured increases in tree height and literature values of nutrient content [15,16].

Mineralization of organic N.

increase in ANC (s). Changes in ANC (s) may involve both the weathering/formation of soil minerals, and adsorption/desorption reactions. Although Fe_2O_3 and Al_2O_3 are included in ANC (s), they are relatively insoluble at *p*H values above 3 and 5 respectively and therefore are important only in the acidification of moderately to strongly acidic soils. Oxidation of FeO to Fe_2O_3, common in weathering zones with FeO-containing minerals, increases ANC (s). Because this increase is difficult to quantify and is of no practical significance we will neglect the effect of Fe_2O_3 on ANC(s).

Soil acidification occurs by an irreversible flux of protons to the soil. Proton sources include: (1) atmospheric inputs of acidic or potentially acidic substances (such as SO_2); (2) net assimilation of cations by vegetation; (3) net mineralization of anions from organic matter; (4) deprotonation of weak acids; (5) oxidation reactions; (6) precipitation (reverse weathering) of cations; and (7) mineral weathering of anionic components (Table 1).

Protons entering or produced in the soil may be removed by (1) export in drainage water, (2) net mineralization of cations in organic matter, (3) net assimilation of anions by vegetation, (4) protonation of anions, (5) reduction reactions, (6) weathering of cationic components and (7) precipitation of anions (Table 1).

Free or bound protons (such as H_2CO_3) are transferred to the soil predominantly through the dissolution of cationic components.

If a soil completely neutralizes proton inputs, basic cations

(Ca^{2+}, Mg^{2+}, Na^+, K^+) are released and exported from the soil by vegetation uptake or by outflow of drainage water, resulting in soil acidification. Aqueous alkalinization (an increase in ANC (aq)) generally occurs as a counter-process to soil acidification. Alkalinization of the percolating soil solution is accomplished by neutralization of free protons in solution by soil, or by the donation of bound protons to the soil resulting in the formation of unprotonated anions (such as HCO_3^-).

If there are considerable proton inputs to a soil, and soil-bound basic cations are present in low concentrations or have characteristically slow dissolution kinetics, or the retention time of water within the mineral soil is short, the neutralization of proton inputs may be incomplete and result in the export of free protons in drainage water from the soil. A consequence of elevated concentrations of free protons (low *p*H) is the dissolution of aluminium from soil. Aluminium dissolution is realized in acidic conditions ($pH < 5.5$) and results in a solution that contains both hydrogen ion and aluminium base neutralizing capacity[9]:

$$\text{BNC (aq, ref. } p\text{H } 5.5) = H^+ + n[Al^{n+}].$$

Elevated levels of dissolved aluminium are ecologically significant due to toxicity to aquatic organisms[10,11] and vegetation[12].

There are two approaches to the quantification of soil acidification. A historic approach requires the determination of ANC (s) in a complete soil profile, including parent material, or a chronosequence of soils. An actualistic approach involves the measurement of all proton fluxes so that a proton budget can be calculated. The measurements required to compile a proton budget include: the flux of solutes entering and leaving the ecosystem; the net assimilation (or mineralization) of substances by living or dead biomass; the net quantities of potentially acidic gases and aerosols entering and leaving the ecosystem; and the net sorption (for example, by precipitation) or desorption of substances in the soil. The advantages of the proton budget approach over the historic approach are obvious; it reflects the current conditions of an ecosystem, identifies various processes involved in soil acidification, is sensitive compared with the analysis of soil material and requires no assumptions about the authenticity of soil parent material. In our discussion of soil acidification we will follow only the proton budget approach. Further details on the processes of soil acidification and methods of quantifying soil acidification are available elsewhere[5].

Proton accounting

We have developed proton budgets using data from several ecosystem studies (Table 2). To facilitate our discussion we have categorized total proton sources and sinks, for each ecosystem into their principal constituents. Proton sources include: (1) atmospheric inputs of free protons and SO_2; (2) the proton loading associated with nitrogen transformations, which is the net ammonium input plus the net nitrate output (this accounts for the protons generated during the net assimilation of atmospheric NH_4^+ by biota and net nitrification); (3) the deprotonation of CO_2 or organic acids; (4) net assimilation of non-nitrogen cations by biomass (or net non-nitrogen anion mineralization); and (5) anion weathering (plus any reverse cation weathering).

We have subdivided proton sinks into: (1) cationic weathering (plus any reverse anionic weathering); (2) biomass assimilation of non-nitrogen anions; (3) proton neutralization associated with nitrogen transformations (which is net nitrate input/net ammonium output); and (4) drainage export of free protons.

We define external proton inputs (which we presume are largely anthrophogenic in origin) as atmospheric inputs of H^+ and SO_2 plus proton sources minus proton sinks due to N transformations or, in other words, net ammonium input minus net nitrate input. The balance of proton sources (3), (4) and (5) will be considered as internal proton loading. It is invariably arbitrary to partition proton loading into internal and external sources. For example, atmospheric NH_4^+ is generally derived from NH_3 volatilization and protonation by acidic atmospheric substances (for example, H_2SO_4 from SO_2, HNO_3). Therefore protons generated from assimilation or oxidation of atmospheric NH_4^+ in the soil clearly reflect an external source. On the other hand in degrading ecosystems mineralization of organic nitrogen followed by nitrification will result in net internal generation of protons. However, nearly all ecosystems considered here increase in biomass or are at steady state, with net ammonium inputs generally exceeding net nitrate outputs. Therefore exported nitrate can be generally assumed to come from atmospheric NH_4^+, so that the proton loading from nitrogen transformations is considered here as an external source. Note that atmospheric N_2 fixation involves no proton transfer. Only after mineralization of organic N to NH_4^+ or NO_3^- will fixed N_2 become involved in proton transfer. This process is accounted for by an input–output budget of NO_3^- and NH_4^+.

To assess the relative importance of external proton inputs to the total sources of an ecosystem, we define the external–internal proton ratio (EIPR) as the ratio of atmospheric inputs of mineral and potentially mineral acids to the internal proton loading.

The rate of soil acidification is equivalent to the proton flux associated with anionic weathering minus the proton flux associated with cationic weathering. The summed proton sources and sinks should, theoretically, be equal. A comparison of the total proton sources and sinks provides an estimate of the accuracy of the budget. Budget discrepancies may be due to errors in measurements or to proton transfer processes that have been overlooked.

To illustrate the nature of soil acidification and its role in regulating drainage water quality, we have also tabulated the constituents contributing to ΔANC (s), ΔANC (aq) and the transport of BNC from the ecosystem (Table 3). The contributions to ΔANC (s) have been subdivided into changes in basic cation components (CaO, MgO, Na_2O, K_2O), aluminium components (Al_2O_3) and anionic components (SO_3, P_2O_5, HCl). Because most soils considered here are oxidized and without extremely low *p*H values, soil acidification due to changes in iron and manganese component content is generally insignificant. Changes in ANC (aq) have been attributed to changes in free proton, bicarbonate, and organic anion concentration. Because of the ecological significance of aqueous acidity, we have also tabulated the quantities of dissolved hydrogen ion and aluminium exported from soils as well as the *p*H of the drainage water.

Soil acidification and proton sinks

There is considerable variation in the extent and nature of proton fluxes in ecosystems (Table 2). Data from the global terrestrial ecosystem (case 1) and sites where precipitation inputs exceed evapotranspiration indicate that soils generally undergo acidification (ΔANC is negative), while water percolating through the soil increases in ANC (aq). However, in arid or semi-arid regions, like Lake Chad (case 2), the supply of solutes exceeds leaching of solutes and reverse weathering occurs (such as $CaCO_3$, or smectite formation), resulting in soil alkalinization.

Although most soils acidify, the extent to which this process occurs is highly variable and essentially depends on soil type, geology and the quantity of drainage water. We have subdivided ecosystems into those with: (1) low rates of soil acidification (<2.5 kmol hectare^{-1} yr^{-1}); (2) intermediate rates of soil acidification (2.5–7.5 kmol hectare^{-1} yr^{-1}) and; (3) high rates of soil acidification (>7.5 kmol hectare^{-1} yr^{-1}).

Ecosystems with low rates of soil acidification often have acidic podzolic soils which are derived from granitic or base poor materials (cases 5–8), strongly weathered volcanic materials (case 9) or are bogs (cases 3, 4). Ecosystems with intermediate rates of soil acidification generally have acidic soils containing appreciable amounts of weatherable silicate minerals. Examples include soils that are derived from young volcanic materials (case 15), decalcified fluvial deposits (cases 12–14) and decalcified loess (cases 10 and 11). Soils with high rates of

Table 3 Constituents contributing to the rate of soil acidification (ΔANC (s)) and to the change in acid neutralizing capacity of water percolating through the soil (ΔANC (aq)) and the transport of BNC (aq) in drainage water

* For most sites the chemical speciation of Al is unknown, so it was assumed to be trivalent. As a result the contribution of Al (in kmol $\frac{1}{3}$ Al^{3+}) to BNC is an upper limit.

† Except Antarctica, data from ref. 34.

‡ River input 2,020 mm yr^{-1}, evaporation 2,100 mm yr^{-1}.

§ Net annual storage of water in the bog was 190 mm.

‖ High percolation rate associated with a depletion of soil moisture.

¶ Runoff is greater than precipitation inputs due to glacial melting.

acidification are generally calcareous (cases 17–20). An apparent exception to these subdivisions is the Northern Cascades (case 16). Here soils are thin and derived mainly from schists and quartzdiorite, but rates of soil acidification are extremely high (−9.9 kmol hectare^{-1} yr^{-1}). This apparent anomaly may be attributed to glacial activity and the very large amount of water draining the region.

In well drained soils, weathering of cationic components is the principal mechanism of proton neutralization (Table 2). However, bogs (cases 3, 4) are generally rich in organic matter and weathering of minerals is quantitatively unimportant. In the reduced environment of bogs proton removal is predominantly achieved through biomass assimilation of anions (S, N, P), reduction of atmospherically derived sulphate and nitrate, and export of free protons.

Internal proton sources

In ecosystems with relatively high rates of soil acidification, the deprotonation of carbon dioxide is generally the most significant proton source (Table 2; cases 16, 18, 19, 20). This transfer of protons is greatly enhanced when the *p*H values of soil solutions approach or exceed the proton dissociation constant of CO_2 ($pH > pK_a = 6.3$). Dissolved organic acids can deprotonate at low *p*H ($pK = 4$–5) values as is apparent in the two bogs (cases 3 and 4) and two of the four podzols (cases 5 and 8) considered here. Note that transport of organic anions (A^- in Table 3) causes soil acidification only when cations are removed simultaneously with A^- in the drainage water. Transport of partly dissociated organic acids ($HA + A^- + H^+$) may cause relatively low *p*H values in the drainage water but has, in fact, no effect on either ANC (s) or ANC (aq). Contrary to the contention of others[3,4], organic matter in the soil has no direct role in soil acidification, but merely acts as a (cation) exchanger. Effects of cation exchange on the proton budgets are accounted for under the category 'weathering'.

In terrestrial systems with acidic soils and low to intermediate rates of soil acidification, biologically mediated processes can contribute significantly to the internal production of protons. Most vegetation assimilates an excess of non-nitrogen cations over anions. In an aggrading ecosystem this process results in a net production of protons (cases 6–8, 10–14). In a few ecosystems (cases 9 and 21) biomass serves as a net proton sink due to net mineralization processes.

In a deforested watershed at the Hubbard Brook Experimental Forest (HBEF) in New Hampshire (case 21) a herbicide was applied for 3 yr to prevent vegetation regrowth in the deforested area while decomposition processes were allowed to proceed. Decomposition of the forest floor followed by nitrification resulted in excessive proton production. Levels of proton flux, largely resulting from these nitrogen transformations even exceeded some of our values for calcareous systems. Note that only a modest fraction (31%) of this proton loading was neutralized by weathering reactions while the balance of these protons was neutralized through net cationic decomposition of the forest floor and nitrate loss (denitrification?). In ambient conditions at the HBEF (case 7) proton neutralization is largely (88%) achieved by cationic weathering. While the deforestation experiment is an extreme example, it illustrates the nature of mineralization processes in proton transformations.

Biomass also indirectly regulates proton flux by reducing the flow of water through soil. Using data from Castricum, a cal-

careous site in the Netherlands, we computed proton budgets for sites under pine (*Pinus nigra*; case 20), oak (*Quercus robur*; case 19) and with no vegetation (case 18). Although the soils and geology at all three sites are similar, proton flux and rates of soil acidification were very different. Solute concentrations in drainage water were highest at the pine site, intermediate at the oak site and lowest at the unvegetated site. However, these trends in solute concentration were more than compensated for by variations in water flux. High rates of transpiration from the pine stand reduced the flow of water and solutes percolating through the soil and therefore reduced the rate of soil acidification. Drainage fluxes were intermediate at the oak stand and highest at the unvegetated site; the rates of soil acidification at these sites varied accordingly.

External proton sources

As the world average (case 1) and data from more or less pristine ecosystems (cases 2, 9, 15, 16) would attest, atmospheric inputs do not contribute significantly to the proton loading of these ecosystems. However, near centres of anthropogenic activity such as the northeastern portion of the USA (cases 3, 7) and in northwestern Europe (cases 4–6, 8, 10–14, 17–20), atmospheric proton inputs are substantial. For ecosystems with low to intermediate rates of soil acidification, external loading can be a major fraction of the total proton sources. In the USA (cases 3, 7) atmospheric proton inputs largely occur as free protons and to a lesser extent as SO_2. In Central Europe dry deposition is a very significant mechanism of proton loading. At Hackfort (cases 12–14, 17) in the Netherlands transformations of atmospherically derived ammonium ($(NH_4)_2SO_4$), mainly from dry deposition, account for 53–66% of the total proton sources[13]. At Solling in West Germany (case 10, 11), the rates of soil acidification are much greater in a spruce site (-5.9 kmol hectare^{-1} yr^{-1}) than in a beech site (-2.9 kmol hectare^{-1} yr^{-1}). Spruce is more efficient than beech in scavenging sulphur from the atmosphere[11] (inputs due to dry deposition are 2.8 kmol hectare^{-1} yr^{-1} in spruce compared with 0.9 kmol hectare^{-1} yr^{-1} in beech) resulting in higher rates of soil acidification at the coniferous site.

Information on the input of external protons is insufficient to assess ecosystem sensitivity to acid inputs. Rather, a good measure of the capability of an ecosystem to withstand ambient external proton loading is the external/internal proton ratio (EIPR). For example, Castricum (cases 18–20) receives high atmospheric loadings of protons (2.2–2.5 kmol hectare^{-1} yr^{-1}), but this external input is small relative to the internal proton sources in the calcareous soils (EIPR = 0.13–0.26). Such soils can easily accomodate this external proton load because soil acidification proceeds entirely through the dissolution of basic cations, mainly Ca^{2+} from $CaCO_3$ (Table 3).

Systems with low rates of soil acidification such as in Birkeness, Norway (case 5), Lünebürger Heide, West Germany (case 6), the HBEF (case 7), and Gårdsjön, Sweden (case 8) are extremely proton sensitive. These systems receive inputs of acidic and potentially acidic substances (1.1–1.7 kmol hectare^{-1} yr^{-1}) that are comparable to internal proton sources (EIPR = 0.5–2.4). In these conditions soil acidification proceeds partly through the dissolution of aluminium minerals and significant levels of free protons and aluminium are present in the soil solutions and drainage waters.

In forests in central Europe (cases 10–14, 17, 19 and 20) external proton inputs are extremely high (2.2–6.3 kmol hectare^{-1} yr^{-1}) as are EIPR values for ecosystems with low to intermediate rates of soil weathering (cases 10–14). Moreover, in these ecosystems the soil acidification process is characterized by aluminium dissolution as well as strong retention of sulphate. Appreciable quantities of hydrogen ion and aluminium are exported from the soil to the drainage water.

Note that because of very low rates of internal proton production, Thoreau's Bog (case 3) and Storgama (case 4) have high EIPR values. However, these systems may accommodate high loadings of atmospheric protons through anion assimilation by biomass or by microbially-mediated sulphate and nitrate reduction.

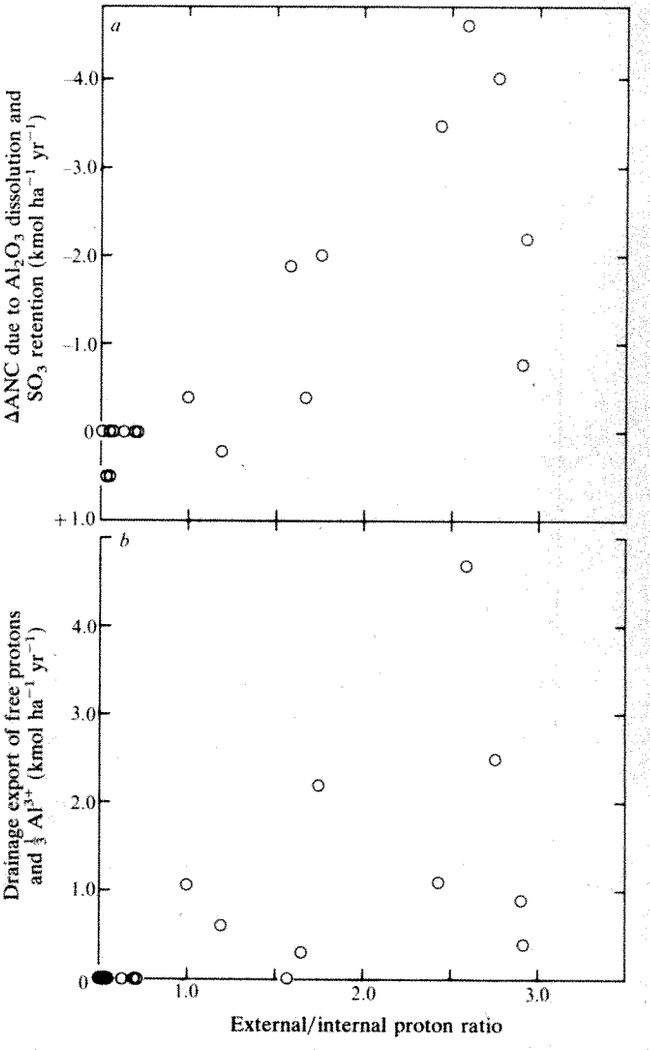

Fig. 1 The rate of soil acidification due to Al_2O_3 dissolution and SO_3 retention (*a*) and the drainage flux of BNC from the soil (*b*) as a function of the external/internal proton ratio of ecosystems. Data from bogs and deforested ecosystems are not included.

To assess the capacity of terrestrial ecosystems to assimilate ambient external acid inputs in an innocuous manner, we have plotted the rate of soil acidification due to Al_2O_3 dissolution and sulphate retention (Fig. 1*a*) and drainage flux of BNC (Fig. 1*b*) as a function of the EIPR. At low (<0.3) EIPR values ecosystems are able to assimilate proton inputs and soil acidification proceeds largely through the dissolution of basic cations. Most ecosystems with EIPR values above 0.5 show significant dissolution of soil aluminium and sulphate retention, resulting in export of free protons and aluminium in drainage waters.

Conclusions

In well drained soils in areas with excess precipitation over evapotranspiration, protons are generated by natural processes (mainly weak acid deprotonation and net assimilation of cations by the vegetation). Soil acidification results from removal of cations and retention of anions. In near-neutral soils rich in weatherable minerals, soil acidification is relatively rapid (7.5–16 kmol hectare^{-1} yr^{-1}) and mainly associated with CO_2 deprotonation. In acidic soils, soil acidification is slower (<2.5 kmol hectare^{-1} yr^{-1}) with cation assimilation and organic acid deprotonation as the principal internal H^+ sources. In the northeastern USA and central and northwestern Europe atmospheric deposition of anthropogenically-derived acidic substances (mainly H^+, SO_2 and NH_4^+) may be 1–5 kmol hectare^{-1} yr^{-1}.

This deposition exceeds internally generated protons in soils with low rates of soil acidification and in many soils with intermediate rates of soil acidification. As a result potentially toxic inorganic aluminium is released into the soil solution and H^+- and aluminium base-neutralizing capacity is transported to drainage waters.

We acknowledge the help of 24 students in calculating H^+ budgets for soil–vegetation systems. This study was funded in part by the EEC environmental programme, EUR contract ENV 650-NL, and the NSF (DEB 82-06980). Partial support for C.T.D. was provided by the Agriculture University, Wageningen.

The cloned cDNAs encoding the four subunits of the Torpedo californica *acetylcholine receptor, each carried by a simian virus 40 vector, direct the synthesis of the functional receptor in a combined expression system consisting of COS monkey cells and* Xenopus *oocytes. Our results suggest that all four subunits are required to elicit a normal nicotinic response to acetylcholine, whereas only the α-subunit is indispensable for α-bungarotoxin binding activity.*

THE nicotinic acetylcholine receptor (AChR) is a postsynaptic membrane protein complex that alters the ionic permeability of the membrane as a consequence of binding acetylcholine. The AChR from the electric organ of the ray *Torpedo californica* is composed of five subunits present in a molar stoichiometry of $\alpha_2\beta\gamma\delta$ and contains both the binding site for the neurotransmitter and the ionic channel (reviewed in refs 1–3). Recently, the primary structures of all four subunits of the *T. californica* AChR[4–6] and the α-subunit of the calf and human muscle AChR[7] have been elucidated in our laboratory by cloning and sequencing cDNAs or genomic DNA encoding these polypeptides; cDNA sequences for the γ-subunit of the *T. californica* AChR[8] and the α-subunit of the *Torpedo marmorata* AChR[9,10] have also been reported by other groups. On the basis of the amino acid sequences of the four subunits, the locations of functionally and immunologically important regions of the AChR molecule have been proposed. These include the acetylcholine binding site[4–7], the transmembrane segments[4–8,10] presumably involved in the ionic channel, and the 'main immunogenic region'[4,6,7] related causally to myasthenia gravis (reviewed in ref. 11).

One approach to verifying these proposed sites would be to introduce amino acid alterations into the respective regions of the AChR molecule and to analyse the resultant effects on the receptor function and the antigenic determinants. As a first step towards this goal, we have now developed a combined system consisting of COS monkey cells and *Xenopus* oocytes in which the synthesis of the functional AChR is directed by the cloned cDNAs encoding the four subunits of the *T. californica* receptor, each carried by a simian virus 40 (SV40) vector. This expression system has allowed us to study the effect of deletion of each subunit on AChR function.

Construction of vectors

The expression vector used (pKCRH2), a derivative of the plasmid pKCR constructed by O'Hare *et al.*[12], contained the SV40 early gene promoter, donor and acceptor splice sites derived from the rabbit β-globin gene, and polyadenylation sites derived from the rabbit β-globin gene and the SV40 early gene. The entire protein-coding sequence of the cDNA for each subunit of the *T. californica* AChR[4–6], cloned into the Okayama–Berg vector[13], was excised by cleavage at the *Hin*dIII or *Eco*RI site, which was introduced into both the 5′- and 3′-noncoding regions of each cDNA by using synthetic linkers (Fig. 1*a*). The excised cDNA fragment was inserted into the vector pKCRH2 at the *Hin*dIII site and/or the *Eco*RI site located between the acceptor splice site and the polyadenylation site derived from the rabbit β-globin gene. The structure of the

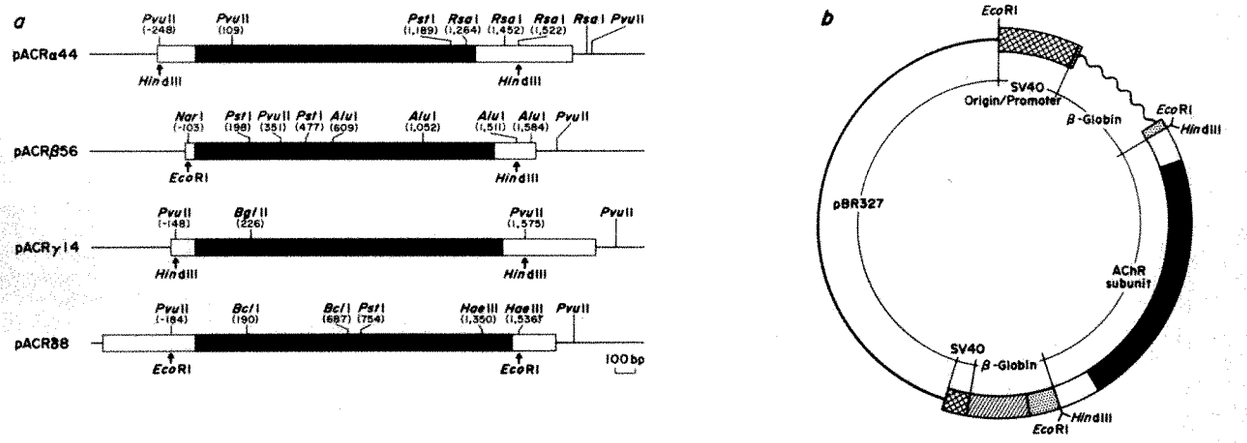

Fig. 1 Recombinant plasmids used for the expression of AChR. ***a***, Restriction maps of the cloned AChR subunit cDNAs. The plasmids pACRα44, pACRβ56, pACRγ14 and pACRδ8, carrying cDNAs for the α-, β-, γ- and δ-subunits of the *T. californica* AChR, respectively, have been described previously[4–6]. The protein-coding regions are indicated by closed boxes, the 5′- and 3′-noncoding regions by open boxes, and the vector sequence including the tails by lines. Only the relevant restriction endonuclease sites are shown and identified by numbers indicating the 5′-terminal nucleotide generated by cleavage; for numbering of the nucleotide residues, see refs 4–6. The *Hin*dIII and *Eco*RI sites introduced by the use of synthetic linkers are shown by arrows beneath the noncoding regions. ***b***, Schematic representation of pKCRH2 recombinant plasmids containing the respective AChR subunit cDNAs (pKCRα2, pKCRβ2, pKCRγ2 and pKCRδ2). The origin of the segments is shown on the inner circle. The protein-coding region of the AChR subunit cDNA is indicated by a closed box, and its 5′- and 3′-noncoding regions by open boxes. The SV40 sequences are shown by cross-hatched boxes; the orientation of the early gene promoter is such that transcription occurs clockwise. The exonic sequences of the rabbit β-globin gene are indicated by stippled boxes, its intronic sequence by a wavy line, and its 3′-flanking sequence by a hatched box. The sequence of the plasmid pBR327 is represented by a line. Only the relevant restriction endonuclease sites are shown.

Methods: The plasmid pKCRH2 was constructed as follows. The plasmid pKCR327 (given by C. Weissmann), in which the pBR322 sequence of pKCR (ref. 12) was replaced by the corresponding sequence of pBR327 (ref. 31), was partially digested with *Eco*RI, treated successively by alkaline phosphatase and by T4 DNA polymerase with the four deoxyribonucleotide triphosphates (dNTPs), ligated to the *Hin*dIII linker dCAAGCTTG, cleaved with *Hin*dIII and ligated. One of the resulting plasmids, harbouring the *Hin*dIII site in the rabbit β-globin gene sequence, was designated pKCRH2. The pKCRH2 recombinants containing the respective AChR subunit cDNAs were constructed as follows. pACRα44 was partially digested with *Pvu*II, ligated to the *Hin*dIII linker and cleaved with *Hin*dIII and *Eco*RI, and the 4.4-kilobase pair (kb) fragment formed was isolated. The plasmid pSV2-gpt[32] was cleaved with *Pvu*II, ligated to the *Eco*RI linker dGGAATTCC and cleaved with *Eco*RI and *Hin*dIII, and the resulting 0.34-kb fragment containing the SV40 early gene promoter was isolated. The two DNA fragments thus obtained were ligated to yield the plasmid pSVACRα. pSVACRα was partially digested with *Pvu*II, ligated to the *Hin*dIII linker and cleaved with *Hin*dIII. The resulting 2.1-kb fragment containing the entire coding sequence for the AChR α-subunit was inserted into the *Hin*dIII site of pKCRH2 in the same orientation with respect to SV40 early gene transcription to generate the plasmid pKCRα1. The 0.70-kb *Pst*I–*Hin*dIII fragment derived from the 2.1-kb fragment described above was partially digested with *Rsa*I, ligated to the *Hin*dIII linker and cleaved with *Hin*dIII and *Pst*I. The resulting 0.34-kb fragment was isolated and ligated to the 4.1-kb *Hin*dIII–*Bam*HI fragment from pKCRH2 and the 2.1-kb *Bam*HI–*Pst*I fragment from pKCRα1, to yield pKCRα2. pACRβ56 was cleaved by *Nar*I, treated successively with alkaline phosphatase and with T4 DNA polymerase with the four dNTPs and ligated to the *Eco*RI linker. After digestion with *Eco*RI, the 4.1-kb fragment formed was isolated and ligated. The resulting plasmid was partially cleaved with *Pvu*II, ligated to the *Eco*RI linker and cleaved with *Eco*RI. The resulting 1.8-kb fragment containing the entire coding sequence for the AChR β-subunit was inserted into the *Eco*RI site in the β-globin gene sequence of pKCR327 in the same orientation with respect to SV40 early gene transcription to produce the plasmid pKCRβ1. The 1.2-kb *Eco*RI–*Pst*I fragment derived from the 1.8-kb fragment described above was partially digested with *Alu*I, ligated to the *Hin*dIII linker and cleaved with *Hin*dIII and *Pst*I. The 1.0-kb fragment formed was isolated and ligated to the 4.1-kb *Bam*HI–*Hin*dIII fragment from pKCRH2 and the 1.2-kb *Bam*HI–*Pst*I fragment from pKCRβ1, to yield pKCRβ2. pACRγ14 was partially digested with *Pvu*II, ligated to the *Hin*dIII linker, cleaved with *Hin*dIII and partially digested with *Eco*RI. The resulting 4.5-kb fragment was ligated to the 0.34-kb *Eco*RI–*Hin*dIII fragment of pSVACRα to yield the plasmid pSVACRγ. pSVACRγ was partially digested with *Pvu*II, ligated to the *Hin*dIII linker and cleaved with *Hin*dIII. The resulting 2.2-kb fragment containing the entire coding sequence for the AChR γ-subunit was inserted into the *Hin*dIII site of pKCRH2 in the same orientation with respect to SV40 early gene transcription to generate the plasmid pKCRγ1. The 1.4-kb *Bgl*II–*Pvu*II fragment derived from the 2.2-kb fragment described above was ligated to the *Hin*dIII linker, digested with *Hin*dIII and *Bgl*II and ligated to the 2.9-kb *Hin*dIII–*Pst*I fragment from pKCRH2 and the 2.2-kb *Pst*I–*Bgl*II fragment from pKCRγ1, to yield pKCRγ2. pACRδ8 was digested with *Pvu*II, ligated to the *Eco*RI linker and cleaved with *Eco*RI. The resulting 2.0-kb fragment containing the entire coding sequence for the AChR δ-subunit was inserted into the *Eco*RI site in the β-globin sequence of pKCR327 in the same orientation with respect to SV40 early gene transcription, to produce the plasmid pKCRδ1. The 1.1-kb fragment formed by cleaving the 2.0-kb fragment described above with *Eco*RI, *Pst*I and *Bcl*I was isolated, partially digested with *Hae*III, ligated to the *Eco*RI linker and cleaved with *Eco*RI and *Pst*I. The resulting 0.79-kb fragment was isolated and ligated to the 4.1-kb *Eco*RI–*Bam*HI fragment from pKCR327 and the 1.6-kb *Bam*HI–*Pst*I fragment from pKCRδ1, to yield pKCRδ2. For further experimental details, see ref. 33.

recombinant plasmids thus constructed is schematically illustrated in Fig. 1*b*; the plasmids containing the α-, β-, γ- and δ-subunit cDNAs are designated pKCRα2, pKCRβ2, pKCRγ2 and pKCRδ2, respectively (see Fig. 1 legend for experimental details).

Expression of functional AChR

Because the recombinant plasmids described above contain the replication origin of SV40, they are expected to propagate to high copy numbers in COS monkey cells[14], which produce SV40 T-antigen and are permissive for the replication of these recombinants. Therefore, each recombinant plasmid was introduced into COS cells by transfection[15]. S_1 nuclease mapping[16] of poly(A) RNA isolated from the transfected cells indicated that the 5′ end of the AChR subunit-specific mRNAs produced from the recombinant plasmids corresponded to the heterogeneous start sites of the transcripts formed under the control of the SV40 early gene promoter[12,17–19] and that the intronic sequence of the rabbit β-globin gene was eliminated. Thus, the AChR subunit-specific mRNAs produced in the transfected COS cells contained no AUG triplet upstream of the translation initiation site for the AChR subunit precursors[4–6]. The contents of the α-, β-, γ- and δ-subunit-specific mRNAs in poly(A) RNA from the transfected cells, as quantified by S_1 nuclease analysis, were respectively, 2.3–5.6 times, 2.6–6.8 times, 1.6–4.6 times and 0.9–1.4 times the level in *T. californica* electroplax poly(A) RNA.

To examine whether the AChR subunit-specific mRNAs produced from the recombinant plasmids could direct the synthesis of the functional AChR, we used the *Xenopus* oocyte translation system[20–22]. The mRNAs specific for the α-, β-, γ- and δ-subunits of the AChR, derived from transfected COS cells, were combined in the same ratio as in *T. californica* electroplax RNA and were introduced into oocytes by microinjection. Extracts from the injected oocytes, prepared 3 days later, exhibited ^{125}I-α-bungarotoxin binding activity ranging between 0.3 and 3 fmol per oocyte (see Table 1 and Fig. 4 legend for experimental details).

The injected oocytes, after incubation for 3 days, were studied electrophysiologically by recording the intracellular potentials or the membrane currents under voltage clamp[22]. The response to acetylcholine applied ionophoretically was examined in the presence of atropine which blocks the native muscarinic AChR present in the membrane of *Xenopus* oocytes[23,24]. Figure 2*a* shows that an inward current with a short latency was observed in response to acetylcholine. This response was virtually abolished within 3 min after the application of (+)tubocurarine (Fig. 2*b*), and the effect was reversible (Fig. 2*c*). The magnitude of the acetylcholine response depended on the membrane potential. The reversal potential of the acetylcholine response, measured in six injected oocytes under voltage clamp, was −5 to −1 mV. The reversal potential was not altered in a Cl^--free solution. When the ionophoretic application of acetylcholine was repeated at short intervals (10–20 s), the response was progressively diminished because of desensitization of the AChR. These results indicate that *Xenopus* oocytes injected with the four AChR subunit-specific mRNAs from transfected COS cells synthesize the functional AChR of the nicotinic type which increases the cationic conductances in response to acetylcholine. The electrophysiological properties of the AChR formed by translation of the mRNAs derived from the recombinant plasmids are in good agreement with those of AChR synthesized in oocytes injected with *Torpedo* electroplax poly(A) RNA[22].

The translation products encoded by the AChR subunit-specific mRNAs from transfected COS cells were identified by labelling them in oocytes with ^{35}S-methionine and analysing them by SDS-polyacrylamide gel electrophoresis after α-toxin affinity chromatography and immunoprecipitation. Figure 3*a* shows that oocytes injected with these mRNAs (lanes 6–8), like oocytes injected with *T. californica* electroplax poly(A) RNA (lanes 3–5), contained four polypeptides that were specifically precipitated with antiserum to the *T. californica* AChR and that were indistinguishable with respect to mobility from the subunits of the purified native AChR (lane 2) except for the γ-subunit. The γ-subunit synthesized in both groups of oocytes migrated somewhat faster than that of the purified native AChR; this may be due to a difference in glycosylation or other processing events *in vivo* or to proteolytic modification during the isolation procedure[1].

Effect of deletion of each subunit

In view of the conspicuous amino acid sequence homology found among the four subunits of the AChR and of their pseudosymmetric orientation across the membrane, proposed on the basis of their similarity in hydrophilicity profile and predicted secondary structure[4–6], the question arises as to whether or not all four subunits are required for receptor function. The expression system described above allowed us to examine this issue.

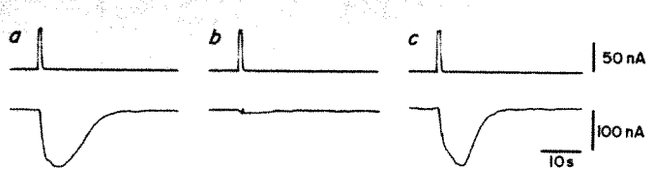

Fig. 2 Acetylcholine responses recorded for a *Xenopus* oocyte injected with the four AChR subunit-specific mRNAs produced from the recombinant plasmids in COS cells. The recordings were made at room temperature in a frog Ringer's solution containing 1 μM atropine: upper traces, currents used for ionophoresis of acetylcholine (backing current, 12 nA); lower traces, acetylcholine currents recorded under voltage clamp (downward deflection indicates inward current). The membrane potential was held at −60 mV, and acetylcholine was applied to the vegetal pole. Responses to acetylcholine before (*a*) and 2.5 min after perfusion with 2.5 μM (+)tubocurarine (*b*), and 15 min after washing out the antagonist (*c*).

Methods: COS monkey cells[14] were transfected with pKCRα2, pKCRβ2, pKCRγ2 or pKCRδ2 (20 μg of each recombinant DNA per 90-mm dish without carrier DNA) as described previously[33]. After 42–48 h, the cells were collected and total RNA was extracted as described elsewhere[34], except that the homogenization buffer contained 0.5% Nonidet P-40. Poly(A)-containing RNA was isolated by oligo(dT)-cellulose chromatography[35]. About 20 ng of poly(A) RNA, containing the α-, β-, γ- and δ-subunit-specific mRNAs, were injected into each oocyte of *Xenopus laevis*. The injected oocytes were incubated at 19 °C for 3 days in modified Barth's medium[20] containing gentamicin (0.1 mg ml^{-1}) and nystatin (50 U ml^{-1}). Oocytes having a healthy appearance were selected for subsequent studies.

Oocytes were injected with various combinations of three of the AChR subunit-specific mRNAs, and the resulting translation products were first analysed to ensure that the subunit polypeptides encoded by the three mRNAs injected were actually formed. For this purpose, the translation products, labelled in oocytes with ^{35}S-methionine, were subjected to immunoprecipitation with a mixture of four monoclonal antibodies[25], each specific for the individual subunits, and then to electrophoretic analysis. The results showed that every combination of three of the mRNAs introduced into oocytes directed the synthesis of the corresponding subunits, although the amounts of the polypeptides found were variable, depending on the particular mRNA combinations (Fig. 3*b*). In comparison with a control experiment in which all four mRNAs were injected (lane 2), smaller amounts of the respective subunits were generally present in oocytes when only three of the mRNAs were injected. Densitometric scanning of the fluorogram indicated that the levels of the α- and δ-subunits were especially low, being ~4%

Table 1 Effect of deletion of each subunit on AChR function

AChR subunit-specific mRNAs injected	^{125}I-α-bungarotoxin binding† (fmol per oocyte)	Response to acetylcholine* No. of responsive oocytes/no. of oocytes tested	Mean acetylcholine sensitivity‡ (mV μC^{-1})
α, β, γ, δ	2.06	126/170	37 (0.4–460)
β, γ, δ	<0.01	0/82	—
α, γ, δ	0.06	0/82	—
α, β, δ	0.09	2/82	1 (0.9–1)
α, β, γ	0.33	3/105	2 (0.2–4)
None	<0.01	0/80	—

Oocytes were injected with various combinations of the AChR subunit-specific mRNAs as indicated and were incubated for 3 days as described in Fig. 2 legend. The ^{125}I-α-bungarotoxin binding activity in the cell extract from each group of oocytes (24–110 oocytes per assay) was determined by the antibody precipitation assay[30] using a mixture of the four subunit-specific monoclonal antibodies (see Fig. 3 legend); incubation was at room temperature for 3 h in the presence of 5 nM ^{125}I-α-bungarotoxin (230 Ci $mmol^{-1}$). Acetylcholine potentials were recorded at a holding potential of −−70 mV; see Fig. 2 legend for further details.

* Our detectable limit of acetylcholine sensitivity was ~0.2 mV μC^{-1}.

† Means from assays of 106–343 oocytes.

‡ The means were calculated only for the responsive oocytes; the ranges of acetylcholine sensitivity are given in parentheses.

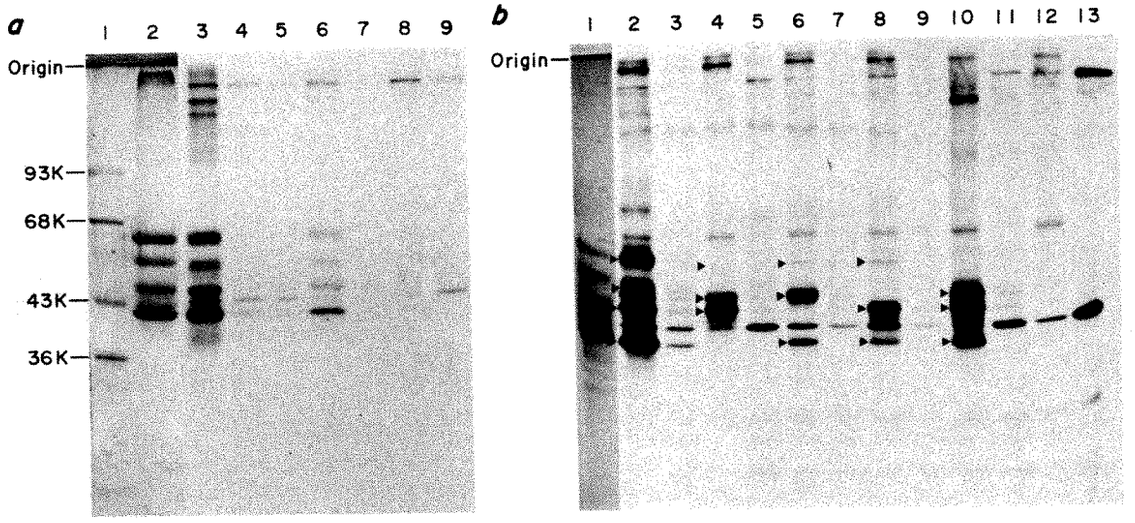

Fig. 3 Electrophoretic analysis of the translation products encoded by AChR subunit-specific mRNAs produced from recombinant plasmids in COS cells. Oocytes were injected with various combinations of the AChR subunit-specific mRNAs from transfected COS cells or with *T. californica* electroplax poly(A) RNA[35,36], then were incubated for 3 (*a*) or 2 (*b*) days in the presence of L-[^{35}S]methionine (1,440 Ci mmol^{-1}; final concentration 1 mCi ml^{-1}). The homogenate[21] of the oocytes was centrifuged at 100,000*g* for 60 min, and the supernatant (cell extract) was subjected to the following procedures. In ***a***, each cell extract was shaken with *Laticauda semifasciata* III–Sepharose. After washing, the AChR was eluted with 1 M carbamylcholine, immunoprecipitated with rabbit antiserum to intact *T. californica* AChR and protein A–Sepharose, and electrophoresed on a SDS/10% polyacrylamide gel[37]. The fluorograms[38] of the electrophoretic analyses (lanes 3–9), together with the standard polypeptides stained with Coomassie brilliant blue (lanes 1 and 2), are shown. Lane 1, size markers: rabbit lactate dehydrogenase [molecular weight (M_r) 36,000 (36K)], chicken ovalbumin (M_r 43K), bovine serum albumin (M_r 68K) and rabbit muscle phosphorylase *b* (M_r 93K). Lane 2, α-, β-, γ- and δ-subunits (from bottom to top) of native *T. californica* AChR purified by α-toxin affinity chromatography[39]. Lane 3, AChR preparation derived from 33 oocytes injected with *T. californica* electroplax poly(A) RNA. Lane 4, a control for lane 3 (immunoprecipitate obtained in the presence of a large excess of native *T. californica* AChR). Lane 5, another control for lane 3 (immunoprecipitate obtained with non-immunized rabbit serum). Lane 6, AChR preparation derived from 100 oocytes injected with the α-, β-, γ- and δ-subunit-specific mRNAs. Lane 7, a control for lane 6 (like lane 4). Lane 8, another control for lane 6 (like lane 5). Lane 9, immunoprecipitate derived from 100 oocytes injected with poly(A) RNA from non-transfected COS cells. In ***b***, 51 ng of purified native *T. californica* AChR as carrier was added to each homogenate derived from 80 injected oocytes, and each cell extract was subjected to prior treatment with non-immunized rabbit serum and protein A–Sepharose to diminish co-precipitation of nonspecific proteins. Immunoprecipitation was done using a mixture of the four subunit-specific monoclonal antibodies[25] (2.6 pmol each of monoclonal antibodies (against intact AChR) mAb5, mAb111, mAb154 and mAb137 specific for the α-, β-, γ- and δ-subunits of the *T. californica* AChR, respectively) and anti-rat immunoglobulin–Sepharose. The resulting immunoprecipitates were electrophoresed on a SDS/10% polyacrylamide gel: lane 1, subunits of native *T. californica* AChR stained; lanes 2, 4, 6, 8, 10 and 12, fluorograms of the electrophoretic analyses of the immunoprecipitates derived from oocytes injected with the α-, β-, γ- and δ-subunit-specific mRNAs (lane 2), the β-, γ- and δ-subunit-specific mRNAs (lane 4), the α-, γ- and δ-subunit-specific mRNAs (lane 6), the α-, β- and δ-subunit-specific mRNAs (lane 8), the α-, β- and γ-subunit-specific mRNAs (lane 10) and poly(A) RNA from non-transfected COS cells (lane 12). Lanes 3, 5, 7, 9, 11 and 13 are controls for lanes 2, 4, 6, 8, 10 and 12, respectively (immunoprecipitates obtained in the presence of a large excess of native *T. californica* AChR). The AChR subunits derived from the oocytes are indicated by arrowheads.

(lanes 6 and 8) and ~1% (lane 4) or ~3% (lanes 6 and 8) of the control value, respectively, except for the α-subunit (~20%) found in the absence of the δ-subunit (lane 10). On the other hand, the levels of the β-subunit (lanes 4, 8 and 10) and the γ-subunit (lanes 4, 6 and 10) were relatively high, being ~30 to ~80% of the control value. These observations suggest that the subunit polypeptides, when one of them is lacking, are more readily degraded in oocytes or during the isolation procedure, although the possibility of different rates of their synthesis cannot be excluded. The absence of one subunit may hinder the assembly of the remaining subunits or lead to the formation of an aberrant complex, thus reducing the stability of the constituent polypeptides. It is interesting in this context that, in the absence of the δ-subunit, fairly large amounts of the remaining three subunits, including the otherwise unstable α-subunit, were found. Thus, the coexistence of the β- and γ-subunits seems to stabilize the α-subunit, presumably by forming a complex of these three subunits with a relatively correct conformation. On the other hand, the δ-subunit seems to be stabilized only when all of the three other subunits are present.

In the experiments shown in Table 1, oocytes injected with various combinations of three of the AChR subunit-specific mRNAs were tested for ^{125}I-α-bungarotoxin binding activity in the cell extract as well as for the response of the membrane potential to acetylcholine. The cell extracts containing all but the β-, γ- or δ-subunit exhibited 3, 4 and 16%, respectively, of the α-bungarotoxin binding activity of the complete AChR synthesized in oocytes, whereas the cell extract containing all but the α-subunit showed no detectable activity. The extent of α-bungarotoxin binding seems to correlate with the amount of the α-subunit present (see above and Fig. 3*b*). This is consistent with the finding that the isolated α-subunit alone is capable of binding α-bungarotoxin[26,27].

The cell extract containing all four subunits and that containing all but the δ-subunit, which exhibited a relatively high level of α-bungarotoxin binding activity, were tested for the protective effect of an agonist on α-toxin binding[28]. Figure 4 shows that, in the presence of carbamylcholine at increasing concentrations, the ^{125}I-α-bungarotoxin binding activity in both of the cell extracts decreased gradually. The carbamylcholine concentration required for 50% protection of the complete AChR was essentially the same as that observed for the native *T. californica* AChR, suggesting that the AChR encoded by the mRNAs produced from the recombinant plasmids possesses an agonist binding site having normal affinity. An approximately fivefold higher concentration of carbamylcholine was required for 50% protection of the AChR lacking the δ-subunit; the apparent binding affinity of α-bungarotoxin was lower for the

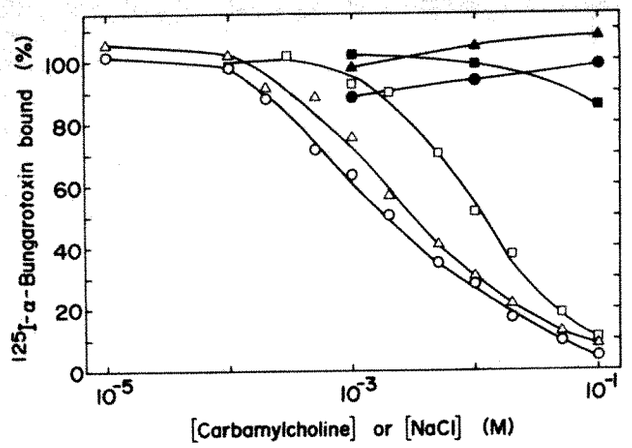

Fig. 4 Effect of carbamylcholine on ^{125}I-α-bungarotoxin binding. Cell extracts prepared from oocytes injected as indicated, or purified native *T. californica* AChR dissolved in the homogenization buffer[21], were preincubated at room temperature for 10 min with carbamylcholine at the specified concentrations and were then mixed with ^{125}I-α-bungarotoxin (230 Ci mmol^{-1}; final concentration 7 nM); the concentration of the toxin-binding site was 63–78 pM. After incubation at room temperature for 3 h, the amount of the toxin bound was determined by the antibody precipitation method[30] using rabbit antiserum to native *T. californica* AChR. ○, Extract from oocytes injected with the α-, β-, γ- and δ-subunit-specific mRNAs from transfected COS cells (●, control experiment in which carbamylcholine was replaced by NaCl at the indicated concentrations). □, Extract from oocytes injected with the α-, β- and γ-subunit-specific mRNAs from transfected COS cells (■, control experiment as above). △, Purified native AChR (▲, control experiment as above). The apparent K_D value for ^{125}I-α-bungarotoxin, estimated by varying the toxin concentration at a fixed concentration (20–43 pM) of the toxin-binding site[40], was 0.1 nM for the native AChR, 0.2 nM for the AChR from oocytes injected with the four subunit-specific mRNAs and 0.7 nM for the AChR from oocytes injected with the α-, β- and γ-subunit-specific mRNAs.

AChR lacking the δ-subunit than for the complete AChR (see Fig. 4 legend). These results imply that the agonist binding site is formed even in the absence of the δ-subunit, but its binding affinity is lower than in the intact AChR molecule.

Of the oocytes injected with all four AChR subunit-specific mRNAs, 74% responded to acetylcholine, when tested electrophysiologically (Table 1). In contrast, the oocytes injected with three of the mRNAs exhibited no acetylcholine potential, except that 2–3% of the oocytes injected with all but the γ- or δ-subunit-specific mRNA showed a weak (+)tubocurarine-sensitive response. The mean acetylcholine sensitivity[29] of the responsive oocytes, expressed as the acetylcholine potential amplitude (mV) divided by the quantity of electricity (μC) used for ionophoresis of acetylcholine, was 37 mV μC^{-1} for the oocytes with the complete AChR, but was 1–2 mV μC^{-1} for those with AChR lacking the γ- or δ-subunit.

In view of the low levels of the α- and δ-subunits found in the oocytes injected with three of the AChR subunit-specific mRNAs (see above and Fig. 3*b*), we examined the effect of reducing the amount of a mixture of the four mRNAs injected into oocytes on their responsiveness to acetylcholine. When oocytes were injected with a mixture of the four mRNAs diluted 10-fold with poly(A) RNA from non-transfected COS cells, 59% of the oocytes (22 out of 37) still responded to acetylcholine with a mean sensitivity of 3 mV μC^{-1} (range 0.3–14 mV μC^{-1}), but the ^{125}I-α-bungarotoxin binding activity as well as the amounts of the α- and δ-subunits found in the oocytes treated in the same manner ranged between barely detectable levels and ~4% of the values obtained for the oocytes injected with a normal mixture of the four mRNAs. Therefore, the amounts of the individual subunits present in the oocytes injected with all but the β-, γ- or δ-subunit-specific mRNA (~3 to ~40%, ~3 to ~30% and ~20 to ~80% of the control value, respectively) would be sufficient for many of these oocytes to respond to acetylcholine. The amount of the δ-subunit present in the oocytes injected with all but the α-subunit-specific mRNA (~1% of the control value) might be limiting, but it is hardly conceivable that the AChR lacking the α-subunit can be functional because this subunit is principally responsible for binding acetylcholine[1].

Thus, our results suggest that all four subunits are required for normal AChR function. The possibility remains that the γ- and δ-subunits can replace each other to some extent for the receptor function because 2–3% of the oocytes injected with all but the γ- or δ-subunit-specific mRNA responded to acetylcholine, albeit slightly. However, the aberrant presence of the nicotinic AChR in non-injected oocytes cannot completely be excluded. The expression system described here will be useful for studying the structure–function relationship as well as the antigenic determinants of the AChR by introducing mutations into this molecule.

We thank Dr Charles Weissmann for the plasmid pKCR327, Dr Paul Berg for pSV2-gpt, Dr Yakov Gluzman for COS cells, Dr Michiaki Kohno for the purified *T. californica* AChR and Dr Katumi Sumikawa for helpful advice. This investigation was supported in part by research grants from the Ministry of Education, Science and Culture of Japan, the Mitsubishi Foundation and the Japanese Foundation of Metabolism and Diseases.

Two configurations of a channel-forming membrane protein

P. N. T. Unwin & P. D. Ennis

Department of Structural Biology, Stanford University School of Medicine, Stanford, California 94305, USA

The protein oligomer forming the gap junction channel has been analysed in two Ca^{2+}-sensitive states by electron microscopy of membranes in frozen aqueous solutions. Switching between states occurs by a small cooperative rearrangement involving tilting of the subunits, which may be responsible for the effect of Ca^{2+} on channel permeability in vivo.

FUNDAMENTAL biological processes such as the transmission of nerve impulses, visual excitation and cell-to-cell communication depend on the fact that membranes can regulate the passage of ions and/or small molecules across their surfaces. Proteins create channels in the membranes for this purpose and regulation is achieved by conformational changes of the protein in response to chemical or electrical stimuli. An example of such a protein is the one which forms the gap junction (or cell-to-cell) channel. We report here on its structure and action when stimulated by Ca^{2+}, an ion which induces this channel to close[1,2].

The protein is a cylindrical oligomer composed of six identical, rod-shaped subunits[3,4]. It spans the lipid bilayer, creating a channel along its central, hexad, axis. The channel traverses the plasma membranes of two apposed cells in consequence of a hexamer in one membrane being joined symmetrically to an oppositely facing hexamer in the other. These 12-subunit assemblies accumulate at specialized regions of contact (gap junctions), where they regulate the passage of small molecules and ions between cell interiors (reviewed in refs 5, 6).

Based on the appearance of gap junction surfaces in negative stain, we speculated that the channel might open and close, given the appropriate stimulus, by a coordinated tilting and sliding motion of the protein subunits along their lines of contact[4]. Subsequent X-ray diffraction experiments showed that a reversible transition of this nature could be induced by the action of Ca^{2+} *in vitro*[7]. Now we describe the two Ca^{2+}-sensitive configurations seen more directly in electron micrographs of junctions in frozen aqueous solutions. The three-dimensional maps obtained by this technique[8,9] reveal features of the subunits extending over their entire length, both within the lipid bilayer and in the aqueous spaces on either side. Differences between these maps demonstrate that Ca^{2+} does induce a small coordinated rearrangement of the subunits around the channel and affect its dimensions in a manner consistent with the original proposal.

Imaging and diffraction

We made one preparation of rat liver junctions for these experiments and produced two alternative structures by dialysing separate portions against Ca^{2+}-free (5 mM EGTA, 0.5 mM $MgCl_2$, 5 mM HEPES *p*H 8.0) and Ca^{2+}-containing (0.05 mM $CaCl_2$, 5 mM HEPES *p*H 8.0) solutions. Methods were as described previously[7]. Such junctions are double membrane plaques, 0.5–1.5 μm in diameter, composed of ordered domains of oppositely facing hexamers and intervening lipid molecules. The hexamers pack within the domains on a hexagonal lattice of dimension 80–85 Å and protrude into the space between the two membranes, making a gap between them of ~30 Å.

Electron microscopy was used to derive a set of three-dimensional Fourier terms corresponding to each structure. The junctions were frozen in their respective solutions and examined with a cold stage at −120 °C. Images were recorded of specimens tilted at angles of up to 53° to the incident 100-kV electron beam (Fig. 1). Densitometry and computer processing were carried out as described previously[4,10] and the Fourier terms to 20 Å resolution from each image were combined according to the symmetry of the space group P6. The average phase errors in combining the data were 16.7° and 15° for the $-Ca^{2+}$ and $+Ca^{2+}$ structures, respectively, based on comparisons between each new phase and all previously accumulated values related by symmetry. For both structures, 18 images provided sufficient values of amplitude and phase to map out the continuous variations along each of the five crystallographically independent reciprocal lattice lines. Curves were fitted to the data along the lattice lines by a least-squares method[11], with the amplitude curves weighted according to the reliability of the corresponding phases (Fig. 2). These curves, sampled at regular intervals (0.002 $Å^{-1}$), provided the Fourier terms for calculating three-dimensional maps.

There were cones of missing information due to the restricted ranges of tilt. By far the most significant omissions, according to X rays[7], were the terms from the central (0, 0) lattice line. These terms determine only the absolute levels of the contours in sections parallel to the membrane and therefore have no influence on the positions of peaks identifying the paths taken by the protein subunits, described below. They do, however, affect the dimensions of features bound by shallow gradients, for example the channel. Such dimensions were obtained more accurately previously[4] with complete sets of Fourier terms.

X-ray diffraction was used (as in ref. 7) to provide an independent evaluation of the structures. The partially oriented gap junction pellets gave rise to intensities along the lattice lines which were smeared into concentric arcs. Traces across these arcs, obtained by circular integration, were very similar to analogous profiles calculated from the electron microscopic data (Fig. 2, panel 6). Moreover, in comparing the two structures,

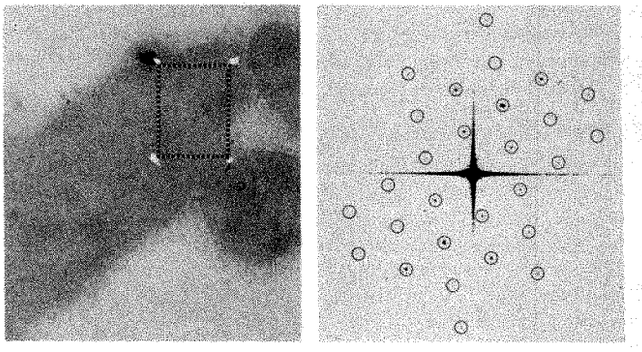

Fig. 1 Image (×32,000) and optical diffraction pattern (from the boxed area) of a gap junction frozen in Ca^{2+}-free solution and tilted 31.5° to the incident electron beam. The regular hexagonal lattice is evident from the array of diffraction peaks encircled, but is barely visible in the image because of the small differences in electron scattering properties between ice, lipid and protein.

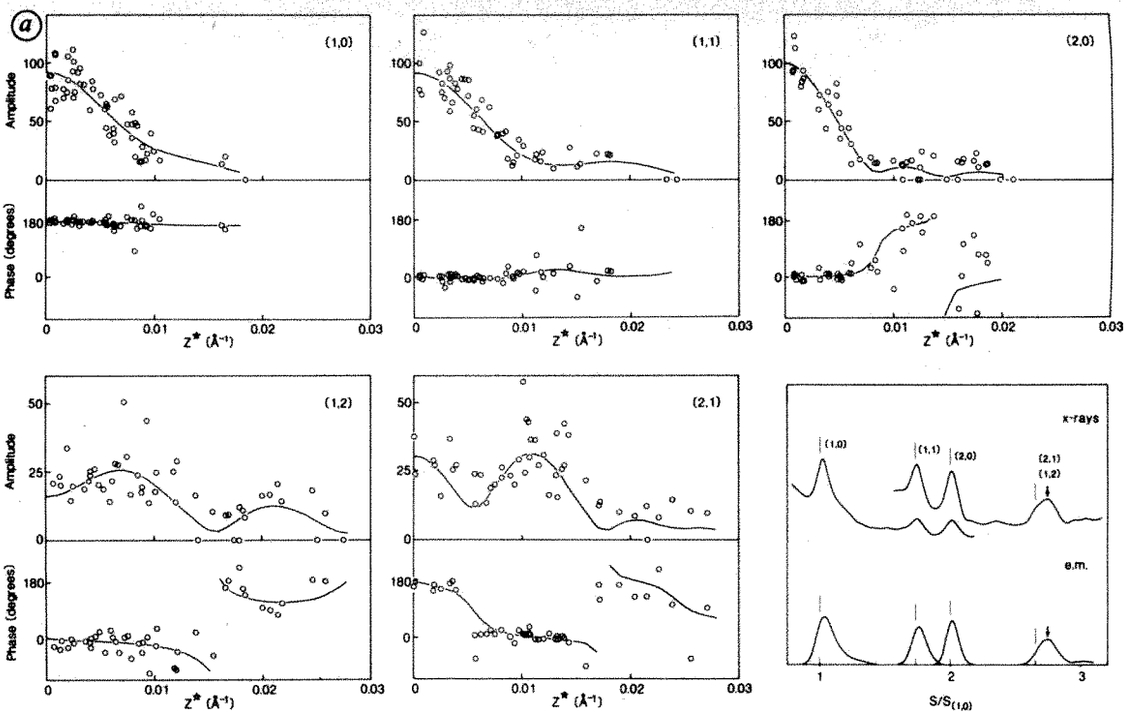

Fig. 2 Diffraction data from gap junctions in: *a*, Ca^{2+}-free solution; *b* (right), Ca^{2+}-containing solution. The values of amplitude and phase along the reciprocal lattice lines (first five panels) were derived from images of junctions tilted to the incident electron beam by angles of up to 53° in *a* and 50° in *b*. Z^* is the distance from the midpoint along the lattice line; the Friedel relationship gives the values for negative Z^*. The sixth panel shows X-ray traces.

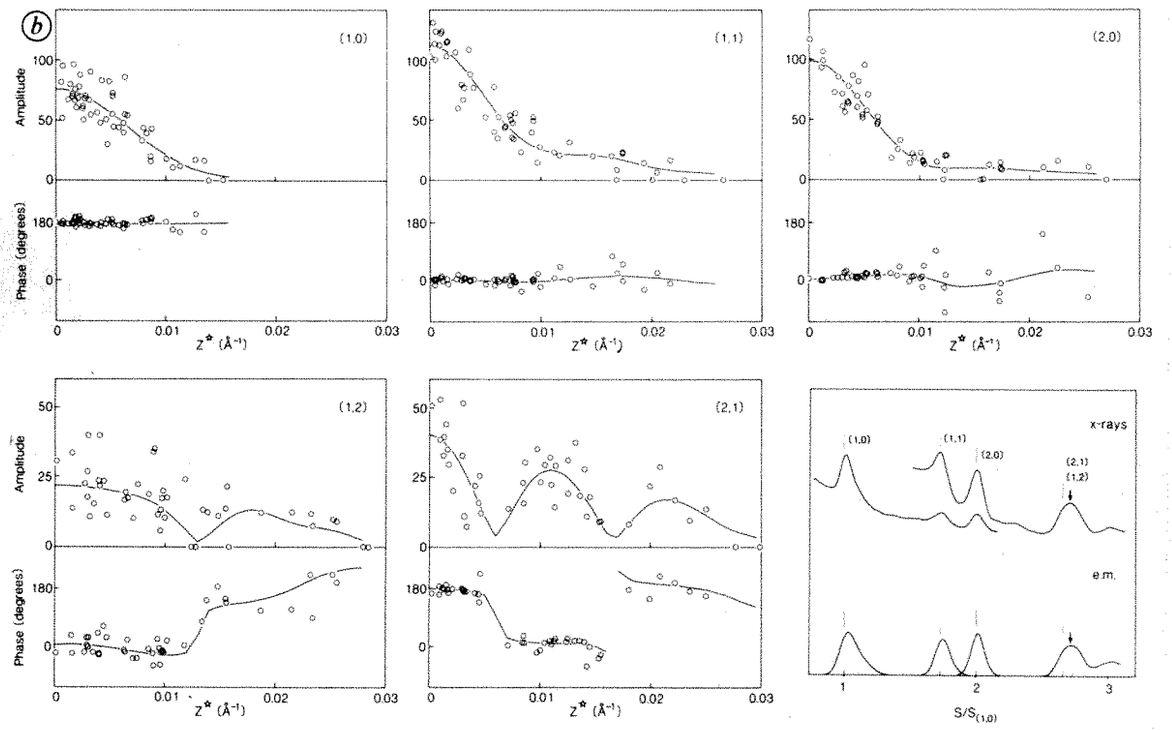
Methods: Specimens were prepared by the double carbon film technique[8,20]. The carbon support grid containing the junctions was immersed in 10× diluted Ca^{2+}-free or Ca^{2+}-containing solution, raised through a second carbon film floated on the surface, pressed firmly onto Millipore filter paper, held away from the filter paper for several seconds and then plunged into liquid nitrogen. Holes in the support film were important for efficient withdrawal of excess solution onto the filter paper. After transfer to the microscope, the grids were maintained at ~−120 °C using a modified Philips EM300 high-resolution stage[21]. Images were focused using an off-axis viewing screen[22], and recorded at a magnification of ×28,000 on Kodak 4463 film with low doses (2–5 electrons $Å^2$) to minimize radiation damage. Films were developed in full strength Kodak D19 developer for 8 min. Tilting was accomplished by bending the microscope grids under liquid nitrogen before inserting them into the stage. Preliminary selection of images was by optical diffraction evaluation of the strength of the Fourier terms and of the focus levels indicated by the positions of the zeros between the Thon rings[19]. Images only gave suitable diffraction patterns if they were of specimens surrounded by visible films of ice. Those images selected for subsequent processing and incorporation into the three-dimensional data sets all had underfocus values within the range: 4,000–12,000 Å; thus, variations in strengths of the Fourier terms due to different contrast transfer functions were small. In the processing, the densitometer step and sampling sizes were 20 μm, equivalent to 7 Å at the specimen, and the array size for Fourier transformation was 512×512. An analysis of images very close to focus indicated that the poorer contrast transfer at low spatial frequencies, produced by underfocusing, weakened the amplitude of the (1, 0) peak by up to 30% relative to values for the other peaks; the same correction was applied to all images for this effect. Tilt angles and axes were estimated from the geometry of the peaks in the computed Fourier transforms and from focus changes across the film. In combining the Fourier terms from different images, the comparison range used along Z^* was 0.0022 $Å^{-1}$. Images were not incorporated into the three-dimensional data sets if the phase residuals, based on comparisons with the previously accumulated phases, were greater than 25°. With specimens tilted by >45°, some of the terms were omitted from the refinement. Unlike previously[4], junctions from this preparation were strongly chiral (see also ref. 23), a feature most obvious from the opposite phases of the (1, 2) and (2, 1) peaks at low values of Z^*. Seven of the 18 images for *a* and 8 of the 18 images for *b* were of junctions with their positive crystallographic direction pointing towards the electron source. The X-ray traces (panel 6) were obtained from partially oriented pellets, as described previously[7]. The dimensionless parameter, $S/S_{(1,0)}$, provides a linear reciprocal scale such that the hexagonal lattice positions, marked by vertical lines, are at 1, $\sqrt{3}$, 2 and $\sqrt{7}$. Peak values depart from these positions depending on the strength of the Fourier terms along the lattice lines away from the point, $Z^*=0$. The electron microscopy-derived curves compared were obtained by plotting the amplitudes against reciprocal spacing, rather than Z^*, squaring to obtain intensities and convolving these intensities with a gaussian distribution to simulate the broadening of the X-ray peaks due to finite beam size and disorder. Changes in the position of the overlapped (2, 1) and (1, 2) peak (arrows) and in the intensity of the (1, 0) peak represent the most significant differences between the two structures. These changes are consistently observed in the X-ray patterns[7].

the same differences (displacement of the overlapped (2, 1) and (1, 2) peak; change in intensity of the (1, 0) peak) were indicated by X rays as by electrons. Therefore, we presume that the protein configurations being visualized at −120 °C are the same as those at more natural temperatures.

Three-dimensional maps



The maps, synthesized from the two sets of Fourier terms, depict the protein subunits surrounding the channels and extending through the lipid bilayer into the aqueous spaces on either side (Fig. 3). The subunits have several features of interest. They are rods which in cross-section must taper significantly towards the hexad axis. They are tilted tangentially and radially around the channel (see below). They appear more distinct and slightly thicker in the bilayer than in the extracellular region, as if their secondary structures in the two environments are quite different.

Ice and lipid are not separately resolved because of their similar mean electron scattering densities. Thus, the maps do not reveal accurately the extents to which the subunits protrude from the bilayer. However, the surface details seen with negative stain[4] correspond to features in Fig. 3 and suggest that the subunits protrude from the bilayer only slightly on the cytoplasmic side (5–10 Å) compared with the extracellular side (15–20 Å).

The hexamers come closest to each other inside the bilayer and the way they fit into the crystalline lattice depends on the bilayer in question. In Fig. 3 the ridges on the sides of the hexamers interlock, forming the same neighbour-to-neighbour relationship in both maps, while in the other bilayer they abut. The latter hexamers are less well preserved, and probably distorted, as the density fluctuations associated with their subunits are weaker (by 45% and 15% for the $-Ca^{2+}$ and $+Ca^{2+}$ structures, respectively). These effects may reflect constraints on the potentially more open packing due to the restricted volume of lipid present or due to the curved membranes of isolated junctions[12] being forced to lie flat. More symmetrical packing[4] presumably occurs when more lipid is available to fill intervening spaces.

Differences

The hexamers look different in the two maps because of the different subunit configurations. They also have a slightly smaller

diameter in the $+Ca^{2+}$ structure, where the lattice dimension is almost 2 Å less[7]. We analysed the differences by comparing the tangential and the radial displacements of the peaks around the channel at various levels through the two structures. In projection down the hexad axis (Fig. 4) these peaks follow curved paths which are more foreshortened for the $+Ca^{2+}$ than for the $-Ca^{2+}$ subunits. The $+Ca^{2+}$ subunits, then, are aligned more nearly parallel to the hexad axis. From the direction and magnitude of foreshortening we find that the two paths of the subunits are related, approximately, by a tilt of ~7.5° tangential to the hexad axis and about the extracellular end (compare Fig. 4*b* and *c*).

The radial path changes of the subunits in going to the $+Ca^{2+}$ configuration are small: about 2 Å inwards towards the cytoplasmic end, but outwards towards the extracellular end (Fig. 5). As shown, the constricting action at the cytoplasmic end would be expected from a tilt strictly tangential to the hexad axis. However, the opposite action at the other end is an additional feature, increasing slightly the separation between neighbouring subunits in the part of the structure outside the cell. This could be needed for the subunits to fit into the 'tighter' configuration without being deformed.

The significance of the small radial changes was checked by calculating difference Fourier maps between the two structures. In these maps the displacement of matter into and away from the channel is seen as two peaks of opposite sign, centred on the hexad axis and near the two ends of the subunits. The peaks were present in both membranes and did not depend on which way up one structure was with respect to the other. Further, the major difference terms responsible for the peaks were significant at the 5% level, based on the standard deviations of the observed amplitudes along the contributing reciprocal lattice lines.

Switching between the two structures

The three-dimensional maps revealed several basic features of this channel-forming protein, It has a length of ~70 Å perpendicular to the plane of the membrane and an average diameter of ~64 Å within this plane. It occupies a space of ~225,000 $Å^3$ (from the zero-level contour), consistent with the value estimated from the subunit molecular weight, 28,000 daltons (refs 13, 14), assuming 1.3 $Å^3$ per dalton for the partial specific volume. It is composed of two main portions, one within and the other outside the membrane, which differ distinctly in

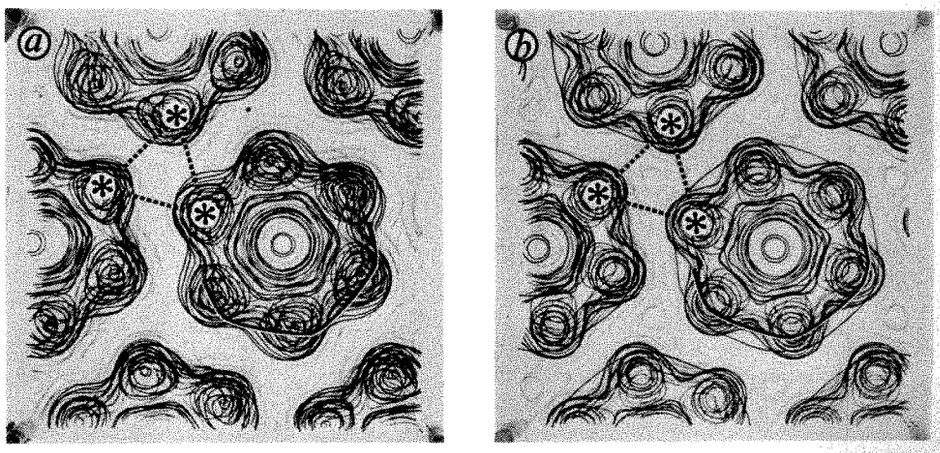


Fig. 3 Maps of the $-Ca^{2+}$ (*a*) and $+Ca^{2+}$ (*b*) structures in one of the membranes, as they would appear viewed from the inside of the cell. The distance between channels in *a* is 82.4 Å and in *b* it is 80.6 Å, from X rays[7]. The six surrounding protein subunits create strong fluctuations in density within the lipid bilayer, but weaker fluctuations in the aqueous extracellular space (furthermost portion of hexamer, outer surface partly outlined). All hexamers have the same neighbour-to-neighbour relationship where they come closest to each other, near the middle of the bilayer (indicated by equivalent triangles connecting equivalent points in the two maps). The positive and zero-level contours (darker) correspond to regions of higher electron scattering density. Detail extends over a distance of 68 Å perpendicular to the sections; fluctuations in density outside the maps on the cytoplasmic side are less than one contour level.

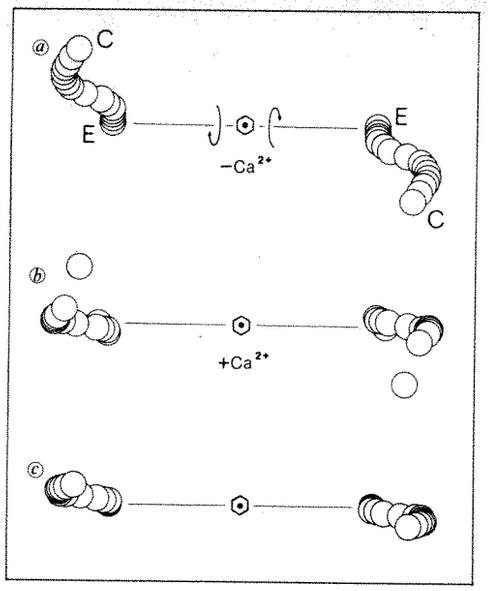

Fig. 4 Projection down the hexad axis of paths taken by subunits on opposite sides of the channel: *a*, $-Ca^{2+}$ and *b*, $+Ca^{2+}$ structures; *c*, path derived from *a* assuming a tilt of 7.5° about the radial axis is indicated. The circles mark the peak positions in sections parallel to the membrane through the three-dimensional maps. E and C are the extracellular and cytoplasmic ends of the subunits, respectively, corresponding to the top and bottom sections in Fig. 3. Correspondence between *c* and *b* indicates that the paths in *a* and *b* are related, approximately, by a small tilt tangential to the hexad axis.

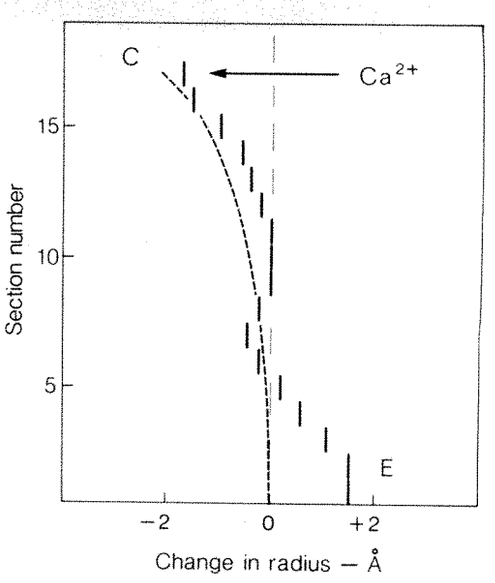

Fig. 5 Radial displacements of the subunits relative to the hexad axis (vertical) on addition of Ca^{2+}, determined from the positions of peaks around the channel in sections through the three-dimensional maps. The broken line shows the radial displacement corresponding to the tilt *a* to *c* in Fig. 4. E and C are as in Fig. 4. Similar radial displacements are suggested by the negative stain maps (ref. 4, Fig. 4), which show a decrease and an increase in stain accumulation in the cytoplasmic and extracellular parts of the channel, respectively.

appearance. In detail, the structure appears rather different from that determined from mouse liver gap junctions[3,12].

Calcium acts to produce small variations in these features by changing, or switching, the configurations of the subunits. From the differences in configuration investigated above, the switch must entail motion of essentially rigid rods having surfaces which do not rotate about the rod axes, but continue to point in the same directions. At low resolution, therefore, it consists simply of a rearrangement of the subunits by tilting and sliding along their lines of contact. This observed mechanism by which the protein changes its structure confirms the one proposed[4], based on the appearance of gap junction surfaces in negative stain.

What is the effect of calcium on the dimensions of the channel? The rearrangement is depicted by wooden models (Fig. 6). We found that subunits on either side of the channel become aligned more nearly parallel to it on exposure to Ca^{2+}. They tilt in opposite senses about a radial axis at the extracellular end (bottom of model) and consequently are displaced tangentially towards each other at the cytoplasmic end (top of model). The change in tilt of each subunit is only ~7.5°, but the protein is long, so that its displacement at the cytoplasmic end is quite large, that is, $\sim 70 \sin 7.5 = 9$ Å. Thus the channel-lining faces of each pair of subunits (not visualized at this resolution) could, in principle, move towards each other by up to ~18 Å in the cytoplasmic region of the structure. Such a constricting action may provide the means of controlling channel permeability, as it occurs in the part of the protein where the structure changes most and where the channel appears to close[4]. A restrictive opening of 16–20 Å diameter is predicted by permeability measurements made on mammalian cells[15,16].

The switching between configurations seen here appears able to accomplish a large change in channel dimensions without the individual polypeptide chains becoming grossly distorted, losing contact or moving over each other by distances of more than a few angstroms. Tilting of the subunits tangential to the channel has a crucial role in mediating this action. Energetically unfavourable interactions are avoided by the subunits moving predominantly parallel to the plane of the bilayer and keeping the same polar and hydrophobic surfaces exposed to the solvent

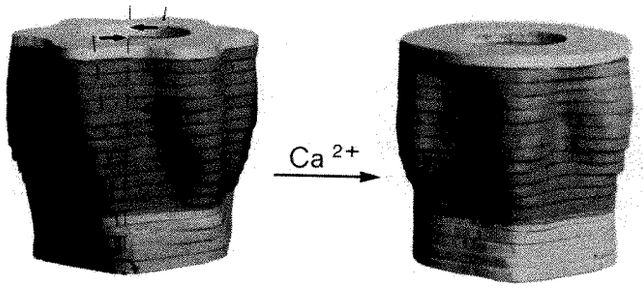

Fig. 6 Models of the two protein configurations, constructed from the maps in Fig. 3. The lighter shaded portions correspond to parts of the protein contacting fluid inside (top) and outside (bottom) the cell; the darker shaded portion would be in contact with lipid. The configurations are related to each other by tilt axes passing radially through the bases of the subunits (as depicted on the left-hand model). Subunits on either side of the channel tilt in opposite directions about these axes, and the resulting tangential displacements (pair of arrows) are greatest at the upper, cytoplasmic face.

and lipid. It is a cooperative mechanism, as the subunits must change their mode of packing together, and may be analogous to the transitions which occur in spherical and helical virus particles[17,18], controlled by divalent cation concentration or *p*H. Other oligomeric membrane proteins may respond to chemical or electrical stimuli by undergoing similar rearrangements predominantly within the plane of the bilayer.

We thank Chris Raeburn for constructing the electron microscope cold stage used in this work. We also thank David Agard, David Grano, Ron Milligan and Guido Zampighi for their help. Computing facilities were generously provided by Dr L. Herzenberg. The research was supported by grants from the NIH and American Cancer Society.

Implications of 10^{16} eV γ rays from Cyg X-3

David Eichler

W. Thomas Vestrand

Physics Department, University of New Hampshire, Durham, New Hampshire 03824, USA

Samorski and Stamm[1] have reported and Lloyd-Evans *et al.*[2] have recently confirmed the detection of high-energy quanta, presumably γ rays, with energies $E > 2\times10^{15}$ eV from Cygnus X-3. These ultra-high energy (UHE) γ rays were detected with extensive air shower arrays and included four events with $E > 10^{16}$ eV. Temporal analyses[1,2] of the events indicate that the flux is modulated with a 4.8-h period and is sharply pulsed. Here (1) we discuss the implications of these γ-ray detections and suggest that autocorrelating the air shower data may be the best way to determine the intrinsic width of the γ-ray pulses; (2) we argue that the radiating particles are accelerated by a pulsar and that if they are accelerated according to any pulsar mechanism we know of, then they must be ions; (3) we note that if the ions are accelerated to 10^{16} eV by a large amplitude Deutsch wave, then the gravitational wave luminosity L_g should exceed that of the Crab pulsar by a factor of $\sim5\times10^5$, and the spin-down time should be ~80 yr (requiring a truly remarkable object); and (4) we show that the ions can be accelerated in the near zone but only if, contrary to the standard view, pair production does not greatly reduce the vacuum potential drop in the near zone. We note that near-zone acceleration could be confirmed by detection of curvature radiation.

Several groups have detected γ rays from the Cyg X-3 system at energies $<10^{15}$ eV using atmospheric Cerenkov techniques. The system is known to be a luminous ($L_{peak} > 10^{37}$ erg s^{-1}) source of TeV γ rays[3–5]. The flux at TeV energies is periodic and has the same 4.8-h periodicity seen in medium energy γ rays[6] (~10^2 MeV), X rays[7], and at IR energies[8] and is generally identified as the orbital period. The TeV light curve is composed of two narrow pulses separated by ~1.9 h (ref. 3), and roughly centred about the X-ray minimum. A possible detection of γ rays having energies in the range 10^{14}–10^{15} eV is reported by Bhat *et al.*[9], who studied the arrival times of atmospheric Cerenkov pulses produced by air showers with energies $E > 10^{14}$ eV. By autocorrelating their data they found a significant excess of events with time separations $\Delta t < 40$ s that had a sidereal association. The width of the directional enhancement peak in right ascension is comparable to the angular response function of the detection system. Their data is consistent with a point source at a right ascension of 20 ± 1 h. The detection system was stationed at Gulmarg, India (latitude 34° N) and pointed at the zenith. It is tempting to identify this nonrandom air shower component with γ rays from Cyg X-3 ($\alpha = 20$ h 31 min, $\delta = 40°\,47'$). However, the required flux would have to be roughly a factor of three larger than the upper limit of Fegan and Danaher[10] and several orders of magnitude higher than the value obtained by interpolating between measurements at 10^{15} eV and below 10^{13} eV. Nevertheless, we feel that autocorrelating the data may be the best way to determine the intrinsic width of the γ-ray pulses since small errors in the ephemeris will broaden pulses in phase histograms that are generated using data obtained over long periods of time. Taken at face value, the observations of Bhat *et al.*[9] indicate an excess only for $\Delta t < 40$ s (the autocorrelation was done only up to $\Delta t = 450$ s) and require the pulses to be extremely narrow ($\Delta\phi = 2\times10^{-3}$). We feel that an autocorrelation analysis of data obtained by a detection system with better angular resolution could be useful for determining whether or not the pulses are actually this narrow.

A natural interpretation of the narrow pulses is that Cyg X-3 is a young pulsar in a binary system[11] that is emitting UHE particles which interact with the corona of the companion star[12]. Most of the UHE emission should come from a translucent 'window' (optical depth $\tau \sim 1$) in the companion star's corona, which may be extremely variable and complex due to its interaction with the pulsar wind. Higher τ would obscure the photons, and lower τ would be inefficient as a scintillation screen. It seems reasonable that the translucency condition is fulfilled, during any given orbital period, for 40 s which would account for the autocorrelation time scale. If the pulse width is actually this narrow, the intrinsic luminosity of the system must be $L > 1.3\times10^{39}$ erg s^{-1}; this would rank the pulsar as the youngest known.

The production of γ rays with $E > 10^{16}$ eV requires, of course, the acceleration of particles to even higher energies. We have argued elsewhere[12] that shock-accelerated particles could not generate narrow γ-ray pulses at energies $E > 10^{14}$ eV. The basic point is that shock acceleration requires scattering, whereas the narrow pulses at the observed phases imply straight-line trajectories. Additional arguments rule out shock acceleration of electrons beyond ~10^{14} eV (ref. 12).

We now consider whether acceleration by a large amplitude Deutsch wave, as proposed by Gunn and Ostriker[13], could account for particles whose energy exceeds 10^{16} eV. The maximum energy that a particle with mass Am_p and charge Ze can attain by this mechanism is

$$E_{max} \simeq 6\times10^{14} A^{1/3} Z^{2/3} \times \left(\frac{B_{surf}}{10^{12}\,G}\right)^{2/3} \left(\frac{P}{10\,ms}\right)^{-4/3} \left[\ln\left(\frac{R_B}{R_L}\right)\right]^{2/3} \quad eV \quad (1)$$

where B_{surf} is the surface magnetic field, P is the pulsar's period, and R_L and R_B are the radii of the light cylinder and binary orbit, respectively. The luminosity in magnetic dipole radiation would be (magnetic moment assumed $\perp$ to $\vec{\Omega}$):

$$L_{MD} \simeq 6.5\times10^{40} \left(\frac{P}{10\,ms}\right)^{-4} \left(\frac{B_{surf}}{10^{12}\,G}\right)^{2} \quad erg\ s^{-1} \quad (2)$$

0028-0836/84/070613—02$01.00

© 1984 Macmillan Journals Ltd

so the maximum particle energy is given by

$$E_{max} \simeq 6.0\times10^{14}A^{1/3}Z^{2/3} \times\left(\frac{L_{MD}}{6.5\times10^{40}\ \mathrm{erg\ s^{-1}}}\right)^{1/3}\left(\ln\left(\frac{R_B}{R_N}\right)\right)^{2/3}\ \mathrm{eV} \qquad (3)$$

If the 10^{16} eV particles are electrons or positrons, then equation (3) implies that $L_{MD} > 2\times10^{46}$ erg s^{-1}, and the gravitational wave luminosity L_g ($\propto\Omega^6$), is even larger for any reasonable estimate of the quadrupole moment. However, the maximum rotational energy is $\sim10^{52}$ erg, and Cyg X-3 has been observed for over a decade with no obvious change in any of its behaviour, so the total luminosity must be $<10^{43}$ erg s^{-1}. This implies that particles accelerated to 10^{16} eV would have to be ions.

If ions are accelerated to $E > 10^{16}$ eV by a large amplitude Deutsch wave, the pulsar should be a strong source of gravitational radiation. Using equations (1) and (3) we find that if the accelerated ions are protons, the required period is $\sim3.7\,(B_{surf}/10^{12}\,\mathrm{G})^{1/2}$ ms and the corresponding magnetic dipole luminosity is $L_{MD} > 3\times10^{14}$ erg s^{-1}. Defining the quadrupole moment D as being equal to $q(6\times10^{41})\,(B_{surf}/10^{12}\,\mathrm{G})^2$, for easy comparison with Gunn and Ostriker[13], the spin-down rate due to gravitational radiation is $5q^2(B_{surf}/10^{12}\,\mathrm{G})^{-1}\times10^{-8}$ s^{-1}. Requiring the spin-down rate to be comfortably less than $(10\,\mathrm{yr})^{-1}$ limits q to less than $\sim0.25\ (B_{surf}/10^{12}\,\mathrm{G})^{-1}$. The corresponding gravitational wave luminosity would be $L_g \simeq 5\times10^{43}\,q^2(B_{surf}/10^{12}\,\mathrm{G})^{-1}$ erg s^{-1}, larger than that from the Crab pulsar by 5×10^5. This may be detectable, even without knowing the precise period, with a relatively low Q bar antenna. A young luminous pulsar in a close binary system like Cyg X-3 would probably drive a wind off the companion star that would enshroud the entire system; to this we attribute the lack of any detected pulses thus far. Indeed, X-ray observations[14] and radio observations[15] indicate that the system is embedded in optically thick material. In any case, the extreme youth of the pulsar required by the mechanism's production of 10^{16} eV ions could be considered an uncomfortably strong assumption.

An alternative view, which may be slightly less radical, is that the $>10^{16}$ eV particles are accelerated in the near zone along polar field lines where charge-separated zones can generate large potential drops[16–18]. A very liberal estimate of the maximum potential drop Φ_{max} is found by assuming that the entire polar zone is evacuated and the full vacuum potential is available[16]. In this case,

$$\Phi_{max} \simeq 7\times10^{16}\left(\frac{B_{surf}}{10^{12}\,\mathrm{G}}\right)\left(\frac{P}{10\ \mathrm{ms}}\right)^2\left(\frac{R}{10\ \mathrm{km}}\right)^3\ \mathrm{V} \qquad (4)$$

A pulsar in the Cyg X-3 system comparable to (perhaps slightly younger than) the Crab could account for 10^{16} eV particles if the full vacuum potential were available. However, near-zone acceleration requires that the particles be ions, as curvature radiation from electrons travelling along field lines (with radius of curvature R_c) limits the electron energy to

$$E_{max} \simeq 1.5\times10^{13}\left(\frac{P}{10\ \mathrm{ms}}\right)^{-1/4} \times\left(\frac{R_c}{10\ \mathrm{km}}\right)^{1/2}\left(\frac{B_{surf}}{10^{12}\,\mathrm{G}}\right)^{1/4}\ \mathrm{eV} \qquad (5)$$

Moreover, the UHE observations imply that pair production does not significantly short out electric fields in the near zone. Neither of these conclusions is expected from standard pulsar theory.

The possible detection[19,20] of $E > 10^{15}$ eV γ rays from the Crab could be explained as being curvature radiation from 10^{16} eV ions that are accelerated in the near zone. A better detection of this source—and similarly, the detection of a steady component of 10^{16} eV γ rays from Cyg X-3—would independently support the model of ion acceleration in the near zone. This would seem at present to be the least radical account of the 10^{16} eV γ rays that have been reported.

The more recent reports (ref. 21) of 10^{17} eV air showers from the direction of Cygnus cannot be accounted for by either of the pulsar mechanisms discussed here, when parameters that are consistent with a spin-down time >10 yr are used. If this directional excess is real and is found to have a 4.8-h period, more exotic models for particle acceleration in the Cyg X-3 system are required.

In conclusion, the detections of $>10^{15}$ eV γ rays from Cyg X-3 and their possible detection from the Crab have important implications for the theory of pulsars.

A simple non-markovian equation for a magnetoplasma

L. C. Woods

University of Oxford, Mathematical Institute, 24–29 St Giles, Oxford OX1 3LB, UK

A new kinetic equation for the velocity distribution function f is proposed here, with the innovation that the term $(\partial f/\partial t)_c$ representing the effect of particle collisions, incorporates time delays extending over the interval between successive 90° collisions. When this theory is applied to magnetoplasmas of the type found in tokamaks, it is found that the time delay has a dramatic effect on the heat flux across the magnetic field, giving results orders of magnitude larger than the classical values, and in fair agreement with observations. It appears that non-markovian effects are of great importance in magnetoplasmas, and that they provide answers to some unsolved problems in fusion research.

If $\mathbf{w}$ is the velocity of a cloud of particles at position $\mathbf{r}$, then the collision term in the kinetic equation for the one-particle phase-space density f,

$$\mathbb{D}f \equiv \frac{\partial f}{\partial t} + \mathbf{w}\cdot\frac{\partial f}{\partial \mathbf{r}} + \mathbf{F}\cdot\frac{\partial f}{\partial \mathbf{w}} = \left(\frac{\partial f}{\partial t}\right)_c \qquad (\mathbf{F} = \dot{\mathbf{w}}) \qquad (1)$$

may depend on the history of f. In general we should assume that it does, but Bogoliubov's[1] hypothesis permits us to ignore time delays in $(\partial f/\partial t)_c$, and while doubts are sometimes expressed, it is usually accepted that the timescale arguments that he devised for neutral gases also apply to fully ionized plasmas.

In a neutral gas the time τ_0 during which particles interact is very much shorter than the time interval τ between successive collisions. This means that the two-particle distribution function implicit in $(\partial f/\partial t)_c$ relaxes to its equilibrium state at a rate τ/τ_0 times more rapidly than f relaxes to its equilibrium state, namely

0028-0836/84/070614—02$01.00

the maxwellian distribution

$$f_0 = n\left(\frac{m}{2\pi kT}\right)^{3/2} e^{-u^2} \qquad \left(\mathbf{u} = \mathbf{c}/C,\ C^2 = \frac{2kT}{m}\right) \tag{2}$$

Here n is the number density, T is the temperature and $\mathbf{c}$ is the peculiar velocity, that is the difference between $\mathbf{w}$ and its average, $\bar{w} = \mathbf{v}$.

To take a simple example, the usual relaxation model for $(\partial f/\partial t)_c$ is

$$\left(\frac{\partial f}{\partial t}\right)_c = \tau^{-1}\{f_0(t) - f(t)\} \tag{3}$$

where f_0 and f are evaluated in the volume element $d\nu = d\mathbf{r}\, d\mathbf{w}$ of the cloud at the current instant. With this expression, equation (1) is 'markovian', that is, independent of the history of either f_0 or f. But $f_0(t)/\tau$ represents the rate at which particles are collided into $d\nu$ from the background plasma, and we should therefore give f_0 its value just prior to the interaction, at the same time preserving the essential irreversible character of $(\partial f/\partial t)_c$. Let irr $\{\ \}$ denote the irreversible part of $\{\ \}$, that is that part that has positive parity under time reversal; then equation (3) is replaced by

$$\left(\frac{\partial f}{\partial t}\right)_c = \text{irr}\,\{f_0(t-\tau_0) - f(t)\}/\tau \tag{4}$$

or

$$\left(\frac{\partial f}{\partial t}\right)_c \approx \tau^{-1}\{f_0(t) - f(t)\} + \frac{\tau_0^2}{2\tau}\mathbb{D}^2 f_0 \tag{5}$$

where the time derivative is evaluated at t, and $\mathbb{D}f_0$ has been omitted in the expansion, since it has the same parity as the left-hand side of equation (1), that is, it is reversible. (Strictly, equation (5) is markovian, since the history has been reduced to a current time derivative, but we shall regard it as non-markovian, to emphasize the distinction between it and equation (3).) With Bogoliubov's hypothesis,

$$\tau_0/\tau \ll 1 \tag{6}$$

equation (5) is reduced to equation (3), and the history of f_0 is thus discarded.

The long range of the Coulomb force throws considerable doubt on equation (6)[2]. A typical charged particle experiences a great number of small-angle collisions, interacting continuously with all of the $n_D = (4\pi/3)\lambda_D^3 n$ particles within a Debye distance, λ_D. The random component of these interactions accumulates over the 'collision' or kinetic time τ to deflect the particle through 90°. In this time the particle typically moves a distance $108\lambda_D n_D$ and hence interacts with $81 n_D^2$ particles. Thus in a typical laboratory plasma, a particle experiences $\sim 10^{13}$ grazing interactions per collision interval τ, which means that a 90° 'collision' is essentially a continuous process, lasting for the whole of the kinetic time τ. If we regard the encounter as occurring between a test particle P and the collection Q of particles within the Debye cylinder described above, or better, as a continuous binary encounter between P and a pseudo-particle Q, that lasts for most of the kinetic time τ, then in place of equation (6) we should write

$$\tau_0 = \alpha\tau \qquad (\alpha = 0(1)) \tag{7}$$

where α is a constant of order unity.

Provided the expansion

$$f_0(t-\tau_0) = -\tau_0\mathbb{D}f_0 + \tfrac{1}{2}\tau_0^2\mathbb{D}^2 f_0 \tag{8}$$

remains a good approximation for the somewhat longer τ_0 given by equation (7), equations (1) and (7) yield

$$\mathbb{D}f = \tau^{-1}(f_0 - f) + \tfrac{1}{2}\alpha^2\tau\mathbb{D}^2 f_0 \tag{9}$$

This is our simple, non-markovian kinetic equation. The principle involved here is simply that the equilibrium 'information' available in $d\nu$ is not the instantaneous value $f_0(t)$, but the value of f_0 about one relaxation time earlier, and the collisional processes tend to drive $f(t)$ irreversibly towards $f_0(t-\alpha\tau)$.

Of course, equation (9) is just a model equation, with a status similar to the relaxation model from which it was derived. But the two alternative non-markovian kinetic theories known to me[3,4] are so complicated that their consequences for mass and energy transport have not been pursued. At least equation (9) offers the chance of checking the importance of time delays in transport in a plasma, even if there remains some uncertainty in the value of the phenomenological constant α.

In a magnetic field, $\mathbf{B} = B\mathbf{b}$, particles with a charge q have a gyro frequency $\omega_c = qB/m$; we shall be concerned with 'strong' fields, that is, those for which $\omega_c\tau \gg 1$, which means that the cloud of particles in $d\nu$ gyrate about the field many times per 90° collision interval.

Transforming equation (9) from the laboratory frame in which the velocity $\mathbf{w}$ is measured, to a frame moving with the fluid velocity $\mathbf{v}$ and rotating with the local fluid angular velocity, $\boldsymbol{\Omega} = \frac{1}{2}\nabla\times\mathbf{v}$, we find (ref. 5)

$$\mathscr{D}f - \omega_c\mathbf{b}\times\mathbf{c}\cdot\frac{\partial f}{\partial\mathbf{c}} = \tau^{-1}(f_0 - f) + \tfrac{1}{2}\alpha^2\tau\mathscr{D}^2 f_0 \tag{10}$$

where

$$\mathscr{D} = D^* + \mathbf{c}\cdot\nabla + (\mathscr{F} - D\mathbf{v} - \mathbf{c}\cdot\boldsymbol{e}^s)\cdot\frac{\partial}{\partial\mathbf{c}} \tag{11}$$

$\boldsymbol{e}^s$ is the symmetrical part of $\nabla\mathbf{v}$, $D\mathbf{v}$ is the fluid acceleration, $\mathscr{F} = (q/m)(\mathbf{E} + \mathbf{v}\times\mathbf{B})$, $\mathbf{E}$ is the electric field and for scalars φ, vectors $\mathbf{a}$ and second-order symmetrical tensors $\boldsymbol{A}$, D^* is defined by

$$D^*\varphi = D\varphi, \qquad D^*\mathbf{a} = D\mathbf{a} - \boldsymbol{\Omega}\times\mathbf{a}, \qquad D^*\boldsymbol{A} = D\boldsymbol{A} - 2\boldsymbol{\Omega}\times\boldsymbol{A} \tag{12}$$

with

$$D = \frac{\partial}{\partial t} + \mathbf{v}\cdot\nabla \tag{13}$$

Thus D^* is a frame-indifferent time derivative.

In reducing $\mathbb{D}^2 f_0$ to $\mathscr{D}^2 f_0$, we have used equation (2), which gives $\mathbf{b}\times\mathbf{c}\cdot\partial f_0/\partial\mathbf{c} = 0$, and the fact that $\mathbb{D}^2 f_0$ must be evaluated with the coefficients of the derivatives held constant. Note that the rapid gyrations about the field lines have been excluded by changing from $\mathbb{D}$ to $\mathscr{D}$, so that now we require that equation (8) holds only for the operator $\mathscr{D}$ and on paths lying roughly parallel to $\mathbf{b}$.

The collision term on the right of equation (10) must conserve the number, momentum and energy of particles, so that

$$\int (1, m\mathbf{c}, \tfrac{1}{2}mc^2)\left(\frac{\partial f}{\partial t}\right)_c d\mathbf{c} = 0 \tag{14}$$

where the integral is over the whole of velocity space. To ensure this we are free to add to $(\partial f/\partial t)_c$ a complementary function $(\alpha_0 + \boldsymbol{\alpha}_1\mathbf{c} + \alpha_2 c^2)f_0$, where α_0, $\boldsymbol{\alpha}_1$, α_2 are functions of $\mathbf{r}$, t and independent of $\mathbf{c}$ (ref. 6). We do this later, using equation (14) to determine these parameters.

Let $\varphi \equiv (f - f_0)/f_0$ and assume $\varphi \ll 1$, then from equations (10) and (2)

$$\underset{(1)}{\varphi} - \underset{(2)}{\omega_c\tau\mathbf{b}\times\mathbf{c}\cdot\frac{\partial\varphi}{\partial\mathbf{c}}} = -\tau\mathscr{D}\ln f_0 + \tfrac{1}{2}\alpha^2\tau^2\{\mathscr{D}^2\ln f_0 + (\mathscr{D}\ln f_0)^2\} \tag{15}$$

where

$$\mathscr{D}\ln f_0 = (u^2 - \tfrac{5}{2})\mathbf{c}\cdot\nabla\ln T + 2\mathbf{uu}:\nabla^0\mathbf{v} \tag{16}$$

$\nabla^0\mathbf{v}$ being the traceless part of $\boldsymbol{e}^s$. We shall assume ∇T to be parallel to unit vector $\hat{\mathbf{r}}$ and perpendicular to $\mathbf{b}$. With $\omega_c\tau$ very large the term (1) in equation (15) yields a heat flux vector parallel to ∇T of the standard type[7],

$$\hat{\mathbf{r}}\cdot\mathbf{q}^{(1)} = -K_\perp\hat{\mathbf{r}}\cdot\nabla T \qquad (K_\perp \sim K_\parallel/(\omega_c\tau)^2) \tag{17}$$

where $K_\parallel$ is the thermal conductivity parallel to $\mathbf{b}$. On the other hand it is easily deduced from equation (16) (details will be published elsewhere) that the non-markovian term (2) in equation (15) gives

$$\hat{\mathbf{r}} \cdot \mathbf{q}^{(2)} = 7\alpha^2 \tau \frac{kp}{qB} H \hat{\mathbf{r}} \cdot \nabla T \qquad (H \equiv \mathbf{b} \times \hat{\mathbf{r}} \cdot \nabla^0 \mathbf{v} \cdot \hat{\mathbf{r}}) \quad (18)$$

The choice $\alpha = (2.5/7)^{1/2} \approx 0.6$ for the electron gas gives

$$\hat{\mathbf{r}} \cdot \mathbf{q}_e^{(2)} = -K_e^* \hat{\mathbf{r}} \cdot \nabla T_e \qquad \left(K_e^* \equiv \frac{5kp_e}{2eB} \tau_e H_e\right) \quad (19)$$

a result previously obtained[8] by quite different arguments. It was shown that in laboratory plasmas K_e^* is several hundred times larger than $K_{\perp e}$. Thus non-markovian effects are of great importance in the transport theory of a magnetoplasma. They may account for the relative failure of tokamaks and similar magnetoplasma machines to confine the plasma energy in the manner originally optimistically predicted by the standard theory. Provided τ_e in equation (19) is replaced by an average bounce time between the tokamak mirrors (good physical arguments can be advanced for this substitution), comparison of equation (19) with observations in tokamaks shows remarkably good agreement. Another interesting feature of equation (19) is that at sufficiently high densities H_e becomes negative and a thermal instability results that must disrupt the discharge; this may explain the well known disruptive instability in tokamaks[9].

To pursue these technical topics here would be inappropriate. The conclusion is that non-markovian effects are of great importance in a magnetoplasma, and that they appear to provide the answers to several unsolved problems in fusion research.

A possible mechanism for epeirogenic uplift

Dan McKenzie

Bullard Laboratories, Madingley Rise, Madingley Road, Cambridge CB3 0EZ, UK

Continental geology is dominated by vertical movements, some of these are the result of crustal shortening and extension associated with large horizontal displacements, involving processes which are now understood, at least in outline. However, both uplift and subsidence can occur without associated shortening or extension of the continental crust. Most investigations of such epeirogenic movements have been concerned with subsidence, partly because of the economic importance of the resulting sedimentary basins, and partly because of the existence of a simple model for the process[1] which can account for the development of several basins in some detail[2–4]. However, uplift has been relatively neglected and cannot be produced by the same mechanism. The purpose of this paper is to examine whether epeirogenic uplift can result from the intrusion of large thicknesses of basic magma into the lower part of continental crust. This suggestion was considered as a possible mechanism for the regional uplift of the Colorado Plateau by Gilbert[5] more than 100 years ago, and also by Holmes[6] (though both rejected the idea). However, a recent discussion of no less than 14 different mechanisms for generating uplift[7] did not include this process, even though it seems able to produce the observed vertical motions and also to account for some of the features of the evolution of sedimentary basins that cannot be explained by the uniform stretching model[3,8,9]. Although the suggestion is not new, the argument used here to support it is, and depends on an understanding of the relationship between ocean island volcanoes and mantle circulation.

In the ocean basins magma is generated in two different environments. Plate separation at ridges leads to adiabatic upwelling and melting. This process produces most of the oceanic crust. The other type of feature which produces magma in the ocean basins is intra-plate volcanism such as that which is occurring in Hawaii, Iceland and the Azores. No detailed estimates of the volume of volcanic material produced by intra-plate volcanism appear to have been made. Ben-Avraham *et al.*[10] suggest that about 10% of the ocean floor is covered by aseismic plateaux, almost all of which are volcanic constructs. The crustal thickness beneath these features is about 20 km, of which perhaps 15 km has been added to the normal oceanic crustal thickness by volcanism. The error in the estimate of the total volume involved may be as much as a factor of two; more accurate estimates are not critical to the present argument. Many of the major ocean island volcanoes which are now active are believed to be at the centre of hot rising regions within the mantle[11–13]. Although the nature of the relationship between the magma and the upwelling is not yet clear, it is generally agreed to exist. The importance of this association is that hot rising regions are generated at the base of the convecting region[11] by instabilities of the lower thermal boundary layer. The distribution of these regions, and hence the rate of magma production from such sources, should therefore be independent of the distribution of continental and oceanic lithosphere, though they cannot yet be mapped beneath the continents by the methods used in the oceans. Many authors have proposed continental volcanoes which they believe to be the surface expression of such rising regions. Certainly some of these volcanoes are likely to have such an origin. There is a major difficulty to be overcome, however, if the rate of magma production in the rising regions is to be the same beneath both continents and oceans. The mean age of oceanic lithosphere is no more than 100 Myr, whereas that of the continental lithosphere is probably at least 1,500 Myr. Hence 15 times more of the continent than of the ocean should be covered by a basaltic layer 15 km thick. Such basalt should therefore make up about 75% of the continental crust of 30 km thickness. Compared with this estimate the volume of flood basalts even in an area such as the Deccan is negligible. Clearly this argument is not compatible with geological observations if the magma is erupted at the surface.

The geological observations are, however, not contradicted if this volume of magma is injected into the lower half of the continental crust. The mean density of the continental crust is about 2.8 Mg m^{-3} (ref. 14), and varies from about 2.6 Mg m^{-3} at the top to 3 Mg m^{-3} at the bottom. The composition of the intruding magma has little effect on its density, which is likely to be between 2.7 and 2.9 Mg m^{-3} (ref. 15) at a depth of 30 km. If much of the primary magma is picritic, as seems likely[16,17], its density will be at the upper end of this range. Therefore, whatever its composition, such a magma could form sills within the plate. This emplacement is likely to be within the crust if the magma density is less than that of the lower crust, or it could form a layer between the crust and the mantle if its density is greater. If the whole of the lower part of the continental crust is produced in this way, the resulting velocity of P waves should be between 6.8 and 7.0 km s^{-1}, in agreement with that observed. Cox[17] has proposed a similar model on petrological grounds, and argued that differentiation within a picritic layer could generate plateau basalts. Large intrusions of basic magma could also provide the source of heat required to generate rhyolites and granites from the continental crust by anataxis[18–20], and in this way satisfy the isotope constraints[21–23]. Such intrusions into

0028–0836/84/070616—03$01.00

© 1984 Macmillan Journals Ltd

the lower crust could account for the horizontal layering seen in many deep reflection profiles of the continental crust (refs 24, 25 and D. H. Matthews, personal communication). Clear reflections from the Moho also suggest that extensive intrusion of dykes is not common. The resulting uplift, followed by erosion, can explain the dominance of high grade metamorphic rocks in the surface outcrop of Archaean terrains[26].

Perhaps the most important consequence of the intrusion of great thicknesses of magma into the lower crust is the associated surface uplift. The addition of 15 km of material of density 2.7 Mg m^{-3} to the crust which overlies mantle of density 3.3 Mg m^{-3} produces 2.7 km of permanent uplift, sufficient to generate features like the Colorado Plateau. The reason Gilbert[5] argued against such a mechanism is that the plateau is bounded by linear monoclines, whereas the smaller intrusions he mapped in the Henry Mountains were circular in plan. However, it would not be surprising if the uplift reactivated old lines of weakness in the upper crust as faults that may underlie the monoclines. Gilbert's objection does not therefore seem to be fundamental. Some uplifted regions, such as Lesotho in southern Africa[27], have probably existed for longer than 60 Myr, the thermal time constant of the lithosphere. This region is also more than 100 km from the continental margin. Such uplift is therefore unlikely to be produced by lithospheric heating[28], which would not extend more than about 100 km from the margin and would decay with a time constant of 60 Myr. There is, however, no difficulty in producing the uplift by large intrusions, and the resulting elevation can only be removed by erosion. Furthermore, many uplifted regions are associated with extensive surface volcanism.

These arguments therefore suggest that large igneous intrusions are a major cause of uplift. Another cause is likely to be the uplift produced by the hot upwelling mantle. In oceanic regions such uplift has a scale of 1,000 km or more, and an amplitude of about 1 km. Similar surface deformation should exist in continental regions, although the subaerial amplitude will be reduced to about 700 m. Such features should be widespread, though their existence has not been clearly established. Unlike uplift produced by crustal thickening, that resulting from mantle upwelling will disappear as the plate moves away from the rising region. Also, the horizontal scale of the uplift produced by mantle upwelling should be greater than that from igneous intrusion. The source of the magma may be the hot upwelling region, especially in regions remote from plate boundaries. This is the only source whose production rate can be estimated. Near plate boundaries basic magma is generated in other ways, by both extension and subduction, and may also be emplaced into continental crust.

The above discussion has been concerned with uplift which is not directly associated with crustal shortening or extension. It is likely that some major igneous intrusions into the lower crust also occur in continental regions undergoing deformation. If such additions occur during the extension associated with the formation of a sedimentary basin, the volume of the crust will not be conserved. This process has been discussed by several authors[9,29], all of whom required that there be a relationship between the extension and the amount of melt produced. No such relationship is, in general, to be expected unless both the temperature and composition of the mantle are constant. The ratio of the final to the initial area, β, cannot then be estimated from the change in crustal thickness. Since the density of the intrusion is similar to the mean crustal density ρ_c, the initial tectonic subsidence, s_i, is approximately related to the initial, t_c, and final, t_f, crustal thicknesses by

$$s_i = \frac{(\rho_m - \rho_c)(t_c - t_f)}{(\rho_m - r_w)} \quad (1)$$

where $t_c > t_f$, ρ_m is the density of the mantle, ρ_w that of seawater and the upper surface of the crust is initially at or below sea level. The final thickness t_f then consists of the sum of the thickness t_c/β of original crust and of that, t_I, of intrusions (Fig. 1). The igneous material will probably not be emplaced as dykes but as sills, because the density of most magma types exceeds that of upper crustal material. After the extension ceases, the thermal subsidence and heat flux will be controlled by the extension of the lithosphere, which will exceed that (β_a) estimated from the change in crustal thickness. The heat flux associated with the intrusion itself will decay quickly, because the thermal time constant of a 30 km thick layer is less than 5 Myr.

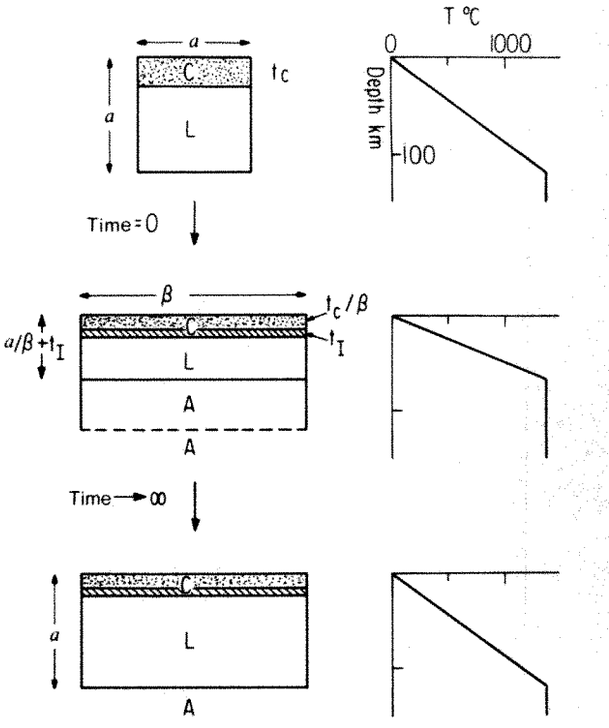

Fig. 1 A piece of thermally equilibrated continental lithosphere of thickness a, consisting of crust C (dotted) and mantle L, underlain by asthenosphere A, is uniformly extended by a factor β at time 0, and a thickness t_I of basic magma (cross-hatched) is added to the crust. The total change in thickness of the continental crust, marked C, is $t_c(1-1/\beta)-t_I$ and controls the tectonic subsidence associated with faulting during the stretching event. In contrast, the variation of temperature with depth is controlled by β, as are also the heat flux and the thermal subsidence. In the example illustrated $\beta = 2$ and $t_I = 7.5$ km. Hence the value of β obtained from the change in crustal thickness would be 1.33.

The effects of extension combined with large additions to the crust therefore closely resemble those which Royden and Keen[8] and Royden *et al.*[3] have argued should be produced by stretching the mantle part of the lithosphere more than the crust. The behaviour of the model proposed above is the same as that of Royden *et al.* if their crustal value of β, β_a, is defined to be

$$\beta_a = t_c/(t_I + t_c/\beta) \quad (2)$$

The value of β_a controls the change in crustal thickness and initial subsidence, whereas the true value of β controls the heat flux and thermal subsidence. In regions such as the Pannonian Basin the magma is more likely to be produced by the subduction zone than by the hot rising jet within the mantle.

Despite the similarity in the behaviour of the model proposed here to that of Royden *et al.*[3], the physical processes involved are rather different. If the crust is everywhere stretched less than the mantle part of the lithosphere, as they suggest, a space problem arises. If, however, the true crustal extension is the same as that of the mantle, but merely appears to be less because crustal volume has not been conserved, there is no such difficulty. In the Pannonian Basin the thermal subsidence requires a value

of β of at least 3, whereas the present crustal thickness and the initial subsidence suggest a value of β of about 2. If the initial crustal thickness was 36 km, these values require the addition of 6 km or more of igneous material. Such a thickness is not unreasonable, as large amounts of volcanic material were being erupted in the surrounding regions during the extensional event, probably generated by a subduction zone. Whether the large horizontal displacements, which must occur if β is to have a value of more than 3, can be accommodated by faulting is uncertain. Though this objection has been raised repeatedly[30,31] against the stretching model even in the absence of additions to the crust, the accuracy of estimates made from fault geometry is still controversial[32]. In contrast to the Pannonian Basin, little volcanism was associated with the extension of the North Sea, and therefore different methods of estimating β yield similar values[4].

Massive intrusions can also occur in regions undergoing shortening, where they will add to the uplift produced by crustal thickening.

I thank K. Cox, L. Royden, K. O'Nions and R. Wood for helpful comments, and NERC and the University of Chicago for support. Department of Earth Sciences contribution 494.

Isotopic and geochemical evidence for the evolution of a cyclic unit in the Rhum intrusion, north-west Scotland

Z. A. Palacz*

Department of Earth Sciences, The University, Leeds LS2 9JT, UK

Layered basic intrusions can record processes which operated within basic magma chambers. In particular processes such as magma mixing and fractionation can be identified from the chemistry of cumulus minerals. Isotopes have been used to identify contamination in lavas[1–6], but they can also be applied to cumulates to infer a continuous record of the interactions of crust and magma within the magma chamber. We report here that olivine compositions, rare earth elements (REE) on mineral separates and Sr isotopes on whole rocks and pyroxenes from unit 9 of the Eastern Layered Series of the Tertiary Rhum intrusion, north-west Scotland, suggest that fresh magma entered the chamber and mixed with fractionated and contaminated magmas at the base of the chamber. With prolonged residence in the chamber the fresh magma became fractionated and contaminated, was then erupted off and replaced by fresh magma which produced the basal peridotites of unit 10.

The Eastern Layered Series (ELS) comprises 15 cyclic units[7], each representing the crystallized products of successive injections of magma into the chamber[7,8]. A typical sequence of rocks within a cyclic unit comprises peridotite, grading upwards into troctolite and finally gabbro, corresponding to the first appearance of olivine, plagioclase and the clinopyroxene on the liquidus with decreasing temperature. The basal peridotites are in sharp contact with the gabbros of the preceding unit.

Unit 9 is 21 m thick (Fig. 1), olivine being the only cumulus mineral present throughout the unit. The forsterite content can be directly related to the Mg/Mg+Fe(II)) ratio of the magma (an index of fractionation)[9].

The most Mg-rich olivines would be expected at the base and the most Fe-rich olivines at the top of the unit. In unit 9 the olivines are more Mg rich upsequence through the peridotites (Fig. 2, Table 1). Within the troctolites the compositions vary, while the olivines within the gabbros become more Fe-rich, particularly towards the top of the unit. The base of unit 10 has more Mg-rich olivines than the top of unit 9. This would, perhaps, be consistent with the eruption of fractionated magma and replacement by fresh magma.

In contrast, the olivines in the gabbros at the top of unit 8 have almost identical compositions with those in the basal peridotite of unit 9, while olivines 2 m below the unit 8/9 contact (41597) are the most evolved yet found in the ELS. The basal peridotite (42142) of unit 9 contains a unique occurrence of cumulus clinopyroxene, restricted to the basal metre of unit 9. They form up to 15% of the mode and are small subhedral crystals occasionally enclosed within cumulus olivine, but more typically within intercumulus pyroxene and plagioclase. They are unzoned with compositions comparable with the cumulus pyroxenes in the gabbros at the top of unit 8.

The approximate equivalence of olivine and pyroxene compositions across unit contacts (Table 1) and the progressively more primitive nature of olivines upsequence through the peridotites has been interpreted as being due to magma mixing[10] between a fractionated magma and a fresh magma batch. The presence of cumulus pyroxenes at the base of unit 9 may support this.

Sr isotopes measured on whole rocks and pyroxene separates are presented in Fig. 2 and Table 1. Rb/Sr measurements on several samples indicate that the age correction (60 Myr) is insignificant and within experimental error, therefore ratios where no Rb data are available are assumed to be initial ratios. The variations in $^{87}Sr/^{86}Sr$ through unit 9 are large.

Clinopyroxenes through unit 9 are generally in isotopic equilibrium with the whole rocks. The only exceptions are at the tops of units 8 and 9. Disequilibrium between pyroxene and magma can be caused by magma mixing between two or more isotopically distinct magmas with the pyroxenes being derived from one magma[11]. Because the rate of Sr diffusion in pyroxene is slow compared with that in the magma[12], it is possible for the pyroxene to retain the $^{87}Sr/^{86}Sr$ of the magmas it originally crystallized from and not reequilibrate with the magma it settled in. Pyroxenes are also resistant to hydrothermal alteration[13]. Because the pyroxenes were leached[14], any hydrothermal Sr will be removed, therefore because pyroxenes and whole rock $^{87}Sr/^{86}Sr$ are equivalent these variations are considered primary and not the result of hydrothermal alteration.

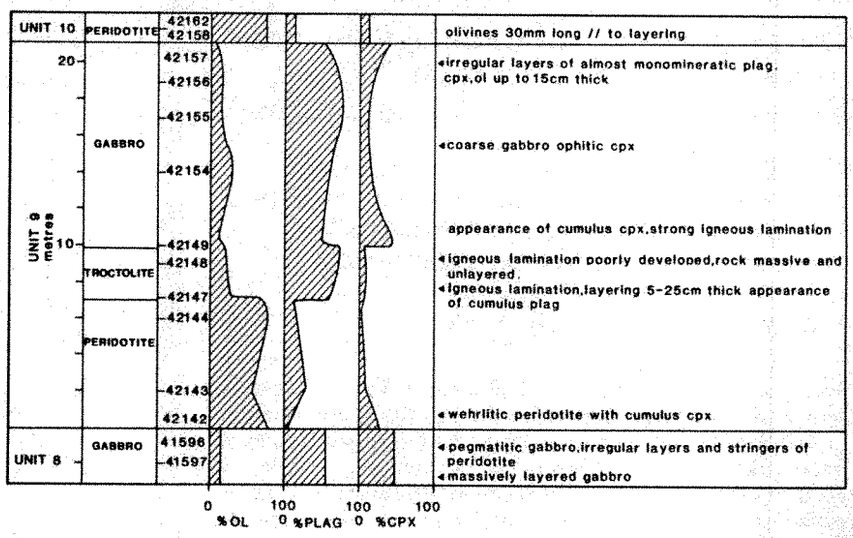

Fig. 1 Lithological log through unit 9.

The unit can be divided isotopically into two. In the peridotites $^{87}Sr/^{86}Sr$ is ~0.705, while the gabbros are mainly ~0.704. The troctolites appear to have transitional values. Within the gabbros an increase in $^{87}Sr/^{86}Sr$ at the top of unit 9 coincides with Fe enrichment in olivine and may represent the process of combined assimilation of high $^{87}Sr/^{86}Sr$ crust and fractional crystallization (AFC)[3]. A sharp reduction in $^{87}Sr/^{86}Sr$ at the base of unit 10 coincides with more Mg olivines which may suggest that contaminated and fractionated magmas were erupted off and replaced by relatively uncontaminated and unfractionated magmas.

In the peridotites of unit 9 a more complex situation is present. The olivine compositions indicate that magma mixing has operated. The Sr isotopes may support this because the $^{87}Sr/^{86}Sr$ of the peridotites is substantially higher than the basal peridotites of unit 10 and may represent a mixture of high $^{87}Sr/^{86}Sr$ magma which crystallized the top gabbro of unit 8 and low $^{87}Sr/^{86}Sr$ fresh magma.

The REE contents of separated pyroxenes are presented in

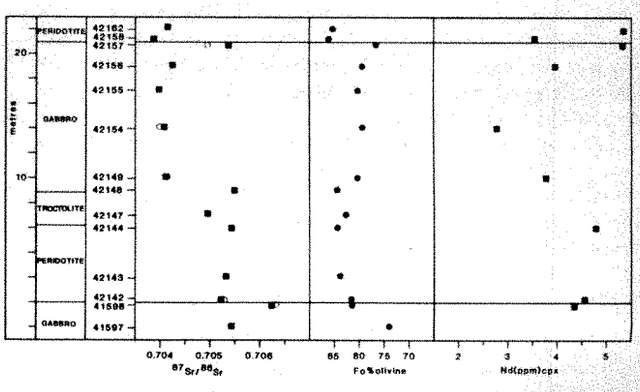

Fig. 2 Variation in whole rock (squares) and clinopyroxene (circles) $^{87}Sr/^{86}Sr$ through unit 9, compared with Fe content in olivine and Nd concentration in clinopyroxene.

42142 CPX	—	3.78	4.57	1.75	0.56	2.29	—	1.29	0.97
41596 CPX	0.77	3.26	4.360	1.65	0.52	2.03	—	1.19	0.94

From ref. 15. Errors 2 s.e. are 1%. CPX, clinopyroxene.

Table 2. The REE patterns are parallel, with variable, small, negative Eu anomalies. Because the patterns are parallel the total REE content ($\sum$ REE) of the pyroxenes can be expressed in terms of one element, Nd, for example. The variation of Nd through unit 9 (Fig. 2) is remarkably similar to $^{87}Sr/^{86}Sr$. Although Nd can increase in magma during fractionation, $^{87}Sr/^{86}Sr$ cannot, consequently, these variations represent the addition of a high Nd, high $^{87}Sr/^{86}Sr$ contaminant. This addition is seen in the gabbros at the top of unit 9 and coincides with fractionation. The peridotites of unit 9 also seem to be contaminated. However, this contamination could be the result of magma mixing between the fresh magma influx and any contaminated magma left in the chamber.

I thank Drs M. F. Thirlwall, R. A. Cliff and B. M. Wilson for helpful discussion and criticism and Dr E. Condliffe for advice on the microprobe. Isotope work at Leeds is funded by the Royal Society and NERC, and this work was performed during the tenure of a NERC studentship.

Oxygen isotope calibration of the onset of ice-rafting and history of glaciation in the North Atlantic region

N. J. Shackleton*, J. Backman, H. Zimmerman, D. V. Kent, M. A. Hall, D. G. Roberts, D. Schnitker, J. G. Baldauf, A. Desprairies, R. Homrighausen, P. Huddlestun, J. B. Keene, A. J. Kaltenback, K. A. O. Krumsiek, A. C. Morton, J. W. Murray & J. Westberg-Smith

We report here that DSDP Site 552A, cored with the hydraulic piston corer on the west flank of Rockall Bank, recovered an undisturbed sequence of alternating white deep-sea carbonate oozes and dark-coloured layers that are rich in glacial debris. Oxygen isotope analysis of the sequence together with detailed nannofossil and palaeomagnetic stratigraphy shows that the first major horizon of ice-rafting occurred at about 2.4 Myr, and was preceded by a minor pulse of ice-rafting at about 2.5 Myr. The carbon isotope record shows that the site has been bathed by a water mass of similar characteristics to present-day North Atlantic deep water at least since 3.5 Myr.

Despite the concentration of members of the deep-sea drilling community around the North Atlantic, surprisingly few Deep Sea Drilling Project sites have been drilled that are suitable for even a cursory study of North Atlantic palaeoenvironments. Until recently the best sites in which to study the onset of glaciation around the North Atlantic were from DSDP Leg 12, sites 111 and 116, in which Berggren[1] studied the stratigraphic position of the earliest ice-rafted debris in the region and estimated its age at 3.0 Myr (Backman[2] re-examined this material and obtained a younger estimate of 2.5 Myr). Sediments from the Leg 12 sites were extensively disturbed by rotary drilling, and not suitable for detailed analysis of the palaeoenvironmental record. During Leg 81, the *Glomar Challenger* used the newly developed hydraulic piston corer (HPC)[3] with considerable success, and in particular recovered a section from the west flank of Rockall Bank (Fig. 1) that is largely undisturbed.

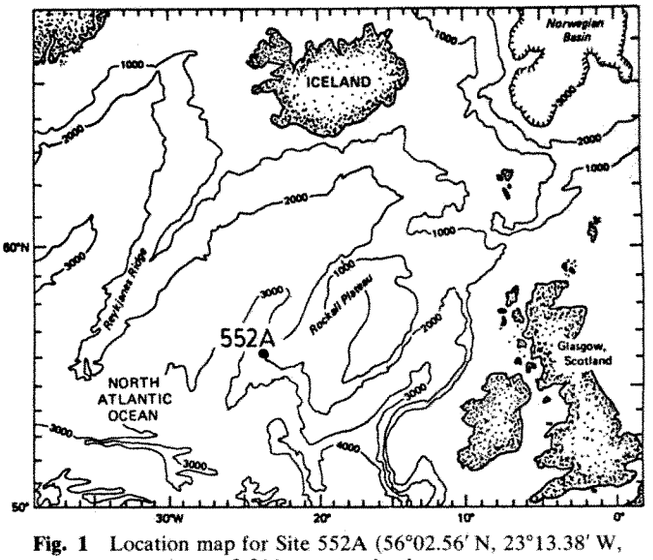

Fig. 1 Location map for Site 552A (56°02.56′ N, 23°13.38′ W, 2,311 m water depth.

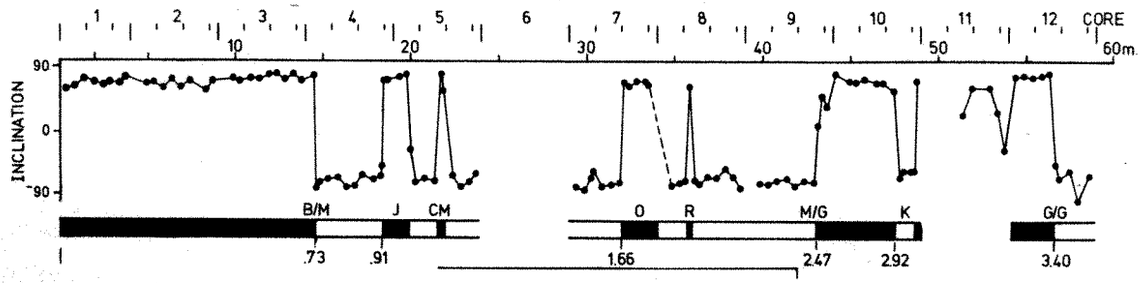

Fig. 2 Magnetic record for Site 552A. Demagnetized inclinations are shown only for apparently undisturbed parts of the cores (the data from core 11 suggest that some unrecognized disturbance may be present).

The upper 40 m of the section comprises alternating units of white and dark grey colour. In the white intervals, the >150-μm fraction consists almost exclusively of foraminifera; in the dark intervals angular sand-sized rock fragments predominate although sufficient benthic foraminifera for isotopic analysis are present at almost every horizon examined. The dark-coloured intervals containing ice-rafted material are visually clear and also show unmistakably in a record of carbonate content (typically between 80 and 90% in the white layers and 10–40% in the dark layers).

We have made isotope analyses at 10-cm intervals over the interval from well below the first ice-rafting layer, through to the recent sediment. Only core 6 was excluded from analysis because it was very severely disturbed by coring. Three species were used: *Globocassidulina subglobosa*, *Uvigerina peregrina* and *Planulina wuellerstorfi*. In Figs 3 and 4 data are presented using the previously established 'correction factors' to relate the oxygen isotope values obtained for *G. subglobosa* and *P. wuellerstorfi* to the equilibrium value which is thought to be given by *Uvigerina* spp.[4,5]. Carbon isotope values are related to *P. wuellerstorfi* rather than to *Uvigerina* because this procedure provides a good estimate of the ^{13}C content of ocean dissolved CO_2 (refs 6, 7).

Samples for palaeomagnetic analysis were taken approximately every 25 cm, avoiding sediment that showed any sign of disturbance. Only orientation with respect to the vertical axis was preserved so that the inclination component is used to infer polarity at this high-latitude site. The natural remanent magnetization (NRM) was measured on a two-axis cryogenic magnetometer[8] both before and after alternating-field demagnetization at 10–30 mT. NRM intensities are typically of the order 10^{-2} A m^{-1} in the upper 45 m of the section, decreasing to about 10^{-3} A m^{-1} in the lower part. Measured inclination data are shown in Fig. 2. Inclinations are generally well-grouped near to the expected dipole value (71°, positive for normal and negative for reversed) for the latitude of the site, indicating that a reliable record of the geomagnetic field has been obtained to the base of the Gauss normal magnetochron. The lower boundary of the Olduvai subchron is unfortunately obscured by disturbance at the break between successive cores, while the Mammoth subchron is unclear, probably lying in a slightly disturbed section of core 11.

Analyses of the carbonate content of the sediment have also been made at 10-cm intervals through the upper 59 m of the section. In this part of the North Atlantic, carbonate content is controlled chiefly by variations in the influx of non-carbonate material transported by ice[9]. Changing carbonate production also has a major role, while carbonate dissolution has little impact at such shallow water depths in the North Atlantic.

The samples taken for stable isotope analysis were also used for quantitative nannofossil studies; here we show (Fig. 4) only those nannofossil data which have a bearing on the biostratigraphical position of the early ice-rafting horizon.

Figure 3 shows the oxygen isotope and carbonate data for the upper five cores, together with the oxygen isotope record of core V28-238 (ref. 4) for comparison. Both records are plotted linearly with respect to depth in sediment between magnetic reversals. Since it has been established that the sediment in V28-238 accumulated at a fairly regular rate[10], the axis

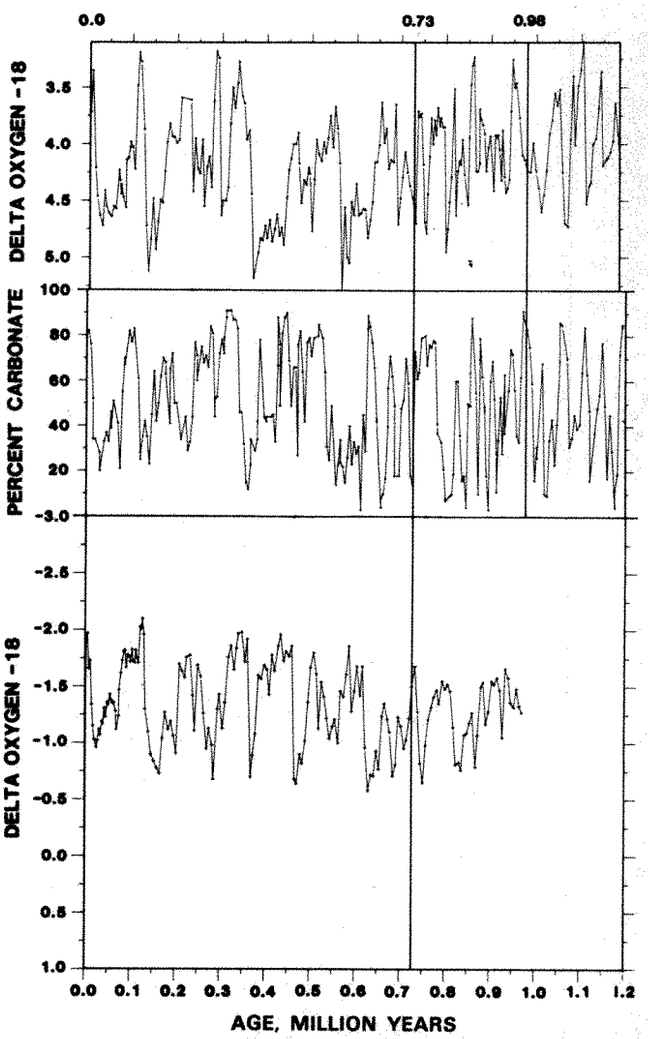

Fig. 3 Top: Oxygen isotope record of Site 552A cores 1–5. The plotting scale is linear between magnetic reversal horizons. Middle: carbonate content in the same interval; low carbonate content implies dilution by ice-rafted material. Bottom: oxygen isotope record of Pacific core V28-238 (ref. 4) for comparison. Vertical lines indicate the horizons used for time control: top (zero age), base Bruhnes normal chron (0.73 Myr), base Jaramillo subchron (0.98 Myr).

is shown as an approximate age scale calibrated on the basis of the single magnetic reversal in this core. Thus the comparison shows that there have been quite marked accumulation rate variations in DSDP 552A. This is hardly surprising in view of the lithological variations that are evident. Nonetheless the oxygen isotope record of Site 552A is complete to the extent of preserving every isotope stage.

In Figure 4, the oxygen isotope data for the lower part of the sequence are shown and compared with the oxygen isotope data for piston core V28-179. (Figure 4 shows additional measurements that we have made in core V28-179. Note that the position

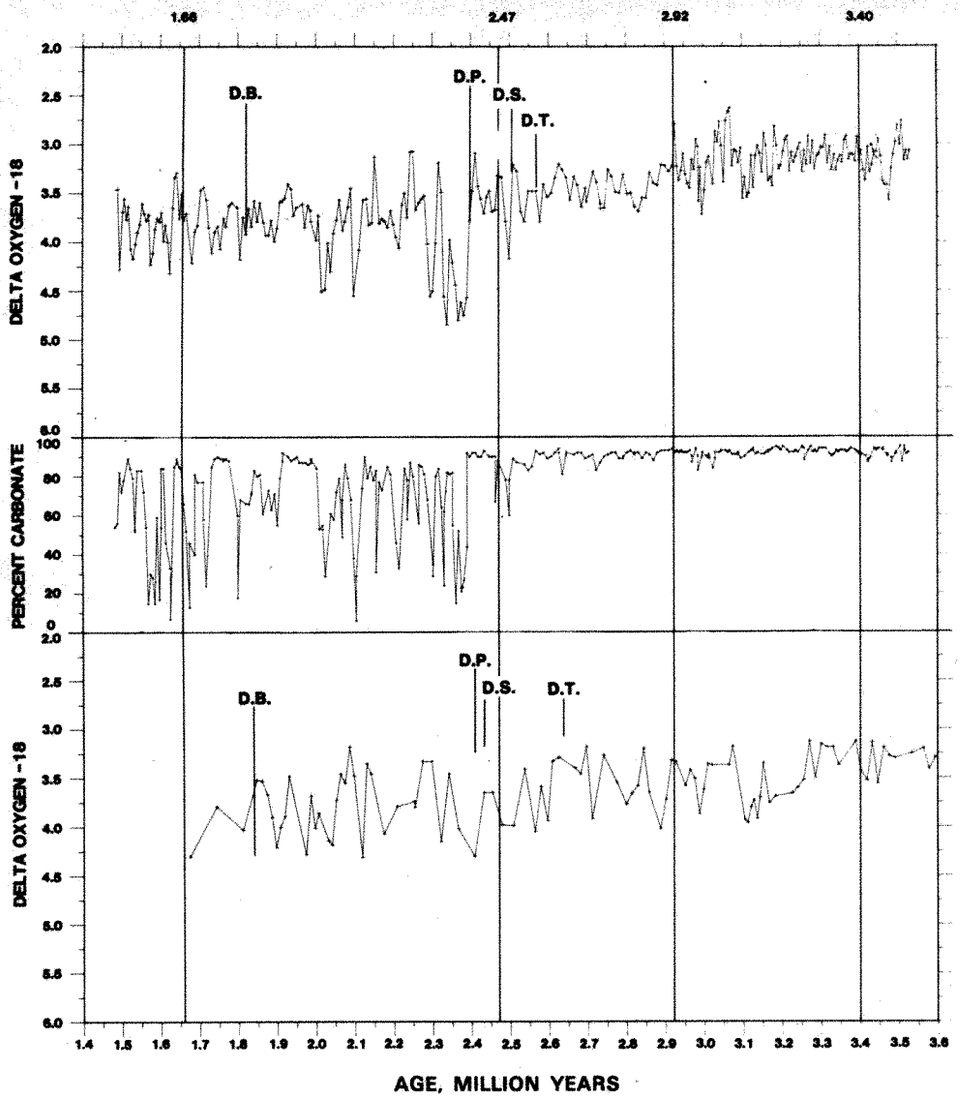

Fig. 4 Top: Oxygen isotope record of Site 552A cores 7–12. The plotting scale is linear between magnetic reversal horizons. Middle: carbonate content in same interval. Bottom: oxygen isotope record in Pacific core V28-179 (ref. 11) for comparison. Vertical lines show horizons used for time control: top Olduvai normal subchron (1.66 Myr), base Matuyama reversed chron (2.47 Myr), top Kaena reversed subchron (2.92 Myr), base Gauss normal chron (3.40 Myr). Nannofossil extinction horizons determined in both cores indicated by: DT, *Discoaster tamalis*; DS, *D. surculus*; DP, *D. pentaradiatus*; DB, *D. brouweri.*

of the Gauss–Matuyama boundary was incorrectly printed in ref. 11; it was in fact located at 1,338 cm, not 1,358 cm.) Again, to facilitate comparison, the plotting scale for both records has been adjusted at magnetostratigraphic boundaries as indicated, so as to approximate an age scale using a palaeomagnetic time scale[12]. Obviously the application of this age scale becomes less accurate far from the magnetic reversals. However, comparison between the two records is good considering the low accumulation rate, and relatively coarse sampling interval in V28-179, and many small-scale features can be correlated between the two. The amplitude of variation is substantially greater in Site 552A than in V28-179. This is probably due to the effect of bioturbation in the Pacific core; since the accumulation rate of core V28-179 was only about 0.55 cm kyr^{-1}, one would expect climatic extremes lasting only a few thousand years to be severely degraded by bioturbation.

The series of nannofossil extinction data shown in Fig. 4 have also been determined quantitatively in core V28-179 (ref. 13) and their ages estimated. Using these estimates, the average accumulation rate over the pre-ice-rafting interval in Site 552A may be estimated at approximately 1.7 cm kyr^{-1}, surprisingly close to the average for the upper part, 1.8 cm kyr^{-1} (although the rate has certainly varied over short intervals during the intense climatic fluctuations of the past few million years). Palaeomagnetic stratigraphy and nannofossil stratigraphy in this site give identical estimates for the age of the first major northern hemisphere glacial event about 2.37 Myr.

It is clear from an examination of Figs 3 and 4 that there is a remarkable correspondence between the records of oxygen isotopic composition in the foraminifera, and carbonate content, back to about 2.4 Myr. This is not particularly surprising since both are clearly causally related to glaciation. However, it is worth noting that if the late Pliocene isotopic fluctuations were attributed to glaciation in Antarctica, one would not expect the influx of ice-rafted debris during the glaciation at 2.4 Myr to be as dramatic as that observed in the last glacial, whereas this is what we observe in Site 552A. A brief ice-rafting episode, coinciding with positive ^{18}O values, is observed at about 2.5 Myr. Prior to 2.5 Myr, the influx of ice-rafted debris is minute and has little impact on the record of carbonate content. Presumably such glaciation as may have occurred before that time did not give rise to extensive calving of icebergs into the North Atlantic.

If we compare the isotopic composition of benthonic foraminifera at the level of the first glacial maximum at 2.37 Myr with values in glacial levels in the upper part of the sequence, it becomes apparent that the early event represents a truly glacial interval, with an ice volume similar to maxima during the middle Pleistocene. This must, for instance, be correlative with a fully glacial environment in Britain although obviously the actual ice-margin positions cannot be determined from these data.

Other data relating to a major climatic threshold being crossed at this time comes from the Netherlands and New Zealand. In the Netherlands, Zagwijn[14] has shown that there was a complete

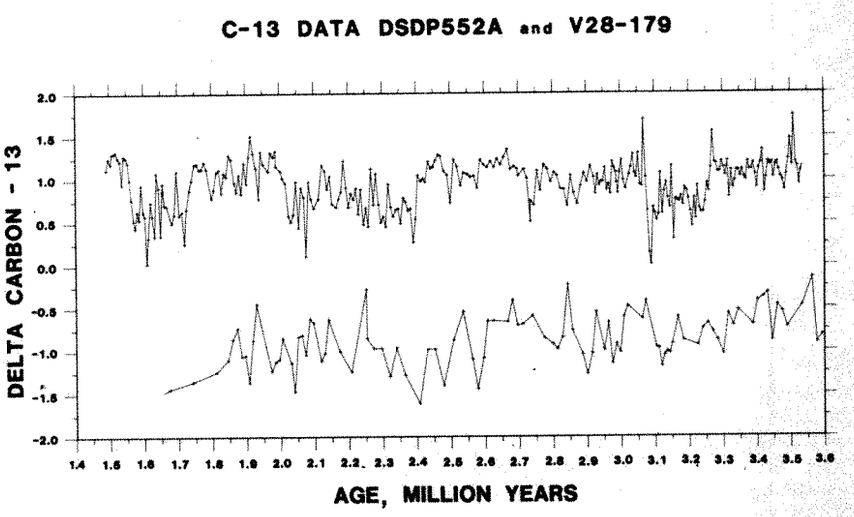

Fig. 5 Carbon isotope records for Site 552A cores 7–12 (top) and Pacific core V28-179 (bottom). Both are plotted on the same ^{13}C scale and represent estimates of the ^{13}C contents of intermediate depth (2,311 m) water in the North Atlantic (above) and of deep (4,509 m) water in the equatorial Pacific (below). Today there is an observed difference of a little over 1‰ which reflects the fact that ocean deep waters are ventilated in the North Atlantic.

overturn in vegetational type just after the Gauss–Matuyama boundary; indeed he regards this as representing the Pliocene–Pleistocene boundary. In New Zealand, Stipp and others[15] showed that there was a major drop in sea level between about 2.4 and 2.6 Myr; again, they correlated this event, which they interpreted as the first glacio-eustatic fall in sea level, with the Pliocene–Pleistocene boundary. We disagree with these opinions, only because we consider it well established that the Pliocene–Pleistocene boundary at the newly proposed stratotype at Vrica[16], as well as at previous Calabrian sections, has a much younger age of about 1.6 Myr (ref. 17). If the boundary were selected on the basis of a significant climatic event rather than on historical precedent, it might appropriately be re-positioned so as to coincide with the climatic change about 2.4 Myr, but we do not recommend such an approach to the definition of geological boundaries.

The data shown in Fig. 4 also indicate that there was considerable climatic variability, somewhere on the globe, even before 2.5 Myr. It is well established that glaciation in Iceland occurred as early as 3.1 Myr (ref. 18) although recent work suggests that glaciation did not reach sea level in Iceland until about 2.0 Myr (ref. 19) and there is also evidence for glaciation in the Sierra Nevada, California, at about the same time[20]. However, palaeooceanographic conditions on Rockall Bank do not suggest severe climates in North-west Europe. Occasional grains of ice-rafted debris do occur, and the nannofossil floras certainly show marked variation, but the scale of variation was much less before 2.4 Myr than it was after the event at that time.

Figure 5 shows the carbon isotope records for DSDP 552A and V28-179. The data are plotted on the same isotope scale and the same species-dependent correction factors have been made to both. The persistent isotopic difference between the two records of over 1‰ indicates a continuing situation in which the water bathing the sea floor on Rockall was isotopically heavier for ^{13}C than deep water in the Pacific, as is the case today. This difference reflects the difference between newly-formed, oxygen rich North Atlantic deep water (NADW) and older, oxygen-depleted deep Pacific water[21,22]. We (and also Blanc *et al.*[23]) disagree with Keigwin's deduction[24] that the formation of NADW only began with the closing of the Panama Straits at 3.0 Myr, although this event may well have affected the contribution that this water mass made to the deep water of the Caribbean deep waters that were the topic of Keigwin's study[24].

In the upper part of the section, it is clear that DSDP Site 552A preserves the whole of the standard oxygen isotope record of the past million years. Although the fine structure of many stages is obscure, every single stage is present. By comparison, we note that the stratigraphically longest piston core from the North Atlantic, core Kane 708-7 (ref. 9), extends only to Stage 17 at about 0.6 Myr. For the earlier record, only DSDP Site 116, recently re-investigated from the palaeoclimatic point of view[25], was previously available. Site 116 was recovered by conventional rotary drilling and the sediment was so disturbed that glacial and non-glacial materials are intermixed, precluding any high-resolution studies being made. It is to be hoped that the new technique of ^{13}C analysis in the organic carbon portion of the sediment, pioneered in Site 116 (ref. 25), will be applied to Site 552A. We believe that the material recovered in Site 552A is ideal for detailed studies of climatic evolution in the ocean adjacent to the north-west European region where the Plio–Pleistocene continental record is best known.

Seasonal fluctuations in deep-sea sediment community oxygen consumption: central and eastern North Pacific

K. L. Smith Jr & R. J. Baldwin

Marine Biology Research Division, A-002,
Scripps Institution of Oceanography,
La Jolla, California 92093, USA

Historically the deep sea was viewed as a homogeneous environment in time and space characterized by high hydrostatic pressure, low temperature and low food supply[1,2]. The highly diverse but low-density communities of organisms[3,4] occupying this environment were dependent on a slow, constant rain of small particulate organic matter from the overlying surface water for food. This material slowly settled through thousands of metres of the water column, dampening any pulses in primary production at the surface. The rate at which this 'constant' food source was used was found to be slow[5–8]. However, there was early evidence[9–12], with much recent support[13–17], that some deep-sea animals exhibited seasonal reproduction. In addition, the flux of small particulate organic matter to the deep-sea floor has been shown to be seasonal and in phase with rates of surface primary productivity[18–20]. We report here the first evidence of seasonality in biological rates in the deep sea: *in situ* rates of sediment community oxygen consumption at two abyssal stations in the central and eastern North Pacific are highest in early summer, decreasing to the lowest rates in late autumn and winter.

We have measured sediment community oxygen consumption (SCOC) seasonally at two stations over the past 6 yr: Station CNP in the oligotrophic central North Pacific north of Hawaii (31° N, 159° W; water depth 5,900 m), and Station C in the eutropic eastern North Pacific, west of the southern California Continental Borderlands (32°33′ N, 120°31′ W; water depth 3,815 m).

Sediment community oxygen consumption was measured *in situ* using a free vehicle grab respirometer (FVGR)[21,22]. This instrument consists of an integrated flotation and instrument tripod which is capable of continuously measuring the dissolved oxygen consumed by the undisturbed sediment and overlying water in four replicate grabs (413 cm^2 each). Polarographic oxygen sensors measure the dissolved oxygen tension in each grab with amplified outputs continuously recorded in the instrument package. Each sensor is calibrated using chilled saturated and nitrogen-purged seawater as limits and corrected for hydrostatic pressure effects and electrode oxygen consumption. Initial and final control bottom-water samples were incubated on the FVGR for each deployment (≤2.7 days at Station C, ≤4.9 days at Station CNP). On recovery of the FVGR, the undisturbed sediment with overlying water was analysed for macrofauna abundance and biomass, and organic carbon and total nitrogen. Total oxygen consumption rates, corrected for the overlying water rates in each grab, yielded SCOC rates[23]. Sediments in two or three grabs from each FVGR deployment were sieved through a 297-μm mesh screen on board ship and the abundance and wet weight biomass of the retained macrofauna determined in the laboratory. Small aliquots of surface sediment (0–1 cm) from each grab were frozen for CHN analysis in the laboratory where these samples were acidified with 0.1 M HCl, dried, and three replicate samples analysed using a Perkin-Elmer 240C CNH analyser.

Characterization of each bottom station is presented in Table 1. Variations of the sediment biological and chemical parameters measured are large and may represent intra-station heterogeneity.

Rates of SCOC at both stations were significantly higher ($P < 0.05$) in June than in November (Station CNP) and February (Station C) (Fig. 1). At Station CNP, June rates of SCOC were almost four times higher than in November. The high and low measured rates of SCOC in June and November bracketed intermediate values measured in August over two consecutive years. The non-significant difference ($P > 0.05$) between the SCOC rates measured in August of 1978 and 1979 suggests a repeatable pattern.

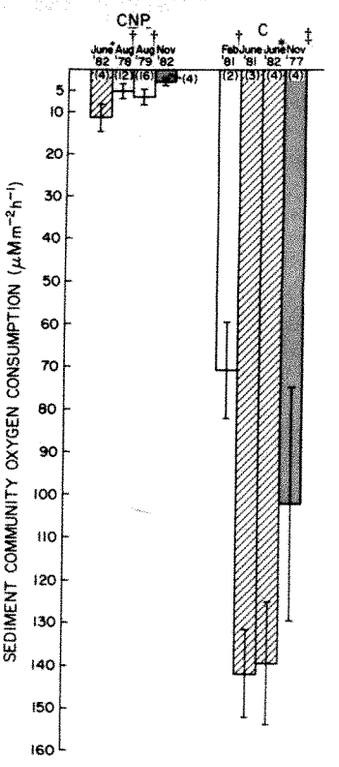

Fig. 1 Sediment community oxygen consumption measured *in situ* on a seasonal basis at Stations CNP and C. Mean rates with standard deviations are presented; the number of replicates is given in parentheses. * † ‡ Values reported previously (refs 23, 24 and 21, respectively).

Although substantially higher rates of SCOC were measured at Station C, a pattern similar to Station CNP is exhibited. Mean rates of SCOC are twice as high in June as in February (Fig. 1) with intermediate rates measured in November. These seasonal measurements of SCOC at both stations fall within the range of values measured sporadically at various depths and temperatures in the world oceans[24–28].

We propose that the fluctuations in SCOC measured at three different times of the year at both stations reflect seasonal variations in biological rates in the deep sea. The logical question is what causes such fluctuations in a seemingly constant environment. On the hypothesis[29] that the environment is food-limited, the most obvious answer is food supply; food energy used by these soft-bottom abyssal communities is ultimately derived from primary production in the euphotic zone. On a variety of temporal scales, a fraction of this production must reach bottom waters directly by sinking, diffusion and advection, indirectly by trophic transfers, or by a combination of both. This food can exist in three forms: (1) small particulate organic matter, (2) large organic falls and (3) dissolved organic matter.

(1) The flux of small particulate organic matter has not been measured seasonally in our study areas. However, a correlation has been shown between the annual cycle of surface primary productivity and the flux of small particulate organic matter reaching abyssal depths in the western North Atlantic[18] and eastern tropical Pacific[19]. The close synchrony between the annual cycles of surface primary productivity and particulate organic matter collected by sediment traps at 3,200 m (ref. 18) and 3,560 m (ref. 19) suggests rapid settling rates (>65 m per

Means ± s.d. are presented where more than one grab was sampled (number of replicates in parentheses). Macrofaunal biomass for Station C in November excludes two large animals per grab—inclusion of these animals would increase biomass to 24,190 ± 13,407.0 mg wet wt m^{-2}.
* † ‡ Values previously reported (refs 24, 21 and 23, respectively).
§ Value rounded to nearest degree (ref. 21).

day) in both areas[19,30]. More precise estimates of sedimentation rates may be determined using time-lapse photography. Billet *et al.* report rates of 100–150 m per day in the north-east Atlantic[20]. Although complete seasonal measurements of primary productivity are lacking for our two stations, data are available for areas in close proximity.

Seasonal rates of surface primary productivity are well documented for the Southern California Bight, an area 17 miles inshore of Station C. Our high rates of SCOC in June and low rates in February correlate well with the seasonal productivity maxima between March and July[31], allowing for sinking rates of ≤38 days[20] over the 3,800-m water column.

A less clear picture of primary productivity exists for the central North Pacific. Early estimates of productivity in the central gyre area recorded winter peaks in primary productivity corresponding to increased mixing of subsurface nutrient-rich water with surface water[32]. Although Hayward and associates[33], on analysing recent ^{14}C measurements at a station south of Station CNP, found no obvious trends in primary productivity, seasonal variation may be masked by the large intraseasonal variability. One indication of seasonal variation is the existence of a high subsurface oxygen maximum in this same area in summer, which, if photosynthetically produced, would yield substantially higher estimates of primary productivity than indicated by the ^{14}C method[34]. Of the three times of the year measured, SCOC at Station CNP was highest in June and lowest in November (Fig. 1). If we assume that the photosynthetically produced particulate organic matter which escapes the euphotic zone sinks at a rate of 100–150 m per day (ref. 20), then one would expect this food supply to reach the bottom community within 2 months. Therefore, our data predict that peaks in primary productivity would occur in spring. However, faster sinking rates up to 1,028 m per day have been reported for zooplankton and midwater fish faecal pellets[35,36] yielding bottom arrival times of less than 10 days at 5,900 m.

(2) The contribution of large organic falls (for example, carcasses of pelagic fishes and squid, shallow benthic and terrestrial plant remains) to the food supply of the deep sea is unknown[37]. Large pelagic fishes such as tuna, *Thunnus alalunga*, undergo seasonal migrations in the North Pacific with high numbers occurring in winter in the vicinity of Station CNP, and in the spring and early summer in the vicinity of Station C[38,39]. Although seasonal mortality rates are unknown for these and other large pelagic animals, the potential importance of this food source would increase during periods of maximum abundance. In addition, Station C may be influenced by seasonal inputs of drift kelp; peak kelp abundances appear on beaches and probably offshore during the stormy winter months[40].

(3) Although dissolved organic matter (DOM) represents a large pool of potential food in the deep sea, measurements of DOM in the central and eastern North Pacific near the sediment–water interface reveal this source to be 'old' and refractory[41,42]. However, seasonal measurements of combined dissolved and particulate organic carbon at 300–1,500 m depth in the central Pacific do show significantly higher concentrations in the winter than in summer[43].

The seasonality of any of these potential food sources may be influenced more directly by abyssal advection than by surface and atmospheric conditions. Abyssal currents have been shown to have seasonal signals in the eastern North Atlantic, generated by high surface wind stress in winter with temporal lag and decay in magnitude with depth[44]. This, coupled with observations of temporal variability in the nepheloid layer at abyssal depths in the western North Atlantic[45], suggests the potential impact of seasonal pulses on abyssal advection of food.

Our results suggest a seasonal pattern in SCOC which is related to the seasonal productivity regime of the overlying waters in the eutrophic eastern boundary current region (Station C) and possibly in the oligotrophic central gyre region (Station CNP). Deep-sea areas can no longer be considered to be in static equilibrium exhibiting constant biological rates, but must be examined as components in dynamic equilibrium with the overall open ocean ecosystem. Mass balance calculations of organic matter remineralization which are based on a single measurement in time must be re-evaluated considering fluctuations which in the case of SCOC can vary by as much as a factor of four between seasons.

Phosphorus limitation of net production in a confined aquatic ecosystem

S. V. Smith

Hawaii Institute of Marine Biology, University of Hawaii, PO Box 1346, Kaneohe, Hawaii 96744, USA

M. J. Atkinson

Department of Zoology, University of Western Australia, Nedlands, Western Australia 6009

The sediment composition of confined aquatic ecosystems with little terrigenous input reflects net ecosystem production. Here we present nutrient budgets for one such system, Shark Bay in Western Australia, which suggest that net ecosystem production is limited by the oceanographic delivery of P, while the system meets its N requirements by nitrogen fixation. We suggest that N versus P limitation of the net production of aquatic ecosystems reflects the degree of confinement of those systems.

An aquatic ecosystem isolated from exogenous inputs of organic material must have a long-term net organic production rate which equals or exceeds zero. Were such an isolated system not biased towards net autotrophy, the biomass and sedimentary organic materials would be consumed and the system would eventually collapse. If the system also does not export organic material, then the sediments must reflect the long-term net production of organic material. While these relationships must be true in principle, they rarely have application: organic additions or losses usually obscure the sedimentary record of net organic metabolism.

Shark Bay, Western Australia (Fig. 1), is a large (13,000 km^2), seagrass-dominated coastal lagoon[1] which might be expected to preserve this theoretical relationship between net organic production and sediment composition. The bay is surrounded by desert; there is virtually no input of fresh water via runoff, rainfall or groundwater. Exchange of materials with the ocean is slow; average water residence time in the bay, estimated from water and salt budgets[1] exceeds 1 yr.

Net uptake of dissolved inorganic materials from incoming water, although very slow, nevertheless drastically modifies the water composition. This modification represents the net signal of biogeochemical fluxes, integrated over the long water residence time[1]. For example, ocean water entering the bay has a reactive P concentration of ~0.2 mmol m^{-3}; reactive P in the bay decreases to ~0.03 mmol m^{-3}.

We refer to budgets of net C and P uptake derived from a box model of water and salt balance as the 'oceanographic budgets'. The rate term for these budgets is derived from net evaporation rates[1]. Because of the virtual isolation of the bay from particulate inputs and outputs, we hypothesized that the sediments should reflect the net production. We refer to the sedimentary record of net production as the 'sediment budgets'. Because the absolute sedimentation rate of Shark Bay is unknown, we do not have a normalizing parameter for the sediment budgets. We therefore compare data for the oceanographic and sediment budgets by means of material ratios, thus removing the absolute rate terms from both sets of budgets.

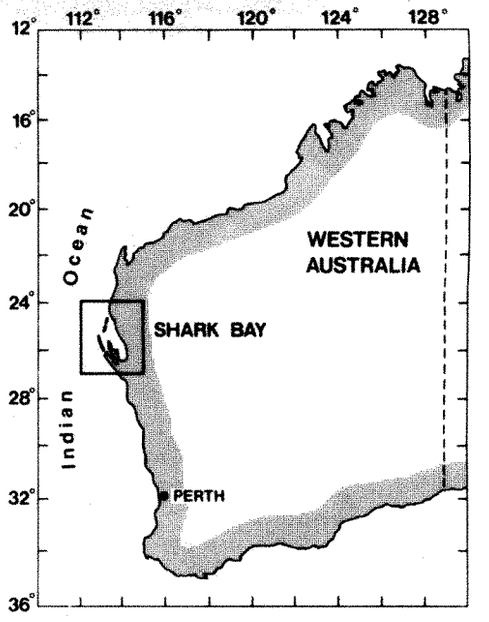

Fig. 1 Location map of Shark Bay, Western Australia.

Water loss from net evaporation is compensated by net advective (tidal) inflow. The salt balance is maintained by advective inflow and loss by horizontal eddy diffusion. Deviation of the concentrations of other chemical constituents from proportionality with salinity is attributed to net uptake.

Table 1 is a summary of net uptake of C into $CaCO_3$ and the net uptake of both C and reactive P into organic materials, as derived from the oceanographic budgets. Note that 27% of the carbon taken up enters the organic fraction and the remainder enters $CaCO_3$. Moreover, the molar ratio of C to P taken up by the net production of organic materials is ~320:1.

Sediment grab samples were collected along the same transect through the eastern gulf of Shark Bay as was used for the oceanographic budgets. Samples were dried at 110 °C. Weighed aliquots were muffled at 550 °C for 2 h, re-weighed, remuffled at 1,000 °C, and weighed again. Combustion at 550 °C oxidizes organic materials[2]. Organic carbon was calculated as 40% of the weight loss at 550 °C. Combustion of $CaCO_3$ at 1,000 °C drives off CO_2. Inorganic carbon was calculated to be 27% of this latter weight loss.

This procedure gives results more reproducible for the C composition of organic-poor calcareous sediments than do CHN analyses according to the technique of Hirota and Szyper[3]. We found no evidence of significant carbonate loss at 550 °C, although some Mg calcite loss could have escaped our notice[2].

Total sediment N was determined by standard colorimetric techniques after sulphuric acid Kjeldahl digestion of samples, and total P was determined colorimetrically after sample digestion with nitric and perchloric acids.

Table 2 summarizes sediment composition. The inorganic C content of the sediments averages 8.2 mmol g^{-1} (82% $CaCO_3$). The average organic C content of the sediments is 2.1 mmol g^{-1}

Table 1 Net rates of carbon and phosphorus uptake by biogeochemical processes in the eastern gulf of Shark Bay

Process	Rate (mmol per m^2 per day)
$CaCO_3$ production	3.2
Organic carbon production	1.2
Phosphorus uptake	0.0037

Rates derived from Smith and Atkinson[1].

Table 2 Sediment composition in the eastern gulf of Shark Bay

Component	Amount (mmol g^{-1})
Inorganic C	8.2 ± 0.18 (38)
Organic C	2.1 ± 0.10 (39)
Total N	0.05 ± 0.06 (39)
Total P	0.007 ± 0.005 (39)

Values are the mean ± s.d. (n).

(6% organic material). Thus, no more than 12% of the sediments come from non-carbonate, inorganic sources.

Organic C represents 20% of the C in the sediments, about one-quarter lower than the organic fraction of C uptake derived from the oceanographic budgets (Table 1). Broecker and Takahashi[4] were unable to reconcile an oceanographically determined C budget for the Bahama Banks with the organic C content of sediments there. In most settings where the biomass in the system studied exceeds that of the surrounding waters, there may be significant net export of organic materials by advective and mixing losses and by the migration of organisms. Extremely slow water exchange and apparently small migration fluxes obviate such a problem in Shark Bay. Even so, the slight discrepancy between the organic C fraction of the oceanographically determined C uptake and the organic C fraction of the sediments may represent loss of organic materials.

The average P content of the sediments is 0.007 mmol g^{-1}, and the sediment molar ratio of organic C to P is 300:1 (Table 2), not significantly different from the uptake ratio derived from the oceanographic budget (Table 1). From the correspondence between the oceanographic and sediment budgets for C and P, we are confident that the sediments adequately reflect net ecosystem uptake. Sediment N composition should therefore reflect net N uptake. The sediment N content is 0.05 mmol g^{-1} (Table 2), and the molar C:N:P ratio of the sediments is ~300:7:1.

We now use the oceanographically derived rates of C and P uptake and the sediment C:N:P ratio to scale N uptake, and we derive a rate of 0.03 mmol per m^2 per day. If an error exists in this estimate, it should be of the same order as the discrepancy between the oceanographic and sediment C budgets (<25%). The net N uptake by this system is <0.04 mmol per m^2 per day.

Nitrate plus ammonia concentration throughout the bay is less than 0.5 mmol m^{-3}, and there is no coherent pattern of spatial variation (Smith and Atkinson, unpublished data). Applying this average concentration and a nitrogen/salinity gradient of 0 to our box model[1] yields an oceanographic supply of N of 0.002 mmol per m^2 per day; less than 10% of the N being taken up into the sediments can be supplied by oceanographic input. The remainder must enter by other pathways, with atmospheric N fixation being the most likely one.

We did not measure N fixation, nor do we believe that such measurements are directly relevant. It would be impossible to estimate the N fixation rate for such a large, heterogeneous area from a few spot measurements of local N fixation, and the phenomenon of N fixation is adequately documented. Capone and Carpenter[5] report N fixation rates of 1–0.02 mmol per m^2 per day for environments ranging from seagrass beds to bare estuaries and shallow benthic environments. Our initial estimate of N fixation in Shark Bay falls near the low end of this range.

The sedimentary end product of Shark Bay organic materials appears greatly depleted with respect to N compared with the N/P ratios of materials being produced. The low sediment N/P ratio (7:1) compared with either plankton (16:1 (ref. 6); confirmed with our own data for Shark Bay) or benthic plants (30:1 (ref. 7); confirmed for Shark Bay) suggests that N is more readily released from particulate organic materials in the sediments than are P and C. This release may represent denitrification[8]. In that event, our estimate of N fixation might be too low by 2–4-fold. The upper limit of possible N fixation in Shark Bay (<0.16 mmol per m^2 per day) is still well within the range for comparable environments elsewhere[5].

We offer the following simple model to explain our observations. The two primary components to the model are the flushing rate of water through the system and the presence of N fixation as a supplement to the oceanographic (and, in other systems, land-derived) N sources.

As summarized above, marine plants ordinarily contain 16 to 30 times as much N as P, yet surface seawater typically has an inorganic N/P ratio of ≤10. Surface seawater is thus deficient in N, relative to the nutritional requirements of plants[9]. A highly productive environment subjected to such N-deficient water may fix N (for example, coral reef flats[10]); however such open environments export the locally fixed N (ref. 11) before the supply of P has been lowered measurably[12]. By contrast, confined systems such as Shark Bay will accumulate fixed N. They supplement their N deficiency until P is exhausted. The system-wide rates required to exhaust available P are small relative to documented community or organismic N fixation rates[5]. Therefore the systems clearly have the capacity to 'fine-tune' N fixation rates to use available P. The supply of N is effectively limitless; the supply of P is not.

The apparent conflict between N and P limitation of net community production in aquatic systems can be resolved into extremes of a continuum. Many open systems receiving water which is deficient in N fail to accumulate N and are examples of open, N-limited systems[9]. The net community production of progressively confined systems will tend towards P limitation, because of accumulation and recycling of internally fixed N until P is exhausted. Isolated hypersaline coastal lagoons such as Shark Bay, some relatively enclosed coral atoll lagoons[13], many lakes with long water-residence times[14], and the whole of the world's oceans[15] are examples of confined, P-limited ecosystems.

We thank C. Crossland, J. Hansen, A. Hatcher, B. Hatcher, R. Johannes, F. Mackenzie and D. Smith for critical comments on the manuscript.

Mallomonadacean microfossils provide evidence of recent lake acidification

John P. Smol

Department of Biology, Queen's University, Kingston, Ontario, Canada K7L 3N6

Donald F. Charles & Donald R. Whitehead

Department of Biology, Indiana University, Bloomington, Indiana 47405, USA

The Mallomonadaceae (Chrysophyceae), a group of flagellated algae commonly found in freshwater systems, are characterized by an armour of overlapping siliceous scales that are taxonomically diagnostic[1]. Mallomonadacean scales are usually abundant and well preserved in lake sediments[2]. Previous palaeolimnological studies have used the stratigraphic distribution of mallomonadacean assemblages to document patterns of lake eutrophication[2–5]. Our data demonstrate that the distribution of certain mallomonadacean taxa is also closely related to lakewater *p*H, that stratigraphic analyses of fossil scales can be used to indicate past changes in lake acidity, and that such stratigraphic studies provide important insights concerning the responses of sensitive lake systems to acid deposition.

Subfossil mallomonadacean assemblages from the surface sediments of 38 lakes in the Adirondack Mountains (New York, USA) have been studied with respect to the limnological factors that appear to influence the distribution of individual species and the characteristics of assemblages[6]. The Adirondack area is a largely forested and mountainous region that contains about 3,000 lakes and ponds, and is one of the most important lake regions in North America. The lakes are generally dilute and unproductive. The area receives intense acidic precipitation and, since many lakes have been affected[7,8], it is important that we be able to determine the recent acidification histories of sensitive lake systems. Detailed information on lake locations, morphometry, and chemistry has been presented elsewhere[9].

Surface sediment samples (0–1 cm) were taken from the deepest areas of the study lakes using a modified Cushing and Wright piston corer[10]. Because mallomonadacean scales are siliceous, sediment digestions and microscopic techniques were the same as those used for fossil diatoms[2]. Although electron microscopy is required to confirm taxonomic identifications, scales can usually be distinguished to the species level with light microscopy. An average of 600 scales was counted from each sediment sample. A total of 30 species from five genera was identified[6].

Reciprocal averaging and cluster analyses indicated that *p*H and factors correlated with it exerted the greatest influence on mallomonadacean assemblages[6]. The distributions of individual taxa were plotted against each of the 21 limnological factors studied (as in Table 1). Scales of *Mallomonas hindonii* Nicholls and/or *M. hamata* Asmund (Fig. 1) were especially common in acidic lakes (Fig. 2). Notable exceptions were the three bog lakes (pH < 5.4) in which only trace populations were noted, and in the two highest elevation lakes (pH < 4.8) where scales of *M. hamata* were never observed. The distribution of these two taxa did not correlate closely with any of the other limnological factors studied. These data suggest that *M. hindonii* and *M. hamata* are reliable indicators of acidic non-bog conditions. In the few acidic lakes where neither of these two species were common, scales of *Synura echinulata* Korsh. were usually abundant.

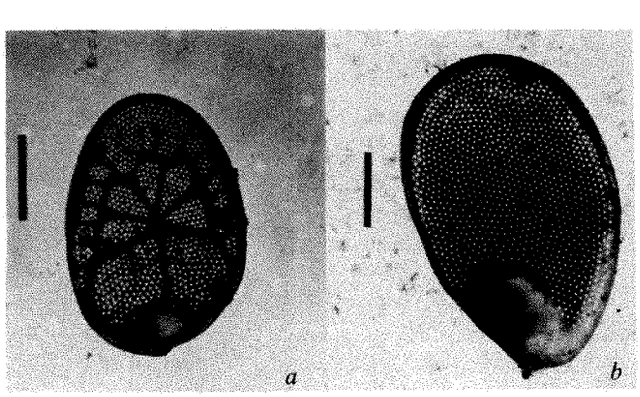

Fig. 1 Transmission electron micrographs of scales of *Mallomonas hindonii* (*a*) and *Mallomonas hamata* (*b*). Scale bar, 1 μm.

Table 1 Morphometric, physical and chemical characteristics of Deep Lake

Lake characteristic	
Surface area	11 hectare
Maximum depth	24 m
Elevation	789 m
Watershed area	72 hectare
*p*H	4.7
Alkalinity	−18 μequiv. l^{-1}
Conductivity	29 μS cm^{-1} at 25 °C
Colour, true	7.5 Pt. Co units
Colour, Forel-Ule, median	7 units
Secchi disk transparency	8.4 m
P, total	3.1 μg l^{-1}
Chlorophyll *a*	1.7 μg l^{-1}
Ca	64 μequiv. l^{-1}
Mg	26 μequiv. l^{-1}
Na	13 μequiv. l^{-1}
K	6 μequiv. l^{-1}
SO_4	150 μequiv. l^{-1}
Cl	7 μequiv. l^{-1}
NO_3	12 μequiv. l^{-1}
Al, total	611 μg l^{-1}
SiO_2	2.7 mg l^{-1}

Alkalinity, *p*H, conductivity, and true colour data are for surface (0.5 m) samples. Total P, chlorophyll *a*, cations, anions, Al, and SiO_2 data are for composite lake-average samples. All data are 1978–1979 summer (May–August) averages except for cation, anion, Al, and SiO_2 which are for samples taken 1 September, 1979.

Because many lakes in the Adirondacks have been affected by anthropogenic acidic precipitation[7], a stratigraphic analysis of fossil Mallomonadaceae was initiated to establish whether these microfossils could be used to trace past changes in lakewater *p*H. Deep Lake (43°36′58″ N, 74°39′52″ W; Table 1) was chosen for this study because of its suitability for such a palaeological study. It is a headwater lake with a deep cup-shaped basin, it is at a relatively high elevation (789 m), is acidic (pH = 4.7), and is similar to other lakes in the area that have recently become more acidic[8]. The drainage basin is underlain by granitic gneiss bedrock that is covered by thin tills and soils. Watershed vegetation is a mixed deciduous–coniferous forest consisting largely of sugar maple (*Acer saccharum* Marsh.), yellow birch (*Betula alleghaniensis* Britton.) and American beech (*Fagus grandifolia* Ehr.), with lesser amounts of red maple (*Acer rubrum* L.) and red spruce (*Picea rubens* Sarg.). The area was logged in the late 1800s, and then again in the early 1950s (F. Lamphear, personal communication). Our unpublished palynological data do not indicate any marked differences in vegetation succession between these two episodes of disturbance. The watershed is in the West Canada Creek Wilderness Area and contains no cultural development other than hiking trails. Historical data indicate that Deep Lake probably became more acidic sometime between the 1930s and the mid-1950s. Professional guides reported good fishing for brook trout (*Salvelinus fontinalis*) in Deep Lake during the 1930s. However, although Deep Lake was stocked annually with brook trout fingerlings between 1951 and 1968, only three trout were

0028–0836/84/070628—03$01.00

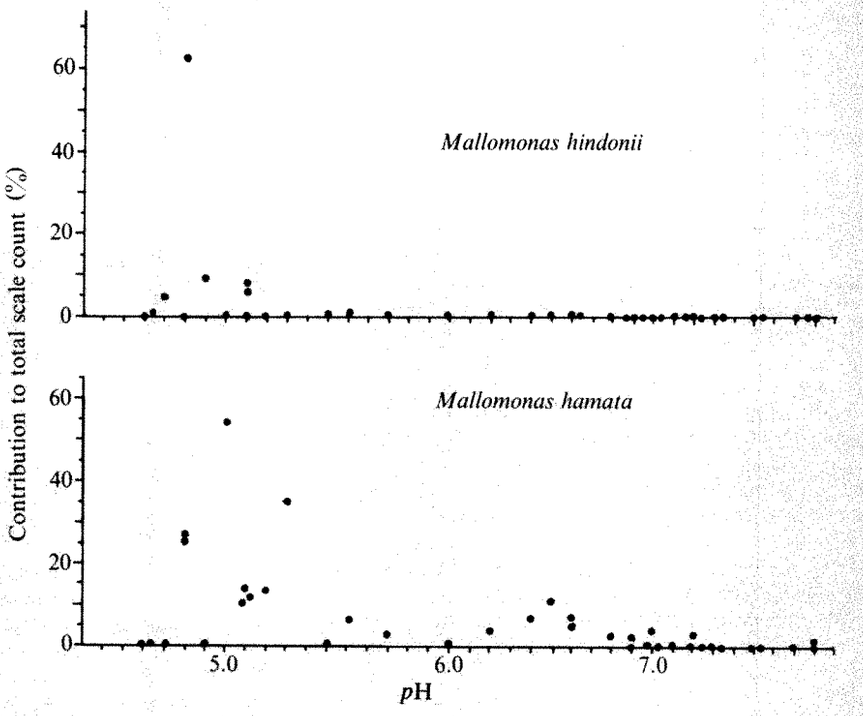

Fig. 2 The percentage contribution of *Mallomonas hindonii* and *M. hamata* scales plotted relative to the *p*H of each of the 38 study lakes.

captured during fish surveys in 1954, 1964 and 1965. No fish were caught during 1966, 1967 and 1968 surveys[11]. Because brook trout usually cannot survive in lakes with a *p*H < 5.0 and high Al concentrations[12], conditions that currently exist in Deep Lake (Table 1), lake acidification was probably responsible for the disappearance of fish populations.

A 60-cm-long core was removed from the centre of Deep Lake and sectioned in the field at 1 cm intervals. The rise in non-arboreal pollen [ragweed (*Ambrosia*) and other weedy taxa] was recorded at the 5–6 cm level (Fig. 3). This horizon can be dated circa AD 1850, since an examination of historical records indicates that land clearance in the region southwest of the Adirondacks intensified at this time. Although the scales of 13 mallomonadacean taxa were identified in the Deep Lake stratigraphy, only six species ever represented more than 2% of the total scale sum (Fig. 3). Throughout the lower part of the core, assemblages are dominated by *Mallomonas crassisquama* (Asmund) Fott with lesser amounts of *M. punctifera* Korsh. and *M. acaroides* Perty em. Iwanoff. However, a significant change occurs near the 3 cm level. There is a marked increase in *M. hindonii* and *M. hamata*, and, to a lesser extent, *Synura echinulata*. No changes in Mallomonadaceae coincided with the rise in non-arboreal pollen.

We believe that this shift in species composition was in response to lake acidification. As previously noted, *M. hindonii* and *M. hamata* are indicative of acidic lakes. Among the 38 Adirondack study lakes, *Synura echinulata* scales were also most abundant in the surface sediments of acidic lakes (for example, 81% of the total scale sum in Lake Tear of the Clouds, *p*H = 4.6; 74% in Mountain Pond, *p*H = 4.7; 59% in Lake Colden, *p*H = 5.0). In contrast, *M. crassisquama*, which is the most widespread *Mallomonas* sp. in the world[13–15], occurred only rarely in

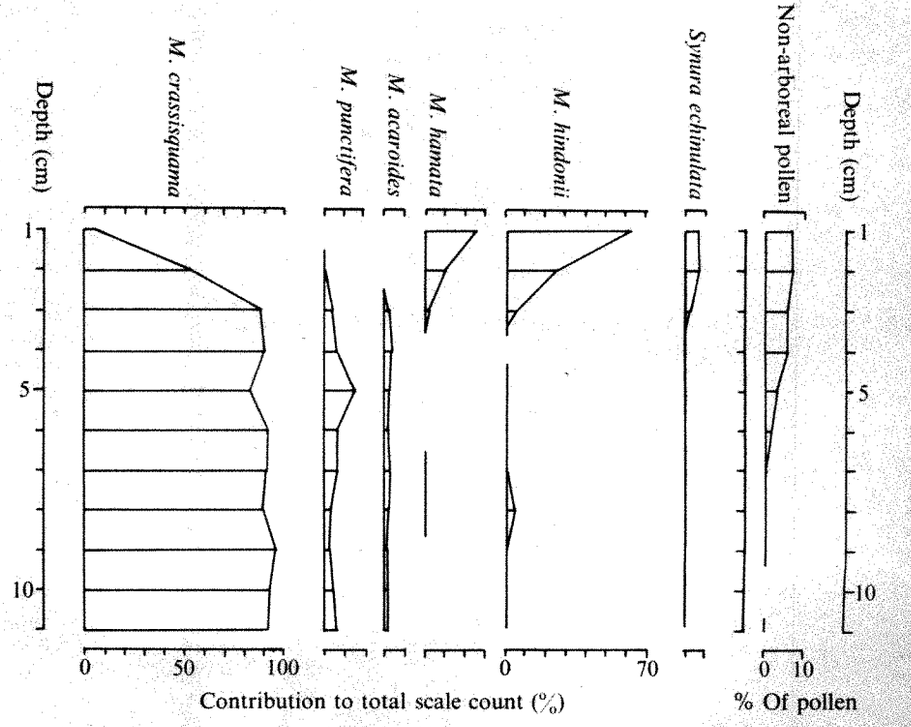

Fig. 3 Percentage diagram of the stratigraphic distribution of Mallomonadaceae in the Deep Lake sediments. The 15-cm and 20-cm levels were also analysed, but they were similar to the 11-cm level and are not presented here. An average of 600 scales was identified and enumerated from each level. *Mallomonas punctifera* Korsh. is synonymous with *M. pulchella* (Kisselev) Cronberg & Kristiansen and *M. reginae* Teil[15].

assemblages from lakes with a $pH < 5.0$. A similar distribution for this taxon has been reported in other areas[13]. Similarly, *M. punctifera* was more abundant in circumneutral to slightly alkaline waters, and reached its highest abundance in the surface sediments of Clear Pond ($pH = 7.2$).

The earliest date at which the shift in Mallomonadaceae could have occurred was approximately 60–70 years ago. This estimate is made by assuming a constant sedimentation rate (~25 years cm^{-1}) between the rise in non-arboreal pollen at the 6 cm level (~1850) and 1979, the year the core was taken. However, the sediment was less dense at the top of the core, so that accumulation rates must have been greater near the sediment surface, and the shift in Mallomonadaceae undoubtedly occurred more recently. Nevertheless, the acidification began at least 30 years ago, as the earliest limnological data available for Deep Lake are from 1954 when the *p*H was already recorded as low as 4.7[11]. This is consistent with fisheries data cited previously, since it is likely that the decline in lake *p*H preceded the decline in fish populations. The inferred acidification probably resulted in large part from the increased atmospheric deposition of strong acids.

Our interpretation of Deep Lake's recent history is further substantiated by the stratigraphic distribution of diatoms. Before the proposed period of acidification, the diatom flora consisted of a diverse assemblage of indifferent to acidophilous taxa [for example *Frustulia rhomboides* (Ehr.) De T., *Anomoeoneis serians* var. *brachysira* (Bréb. *ex* Kütz.) Hust.]. However, in the surface sediment, the assemblage is dominated (56%) by an as yet undescribed taxon [*Fragilaria* cf. *virescens* var. 1,]. Based on Charles' diatom survey of the Adirondack lakes[9], this new *Fragilaria* is an acidobiontic form, reaching its highest abundance in lakes with a $pH < 5.0$.

Our data indicate that the Mallomonadaceae are sensitive to changes in *p*H, and can therefore provide important palaeoecological data on lake acidification. Because sediment preparations for mallomonadacean scales and diatoms are identical, scales can easily be incorporated into palaeolimnological studies where diatoms are being analysed. In contrast to euplanktonic diatoms, which appear to be excluded in waters with $pH < 5.8$–6.0[9], several mallomonadacean taxa thrive in acidic lakes. Hence, mallomonadacean scales probably represent the only algal microfossils that will reflect the euplankton in acidic lakes. Palaeolimnological studies that utilize both diatom frustules and mallomonadacean scales should provide a more accurate reconstruction of lake history.

This study was supported in part by NSF grants DEB 77-03907 (to D.R.W. and P. M. Vitousek) and DEB 79-12210 (to D.R.W.), and by the Natural Sciences and Engineering Research Council of Canada (operating grant A-808 to Dr S. R. Brown and as fellowships to J.P.S.). We thank Drs S. R. Brown, M. M. Boucherle, T. Oliver and G. Cronberg for helpful comments, and Ms F. Murrin for assistance with electron microscopy.

Photodriven charge separation in a carotenoporphyrin–quinone triad

The key steps in the photosynthetic conversion of light to chemical potential energy include not only photodriven charge separation, but also prevention of the back-reaction (charge recombination). Although the first of these steps has been achieved in several biomimetic solar energy conversion systems, retarding the back-reaction has proved more difficult. This may be accomplished by rapidly moving the electron, the hole, or both away from the site of excitation to more stabilizing environments. In photosynthetic membranes, the electron is transferred sequentially over several closely coupled molecules, including tetrapyrroles and quinones[1–3]. In semiconductor/liquid interfacial systems both the electron and the hole migrate following excitation[4,5]. We now report that substantial slowing of the back-reaction has been achieved with a tripartite molecule in which a long-lived photodriven charge-separated state of relatively high potential is formed from an excited singlet state in accordance with the above principles. This molecular triad (compound I) consists of a tetraarylporphyrin covalently linked to both a carotenoid and a quinone. In solution, excitation of the porphyrin moiety by visible light results in the rapid (<100 ps) formation of a transient species $C^{+\cdot}$–P–Q–$^{\cdot-}$, with a lifetime on the μs time scale and an energy more than 1 eV above the ground state.

Compound I was synthesized using methods previously developed for carotenoporphyrins[6–10]. The 7′-apo-7′-(4-carboxyphenyl)-β-carotene was prepared by the Wittig reaction of the ylide of 4-carbomethoxybenzyltriphenylphosphonium bromide with β-apo-8′-carotenal, followed by saponification of the resulting methyl ester. The 5,15-bis(4-aminophenyl)-10,20-bis(4-methylphenyl)porphyrin was prepared by reduction of the corresponding dinitro porphyrin, and the carotenoid was linked to this porphyrin using dicyclohexylcarbodiimide and 4-dimethylaminopyridine. Coupling of this carotenoporphyrin to 2,5-diacetoxyphenylacetic acid yielded compound III, which was deacetylated with potassium borohydride to generate hydroquinone II. The oxidation of II to I was achieved with 2,3-dichloro-5,6-dicyano-1,4-benzoquinone or lead oxide. The fast atom bombardment (FAB) mass spectrum of III yielded a monoisotopic mass ($M+1$) of 1,423.5 (calculated for $C_{96}H_{90}N_6O_6$; 1,423.7).

The 500 MHz ^{1}H-NMR spectra of I, II and III in $CDCl_3$ solution support the assigned structures and also yield conformational information. The aromatic, 7′ and 8′ proton resonances of the carotenoid portions of the molecules are shifted downfield from their positions in the corresponding carotenoid aniline amide, whereas the chemical shifts of the remaining carotenoid protons are virtually unchanged. These downfield shifts (≤0.16 p.p.m.) indicate that the carotenoid is in the deshielding region of the porphyrin ring current field. Quantitative calculations[11] for III show that the carotenoid chain lies approximately in the plane of the porphyrin and is extended away from the

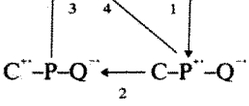
© 1984 Macmillan Journals Ltd



porphyrin π-electron system (Fig. 1). The protected hydroquinone side chain is also in an extended, rather than folded, conformation. Ring current calculations yield the conformation shown in Fig. 1, and are consistent with rapid rotational jumps of the $-CH_2$-diacetoxyphenyl residue among the various equilibrium positions about the CH_2–CO bond, only one of which is shown. Conversion of III to II or I results in small changes in chemical shifts for the protons of the quinone side chain, as expected, and has very little effect ($\Delta\delta \leq 0.05$ p.p.m.) on the porphyrin or carotenoid proton resonances. Thus, it is reasonable to conclude that the time average solution conformation of each of these triads is also extended with the carotenoid and quinone moieties rather widely separated.

Nanosecond flash excitation[12] at 600 nm of a solution of compound I in CH_2Cl_2 resulted in the transient absorption spectrum shown in Fig. 2 with $\lambda_{max} = 970$ nm and $t_{1/2} \sim 170$ ns. This signal was not observed with II or III. Figure 2 also shows the transient absorption after pulse radiolysis of III and of a model for its carotenoid component. The assignment of the pulse radiolysis[13] spectrum, and therefore the flash photolysis spectrum, to a carotenoid cation radical is straightforward[14–17]. A carotenoid ground state bleaching signal ($\lambda_{max} \sim 460$ nm, $t_{1/2} \sim 170$ ns) appeared concomitantly with the cation radical absorption. (A small, long-lived bleaching component ascribed to a carotenoid triplet arising from trace amounts of II was also observed.) Saturation of the CH_2Cl_2 solution with tetra-*n*-butylammonium tetrafluoroborate increased the yield of carotenoid cation radical by a factor of at least six, increased $t_{1/2}$ to ~ 2.5 μs, and blueshifted the absorption maximum to ~940 nm. In acetonitrile solution $\lambda_{max} = 910$ nm and $t_{1/2}$ was ~3 μs.

Picosecond techniques were used to measure the rise of the cation radical (Fig. 3). An absorbance increase was observed at 950 nm and assigned to the carotenoid cation radical, as confirmed by a spectrum taken at 500 ps. The rise of the cation radical occurs within ~100 ps, and is delayed by ~30 ps with respect to the response time of the apparatus as determined by the photobleaching of pinacyanol chloride[18]. At 600 nm, an absorbance increase appears with the response time of the instrument and decays within 100 ps to a small residual absorption. This absorbance increase may be assigned to the porphyrin first excited singlet state (^{1}P) and/or an intermediate porphyrin cation radical (see below)[19,20].

The quantum yield of carotenoid cation radical was ~0.25 in CH_2Cl_2 solution saturated with tetra-*n*-butylammonium tetrafluoroborate. This measurement was made by a comparative method[21] using free base *meso*-tetra-*p*-tolylporphyrin in benzene as the standard ($\varepsilon_{441}(^3\text{porphyrin}) = 6.8 \times 10^4\ M^{-1}\ cm^{-1}$ (ref. 8) and $\phi(^3\text{porphyrin}) = 0.9$ (ref. 22)). An ε_{970} (carotenoid cation radical) $\sim 1.6 \times 10^5\ M^{-1}\ cm^{-1}$ was determined from the ratio of δA_{460} (the bleaching component having $t_{1/2} \sim 170$ ns) to $\delta A_{970} = 1:2.7$ and assuming[17] ε_{460} (carotenoid cation radical) $= 0.5\ \varepsilon_{460}$ (carotenoid S_0)[15–17]. In pure CH_2Cl_2, the quantum yield was ~0.04; similar values were found in acetonitrile and acetone.

The simplest scheme that is consistent with the spectroscopic observations is shown below

(minor pathways, triplet states and spin multiplicities of the ionic states are ignored). By analogy with simple porphyrin–quinone systems[19,20,23–25], it is reasonable to assume that the dominant relaxation pathway (1) from C–^{1}P–Q is quenching of ^{1}P via electron transfer to yield C–P$^{+\cdot}$–Q$^{-\cdot}$. The immediate rise of the 600-nm absorption on excitation (Fig. 3) is consistent with the formation of C–^{1}P–Q and its rapid conversion to C–P$^{+\cdot}$–Q$^{-\cdot}$. (The relative contributions of ^{1}P and P$^{+\cdot}$ to this

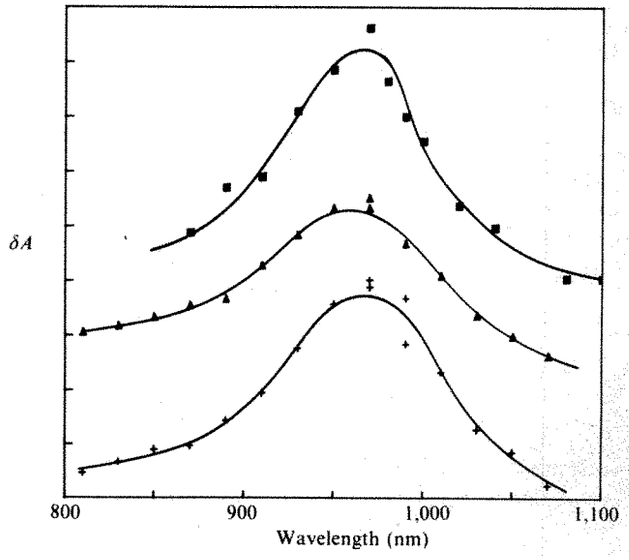


Fig. 2 Transient absorption spectra of carotenoid cation radicals. ■, Absorption spectrum immediately after 10-ns 600-nm flash excitation[12] of 10^{-5} M compound I in CH_2Cl_2. ▲, Absorption spectrum 2 μs after pulse radiolysis of argon-flushed $\sim 5 \times 10^{-5}$ M compound III in CH_2Cl_2. +, Absorption spectrum 4 μs after pulse radiolysis of argon-flushed 10^{-5} M aniline amide of 7′-apo-7′(4-carboxyphenyl)-β-carotene in CH_2Cl_2. For the pulse radiolysis experiments, radiation doses (~20 Gy per 50 ns pulse) were provided by a 12-MeV Vickers electron linear accelerator[13]. Quartz capillary cells of 2 cm optical path were used. The δA scales for the three spectra are different, and baselines have been offset for clarity.

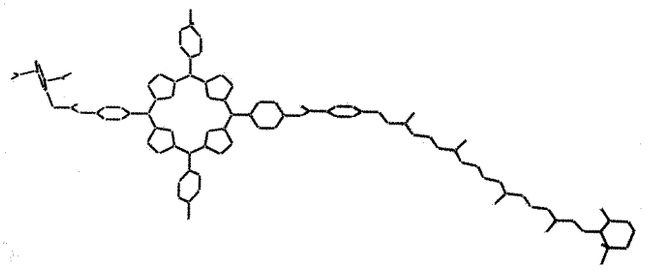

Fig. 1 Time averaged solution conformation of triad III as calculated from porphyrin ring current-induced ^{1}H-NMR chemical shift changes. The hydrogen atoms are not shown. The acetylated hydroquinone moiety is seen edge-on at the left, whereas the carotenoid extends to the right. In this perspective, the porphyrin is not coplanar with the plane of the figure. The chemical shifts of the acetyl methyl protons are consistent with rapid reorientation by π radians about the bonds linking the acetoxy oxygens to the aromatic ring.

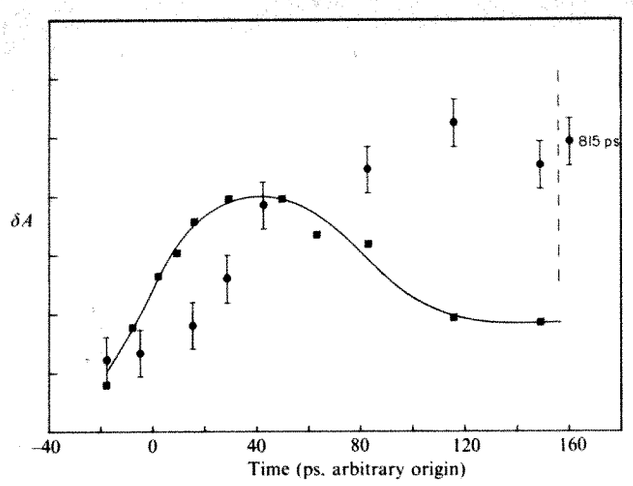

Fig. 3 Transient absorption kinetics for compound I (10^{-4} M) in CH_2Cl_2 solution saturated with tetra-*n*-butylammonium tetrafluoroborate after 532 nm pulse excitation (27 ps FWHM)[32]. The probe light was the ps continuum of light, analysed after the sample cell (1 mm path length) using Pomfret interference filters (3 nm bandwidth) centred at 600 nm and at 950 nm ($\delta A = 0.08$ per division). Each point is an average of four laser shots. The circles with error bars represent the response at 950 nm (carotenoid cation radical), whereas the squares give δA at 600 nm. The error bars at 600 nm are comparable with those at 950 nm, but have been omitted for clarity.

absorption are not resolved.) The decay of this absorption and concurrent rise of the carotenoid cation radical absorption reflect the formation of $C^{\cdot+}$–P–$Q^{\cdot-}$ (step 2). The dramatic shortening of the porphyrin first excited singlet lifetime ($\tau \sim 10$ ns for a typical porphyrin) suggests that the species C–$P^{\cdot+}$–$Q^{\cdot-}$ is formed with a quantum yield approaching unity. Furthermore, the rapid decay of ^{1}P and rise of carotenoid cation radical rule out the participation of the porphyrin triplet in the primary electron transfer process. In addition, there is no evidence for direct excitation of Mulliken-type[26] porphyrin–quinone charge transfer states, because the absorption spectra at 400–800 nm for I, II and III are identical to within 1%.

The next step in the formation of the final charge-separated state is the electron transfer process C–$P^{\cdot+}$–$Q^{\cdot-}$ → $C^{\cdot+}$–P–$Q^{\cdot-}$ (step 2) which competes with the recombination reaction (step 4). In pure CH_2Cl_2 the yield of (2) is ~4%, whereas at high salt concentration it increases markedly. This observation suggests that the outcome of the competition between (2) and (4) is strongly dependent on the ionic environment. It seems certain that the redox potential of the final state $C^{\cdot+}$–P–$Q^{\cdot-}$ is >1 V, based on $E_{1/2}$ values for related unlinked molecules[27–29]. Thus, a substantial fraction of the 1.8-eV porphyrin lowest excited singlet state has been conserved as chemical potential.

As was found with certain other carotenoporphyrins[7,8], the triads mimic antenna and photoprotective processes observed in photosynthetic membranes. In compounds II and III, singlet energy transfer (^{1}C–P–Q → C–^{1}P–Q, antenna function) is ~10% efficient. As is the case in the natural system, triplet states are formed in much greater yield when the primary acceptor is reduced (II or III) before excitation. Quenching of the porphyrin triplet state in III ($C-{}^3P-Q \rightarrow {}^3C-P-Q$) occurs in less than 20 ns, ensuring essentially complete photoprotection from singlet oxygen (a detailed report of the singlet and triplet energy transfer processes in the triads will be presented elsewhere).

The observation of a carotenoid cation radical in I has biological relevance in that the formation of a carotenoid cation radical has been observed in photosystem II in certain conditions[27]. Note also that the formation of a carotenoid radical cation in I in organic solvents suggests that charge conduction by a carotenoid through media of low dielectric constant[30] is possible. Furthermore, the observation that an ionic environment promotes the formation of $C^{\cdot+}$–P–$Q^{\cdot-}$ is consistent with the suggestion that specific charged sites on proteins at the reaction centre in photosynthetic membranes may be important in mediating charge separation[31].

The formation of a long-lived charge-separated state from the first excited singlet state of this molecular triad with a reasonable quantum yield has significance for the design of artificial photosynthetic systems. The key to obtaining long lifetimes of the charge-separated state appears to be the interposition of a neutral porphyrin between the widely separated ions, coupled with energetics which are unfavourable for recombination via species such as C–$P^{\cdot+}$–$Q^{\cdot-}$ or $C^{\cdot+}$–$P^{\cdot+}$–Q. Moreover, note that I is relatively stable; there is little change in the sample even after hundreds of laser flashes over several days.

Sensitivity for vertical retinal image differences

Gerald Westheimer

Department of Physiology–Anatomy, University of California, Berkeley, California 94720, USA

The detection of horizontal disparities between the right and left retinal images is accepted as an important component in the visual perception of depth. It has occasionally been pointed out[1–3] that a disparity will also occur in the vertical when a target is nearer to one eye than the other and could be used as a second component[3]. Here it is shown that while it is possible to detect size differences between the retinal images in the vertical direc-

0028–0836/84/070632—03$01.00

© 1984 Macmillan Journals Ltd

tion, the sensitivity is at least one order of magnitude less than the horizontal differences. It had been generally accepted that vertical disparities cannot be detected (literature summarized by Tschermak[4]), but there are clear reports of the ability of subjects to respond to relative differences in the vertical magnification of the images of the two eyes, the so-called induced size effect[2]. It manifests itself in the appearance of a visual scene as if there had been an opposite horizontal magnification and is, therefore, in the correct direction if it is to be utilized in asymmetrical convergence.

Two reasons make it opportune to examine this matter experimentally. Mayhew and Longuet-Higgins[3] have questioned the applicability of recent findings[5,6] which have again failed to show any significant sensitivity of normal observers to imposed vertical disparities in their retinal images. They point out that in actual viewing situations where a target is nearer to one eye than the other, as indeed also in the more artificial conditions for observing the induced size effect, the vertical disparities are appropriately distributed throughout the visual field in a plausible manner. Tests for detection of vertical disparity in a simple unitary target may, therefore, not be successful. The second reason for looking into this matter with some care is the extraordinary sensitivity of most subjects to horizontal disparities. Thresholds of a few seconds of arc indicate that a complex apparatus has to be present to extract this information from the retinal images. Neurophysiological studies of early cortical stages in the mammal indicate disparity coding with at least one and possibly two orders of magnitude less sensitivity[7] and, significantly, the scatter of disparities is about the same in the horizontal and the vertical direction[8,9]. One would thus like to know whether the mechanism for distilling the cortical cells' coarse disparity coding into the fine disparity signals demonstrated in stereoacuity is needed not only in the horizontal direction, but also vertically as would be the case if subjects indeed had good ability to detect vertical disparities, no matter how this ability actually manifested itself.

In the experiments a compromise was struck between the abstract, single feature patterns used in previous disparity detection research and the more variegated visual configurations that seem to be needed to elicit the induced size effect[2]. Five small squares with sides of 5 arc min were seen by both eyes at a distance of 3 m. They were laid out in an inverted V, the middle two squares being 30 arc min apart horizontally and the lower pair 1° apart (Fig. 1). This pattern was chosen because any implicit horizontal disparity induced by vertical magnification[6] would not manifest itself in a tilt of the fronto-parallel plane around a vertical axis, which is the essence of the induced size effect. The rest of the visual field was entirely dark. Because the induced size effect is said to take some time to develop, exposure duration was 1 s, several times longer than needed for good horizotal disparity discrimination.

During an experimental session, the pattern was presented every 3 s and good fixation was maintained in the intervals by showing a fronto-parallel set of four brackets with a central cross, all dimensions being equal in the two eyes. By means of polaroids and a half-silvered mirror it was arranged that one eye saw the display on one oscilloscope and the other eye on another. During each stimulus presentation, the vertical gain of one scope relative to that of the other was set to a value chosen at random from an ensemble consisting of seven gains, for example, 0.94, 0.96, 0.98, 1.00, 1.02, 1.04 and 1.06. That is to say, the whole pattern seen by one eye was 6%, 4%, 2% or 0% larger or smaller vertically than that of the other, randomly chosen for a given presentation. The subject's response was restricted to the decision whether the little squares in the right or left limb of the inverted V configuration were nearer to him. Results (Fig. 1, left), accumulated in several sessions of 300 responses, were fitted by the methods of probits, which enables the identification of a threshold, that is, that image magnification at which the subject on 75% of occasions saw the pattern rotated out of the fronto-parallel plane around a vertical axis in the indicated direction. Thresholds are summarized in Table I for three experienced stereoscopic subjects. Fragmentary results in a fourth subject gave concordant findings. Also shown are the results for equivalent runs in which the magnification changes were given in the horizontal direction, where the situation accurately mimics an actual rotation of the fronto-parallel plane around a vertical axis. Each pair of conditions (horizontal and vertical) is based on a total of 2,000 responses, obtained over several days under strictly comparable conditions.

The findings summarized in Table 1 allow conclusions about both of the questions raised. First, the sensitivity for discrimination of vertical magnification differences in the two eyes is 14, 12 and 3.5 times lower in the three subjects, respectively, than that for horizontal magnification differences. Second, it seems indeed possible to show a small induced effect with appropriate kinds of abstract stimuli: complex patterns, long exposure durations and a relatively conflict-free visual environment seem necessary. Vertical magnification of one eye then produces a restructuring of visual space as if the other eye had been subjected to horizontal magnification. The experiment reported here is, however, not an exact replication of the standard demonstration of the induced size effect[2], where an ink-splattered glass pane is set to appear fronto-parallel by a subject wearing a vertically magnifying lens over one eye.

Succinctly stated, our three subjects viewing a fronto-parallel pattern with a 3% horizontal magnification would call it tilted towards their left on 98%, 99% and 78% of all presentations, respectively; of the presentations with 3% vertical magnification, 58%, 60% and 61% respectively would be called tilted towards their right. The percentages each have a standard error of no more than 3% and even in the second set they are clearly

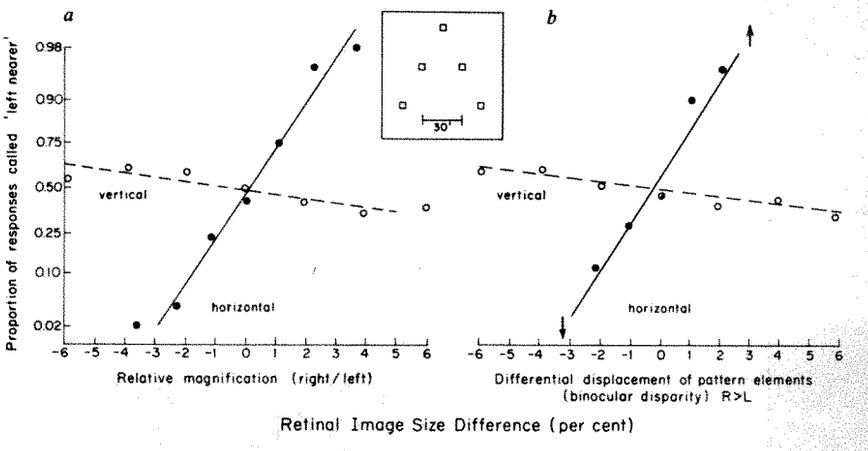

Fig. 1 *a*, Results of 2,000 forced-choice responses from subject G.W., without error feedback, in which right and left retinal images of the pattern seen binocularly (shown in inset) were presented at random with one of the indicated magnification ratios, either horizontally or vertically. *b*, Results of a similar experiment where the pattern elements remained of constant size throughout, but were given differential horizontal or vertical displacements in the two eyes to produce binocular disparities. Lines are best fit probits and allow accurate threshold quantitation: half the image differences for which 75% of the responses are at criterion. Sensitivity for vertical image size differences, whether generated by magnification (*a*) or disparity (*b*), is about an order of magnitude less than for horizontal ones and the responses are of opposite polarity.

Table 1 Threshold difference between subject's right and left retinal images at which he could detect an apparent rotation of a fronto-parallel plane around a vertical axis

Direction	Subject		
	GW	MG	RY
		Magnification	
Horizontal	1.1+0.06	0.9+0.05	2.9+0.2
Vertical*	−12.9+2.3	−12.7+2.7	−10.1+1.8
		Disparity	
Horizontal	0.9+0.06	0.9+0.06	1.5+0.11
Vertical*	−15.5+2.6	−16.9+3.0	−29.3+10.2

Magnification: whole pattern was magnified in the indicated direction-threshold is expressed as per cent magnification (right/left) retinal images. Disparity: pattern elements remained of same size but were differentially displaced in the two eyes to give binocular disparity in the indicated direction, threshold is expressed as per cent difference in target separations in the two eyes.

* The minus sign signifies that the apparent fronto-parallel plane appeared nearer at the subject's right when the retinal image of the right eye was larger vertically than that of the left.

statistically different from random, which would give a 50% response. In a related experiment using gratings with spatial frequency differing in the two eyes, Riguadiere[10] observed much less tilt of the apparent fronto-parallel plane for horizontal than for vertical patterns.

A large difference between horizontal and vertical also showed up when the experiments were repeated with the same geometrical target and exposure duration, but with the depth clue given by pure disparity and not magnification. In practice this meant that the squares making up the target were of identical size in the two eyes under all stimulus conditions, but their relative placements on the two retinas was dictated solely by disparity considerations. This could, however, still be expressed in percentage terms, although now referring to the relative separation of identically sized target elements on the two retinas. The results (Fig. 1, right, and Table 4) confirm the earlier observations of massive differences in sensitivity for horizontal versus vertical disparities[5]. The ratio is about 20 for all three observers.

An induced size effect, therefore, exists not only in the situation used by Ogle, but even here where the experimental situation is governed by the kind of stimulus abstraction commonly used in the psychophysical analysis of the substrates of space perception. The particular patterns in the experiment described here preclude the direct use of implicit horizontal disparity information contained in stimuli with uniocular vertical magnification. This cannot, therefore, be the sole clue for the induced size effect, as has sometimes been thought[5,6].

To see whether there are simple ways of enhancing vertical disparity detection beyond the levels shown in the experiments reported above, two additional factors have been cursorily examined, longer exposure durations and increased pattern size. There was no important change in the threshold when the target was presented for 5 s; and a target consisting of a 7×7 sheet of dots extending over the central 3° of the visual field still did not suffice to lower the disparity threshold materially, so it would appear necessary to postulate spatial integration over a much larger portion of the visual field. If this is the case, we have yet another variable that sets off vertical from horizontal disparity detection, because stereoacuity can be a few seconds of arc for just two small squares separated by 10–20 arc min.

Interspecific chimaerism between sheep and goat

Carole B. Fehilly, S. M. Willadsen & Elizabeth M. Tucker

ARC Institute of Animal Physiology, Animal Research Station, 307 Huntingdon Road, Cambridge CB3 0JQ, UK

In rodents, chimaeric blastocysts produced by combining embryonic cells of two different species have been used in investigations of cell lineage and interaction during development (*Mus musculus–Rattus norvegicus*[1,2], *M. musculus–Clethrionomys glareolus*[3], *M. musculus–Mus caroli*[4]). However, interspecific chimaerism also offers new approaches to the study of reproductive incompatibilities between species and may even allow such incompatibilities to be neutralized, thus improving the chances of successful hybridization and interspecific embryo transplantation[5]. We report here the production of sheep–goat chimaeras by embryo manipulation and the use of interspecific chimaerism to allow successful interspecific embryo transplantation in sheep and goats.

So far, the *M. musculus–M. caroli* chimaeras described by Rossant *et al.*[4–6] seem to be the only viable interspecific mammalian chimaeras to have been produced by embryo manipulation. The two species concerned are closely related and, although they do not normally interbreed, they can be hybridized[7]. The domestic sheep (*Ovis aries*, $2n = 54$) and the domestic goat (*Capra hircus*, $2n = 60$) are less closely related[9,10] but neither a sheep nor a goat has carried a live hybrid fetus to term in a controlled experiment except when special procedures were used to reduce interspecific incompatibility[11]. The rationale of the latter procedures as well as the reproducibility of the results have been questioned[12]. Experimental hybrid pregnancies in both sheep and goat females have often proceeded beyond the time of implantation but, invariably, by the end of the second month the fetus has died[12–14]. The same applies to pregnancies resulting from transfer of sheep embryos to goat recipients, while goat embryos transferred to sheep recipients have not survived beyond the first month[13,15]. The transfer of an embryo belonging to the same species as the recipient together with the foreign embryo does not seem to alter the survival prospects of the latter[15]. In all the above categories of interspecific pregnancies, placental abnormalities, possibly due to maternal immunological reaction against foreign antigens of the conceptus, have been the immediate cause of abortion[16–19].

The present study comprises three series of experiments. In the first series, single blastomeres from 4-cell goat embryos were combined with single blastomeres from 4-cell sheep embryos (Table 1, expt 1*a*), or with single blastomeres from 8-cell sheep embryos (expt 1*b*) in evacuated zonae pellucidae as described by Willadsen[20]. Up to four interspecific embryos of identical composition were made from the same two parent embryos. In the second series of experiments, interspecific 'giant' embryos were produced either by surrounding an 8-cell goat embryo from which the zona pellucida had been removed with the dissociated blastomeres of three 8-cell sheep embryos (expt 2*a*) or by surrounding a similarly denuded 8-cell sheep embryo with the separated blastomeres of three 8-cell goat embryos.

No. of lambs	4	2(?)	1†	0	6	1
No. of kids	0	0	0	1†	1	2
No. of interspecific chimaeras	3	0	2	1	2	0

* As regards embryo composition, $\frac{1}{4}$ represents one blastomere from a 4-cell embryo; $\frac{1}{8}$ represents one blastomere from an 8-cell embryo; and $\frac{8}{8}$ represents all eight blastomeres of an 8-cell embryo. BL, day 8 blastocyst; ICM, inner cell mass and polar trophectoderm from day 8 blastocyst (S, sheep and G, goat).

† Intraspecific chimaera.

The composite embryos in expts 1 and 2 were embedded in agar and cultured in ligated sheep oviducts for 5 (expt 1) or 4 days (expt 2)[20]. They were then examined as fresh specimens (Table 1) and those which had developed into normally organized chimaeric blastocysts were transferred to recipient ewes (expt 1*a* and 2*a*) or recipient goats (expt 1*b* and 2*b*), on day 7 of the oestrous cycle (day of onset of oestrus = day 0).

In a third series of experiments, the inner cell mass and polar trophectoderm from day 8 goat blastocysts were inserted into day 8 sheep blastocysts by the technique described by Gardner[21] (expt 3*a*). In the same way, sheep inner cell masses and polar trophectoderm were combined with goat blastocysts (expt 3*b*). The blastocysts were transferred to sheep (expt 3*a*) or goat recipients (expt 3*b*) on day 8 of their oestrous cycle.

The main results of the experiments are presented in Table 1. The proportion of composite embryos which formed normally organized blastocysts during culture *in vivo* was somewhat lower than that observed in parallel experiments on intraspecific chimaerism in sheep, but judged by the initial pregnancy rate obtained after transplantation of interspecific blastocysts, they were as viable as intraspecific embryos of the same cell number, whether chimaeric or non-chimaeric. However, one pregnancy failed at about day 60, and two fetuses were aborted near term in expt 1*a*.

The seven full-term young (and the two aborted fetuses) in expt 1*a* all had the general appearance of lambs, but in three of these animals the fleece had transverse bands and patches of hair contrasting sharply with the surrounding densely curled wool (Figs 1, 2). Two of these animals each had a twin, produced from the same two parent embryos. Both of the respective twins were lambs with ordinary fleeces. The hairy bands were therefore thought to represent goat tissue, and the three animals were judged to be overt sheep–goat chimaeras (Fig. 3). The two young in expt 1*b* both looked like ordinary lambs; both were stillborn. The three young produced in expt 2*a* also had the general appearance of lambs, but two of these had hairy bands and patches in their fleeces similar to those observed in three of the lambs in expt 1*a*. These two lambs, which were dead at delivery, were therefore also judged to be overt sheep–goat chimaeras. They had developed from a single 'giant' blastocyst. Both of the young produced in expt 2*b* were of the same general appearance as ordinary kids. However, in one of them (Fig. 4) the normal straight goat hair was replaced by densely curled wool in symmetrically situated areas on the neck, shoulders and thighs. The wool was thought to be of sheep origin, and the animal was therefore judged to be an overt sheep–goat chimaera.

Fig. 1 Sheep–goat chimaera (standing) and its sheep twin (see expt 1*a* of Table 1). The two animals, both phenotypically male, developed from chimaeric embryos which shared both their sheep (Suffolk × Welsh Mountain) and their goat (Nubian × Saanen) parent embryo, and were, therefore, monozygotic twins with respect to their sheep component. Note the hairy bands and patches on the neck and trunk of the chimaera. Apart from the white patches on the legs (and ears) the pattern of pigmentation in the chimaera did not differ from that seen in its sheep twin, although the colours were brighter in the hairy areas than in the woolly areas.

Fig. 2 Dorsal view of another sheep–goat chimaera from expt 1*a*. Note the essentially asymmetric distribution of the relatively narrow hairy bands and patches along the midline. The type of fibre (wool or hair) produced in the epidermis is determined by the origin of the underlying dermis (sheep or goat) thus chimaerism, as observed at this stage, had its basis in mesodermally rather than ectodermally derived tissues, despite the absence of blood chimaerism. The pattern of distribution of the hairy bands is of somatic origin.

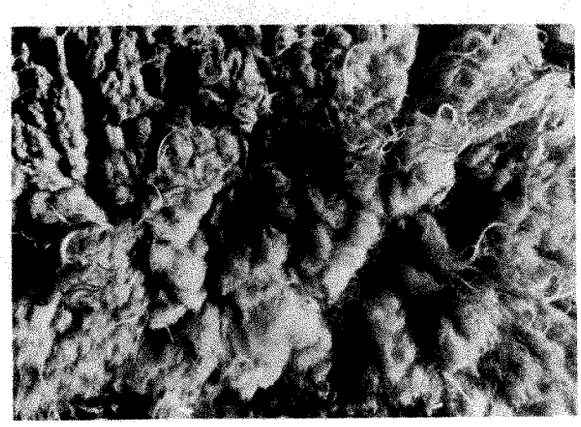

Fig. 3 Close-up of the back of a $1\frac{1}{2}$ yr-old sheep–goat chimaera. By now the wool fibres have outgrown the hair fibres in the fleece so that the hairy bands and patches, although still clearly demarcated, are less conspicuous. Note that two types of fibres can be distinguished within the woolly areas: densely curled fibres of the type normally seen in Suffolk × Welsh Mountain sheep constitute the bulk of the fleece, but in addition there are tufts of longer, wavy (goat wool) fibres, which form a smaller proportion of the fleece but occur throughout. The presence of two types of wool fibres indicated chimaerism in ectodermally derived tissues in addition to the chimaerism in mesodermally derived tissues reflected in the presence of the hairy bands. The latter probably consist mainly of sheep hair but with tufts of goat hair interspersed.

Fig. 4 Sheep–goat chimaera from expt 2*b* at 1 yr old. In this animal many chimaeric features are evident, of which the strongly curved goat horns and the large patches of long, wavy (goat) wool are the most obvious. The distribution of wool, interesting by being essentially symmetric, coincides with areas of the epidermis overlying dermis derived from the lateral mesoderm. The animal, which contains both a male sheep and a male goat component, behaves like a male goat but has proved infertile in natural matings with female goats. The semen is of normal density, but almost all the spermatozoa have a characteristic tail defect.

Six of the nine young produced in expt 3*a* looked in every respect like ordinary lambs. Of the remaining three, one was similar to the chimaeric lambs in expt 1*a*, and another was similar to the chimaeric kid in expt 2*b*, except that its skin had transverse bands and patches of wool along the back; both of these animals were judged to be overt sheep–goat chimaeras. The last of the three animals produced in expt 3*a* looked in every respect like an ordinary kid. Two of the three young produced in expt 3*b* resembled ordinary kids, but the third, which was born as a twin to one of the kids, looked like a lamb.

Blood samples from those lambs and kids which were born alive were tested with respect to the following proteins which differ electrophoretically between sheep and goat[22]: haemoglobin (adult and fetal), carbonic anhydrase, nucleoside phosphorylase, X-protein, malic enzyme, NADH diaphorase and transferrin. The only animal in which interspecific blood chimaerism was demonstrated was the overtly chimaeric kid in expt 2*b*, in which both parent species were represented in all blood proteins tested. The other overt chimaeras all had sheep-type blood proteins, while the remaining animals, including the kid in expt 3*a* and the lamb in expt 3*b*, had blood proteins entirely of the type corresponding to their species of physical appearance.

Thus, the present experiments show that sheep and goat blastomeres can form composite blastocysts and that such interspecific blastocysts are, in principle, viable and may give rise to animals which are sheep–goat chimaeras. In addition, the experiments have shown that a goat fetus can develop to term in a sheep and, similarly, that a sheep fetus can develop to term in a goat. In expt 1*a* the high abortion rate, the relatively low incidence of chimaeras among the offspring, and the disproportionately large contribution made by the sheep blastomeres even in those animals which were overt sheep–goat chimaeras, probably all reflect a reaction on the part of the recipient ewes against the goat component of the conceptus. Although intraembryonic incompatibility or competition between the two species may also have influenced the results, this is less likely to have been the principal cause of the predominance of the sheep component since extensive interspecific chimaerism was observed in one animal in expt 2 and in another in expt 3. The results of the latter experiment indicate that in sheep and goats it is possible to completely neutralize incompatibility between the conceptus and the recipient female by constructing the chimaeric embryo in such a way that the trophectoderm and hence the chorionic epithelium consists entirely of cells belonging to the same species as the recipient. It is probable that the low rate at which this was achieved reflects inadequacy of the particular approach used in that experiment. The results of expt 1*b*, although incomplete, suggest that a more economical and practical way of achieving the same objective is the use of asynchronous parent embryos and reduction of the total cell number to near the minimum required to form a normally organized blastocyst. This is in agreement with the observation made in experiments on intraspecific chimaerism in sheep (C.B.F. and S.M.W., unpublished observations).

We thank Miss S. Clarke for help with the bloodtyping and Dr A. Dain for karyotyping blood lymphocytes of the animal in Fig. 4. C.B.F. was supported by Research Studentships from the MRC and Trinity College, Cambridge.

Experimental chimaeras—removal of reproductive barrier between sheep and goat

Sabine Meinecke-Tillmann

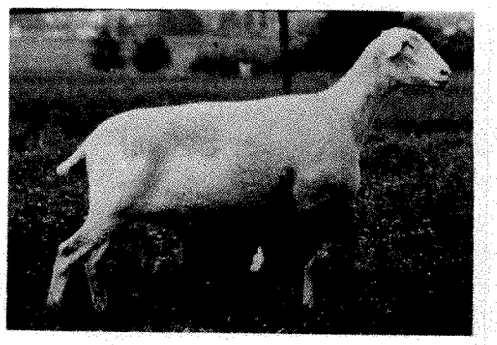

Fig. 1 Male goat–lamb by a Merino mother.

Following reciprocal embryo transfer between sheep and goats, the embryo of the foreign species is able to induce early pregnancy but the embryos do not survive beyond the first weeks of gestation[1,2]. Similar results have been obtained from hybridization experiments on sheep and goats. While the causes for early embryonic death of hybrid eggs from donor sheep are unknown, the reciprocal event has been associated with immunological implications[2–7]. As a means of overcoming the reproductive barrier between sheep and goats, we have transferred interspecific chimaeric embryos. We report here the birth of a goat kid from a sheep mother.

Following oestrus synchronization and natural breeding, embryos were collected from super-ovulated donors on day 2 of pregnancy in sheep (onset of oestrus = day 0) and on day 3 of pregnancy in goats (second day of oestrus = day 0). The chronological difference between the embryos of the two species was about 24 h.

To produce interspecific chimaeric embryos we combined one sheep blastomere of the 4-cell stage with two goat blastomeres of the 8-cell stage, or two sheep blastomeres of the 'early' 8-cell stage with two goat blastomeres of the 'late' 8-cell stage in a common pig zona pellucida. To prevent wastage of cells the slit in the first zona pellucida was completely covered by a second one which surrounded the aggregated embryo with its first host zona. Micromanipulation was done as described previously[8].

The embryos were then transferred to the oviducts of an intermediate recipient and were recovered again when blastulation was expected. Embryos which reached the blastocyst stage were transferred to the uterine horns of the final sheep recipients. Diagnosis of pregnancy was by radioimmunological measurement of plasma progesterone in the recipients on day 18 and 50 of pregnancy.

The results of the experiments are summarized in Table 1. Of 15 interspecific chimaeric embryos analysed after recovery from the intermediate recipients, 9 had developed into a common blastocyst. Of four further embryos which reached the blastocyst stage, one blastomere of the aggregate did not continue to cleave, and in two cases two small blastocysts instead of one developed in their common zona pellucida.

Of 15 final recipients 8 did not return to oestrus and early pregnancy was confirmed by radioimmunoassay. The remaining seven animals returned to oestrus between day 21 and 36 but in all of the cases except one the plasma progesterone values were well above 2 ng ml^{-1} on day 18. On day 50 plasma progesterone was above 2 ng ml^{-1} in six animals.

Three recipients went to term and gave birth to two sheep– and one goat–lamb (Fig. 1). One of the sheep lambs was stillborn because of delayed parturition. The stillborn male sheep–lamb was derived from a combination of two sheep and two goat blastomeres, but in the common blastocyst one goat blastomere was not integrated. The female sheep–lamb was born after transfer of two blastocysts in one common zona pellucida. The goat–lamb developed after aggregation of one blastomere of a 4-cell sheep embryo and two blastomeres of an 8-cell goat embryo. All blastomeres had participated in the development of the common blastocyst.

Table 1 Development of interspecific chimaeric embryos

		Development after transfer to intermediate recipients			Development after transfer to the final recipients			
	Type of chimaeric embryo*	Common blastocyst	Blastocyst (one original blastomere did not cleave)	Two separate blastocysts	Plasma progesterone (ng ml^{-1}) day 18	day 50	Return to oestrus	Delivery

Cytogenetic analysis, haemoglobin and transferrin typing, blood group serology, polyacrylamide gel electrophoretic analysis of blood and muscle proteins and breeding experiments gave no indications of chimaerism.

Thus, by micromanipulation it is possible to overcome the reproductive barrier between sheep and goats, but only when there is a protective mechanism which prevents recognition of the foreign fetus by the mother of the other species. It is assumed that at least the important parts of the placenta, particularly the chorion epithelium, which developed from the trophoblast of the chimaeric blastocyst, were derived from the sheep blastomere, and that the sheep trophoblast components were able to protect the goat embryonic cells from maternal immune rejection. This has been accomplished by combining chronologically different blastomeres. In the embryo which is formed, the younger component tends to give rise to the extra-embryonic membranes and the older component to the fetus. Recent reports on developmental potential of sheep blastomeres[9] and interspecific mouse chimaeras[10] confirm these concepts. Equally, the experiments of S. M. Willadsen and C. B. Fehilly (personal communication) which resulted in the birth of sheep–goat chimaeras revealed the importance of constructing embryos so that the outside cells belong to the species into which the embryos have been transferred. Also, the endocrinological status indicates the sheep origin of the trophoblast. It is known that the goat placenta is not a source of progesterone as the sheep placenta is. After day 55 of pregnancy in sheep the survival of the fetus depends on proper progesterone production by the placenta[11].

The technique described here could be useful for rescuing endangered species.

We thank Dr Glahn-Luft, Dr Heinert, Dr Höhn and Professor Schmid for their technical assistance. This study was supported by a grant from the Deutsche Forschungsgemeinschaft.

An antigenic difference between cells forming early and late haematopoietic spleen colonies (CFU-S)

R. A. Harris*, P. M. Hogarth†, L. J. Wadeson*, P. Collins†, I. F. C. McKenzie† & D. G. Penington*

* University of Melbourne Department of Medicine, St Vincent's Hospital, Fitzroy, Victoria, Australia 3065

Murine pluripotent haematopoietic stem cells have generally been assayed by their ability to form macroscopic colonies of haematopoietic cells in the spleens of heavily irradiated recipient mice (colony-forming unit-spleen or CFU-S assay)[1]. However, recent evidence suggests that there are distinct subpopulations of CFU-S[2]. Most spleen colonies present 7–8 days after injection consist of differentiated erythroid cells, contain no primitive myeloid or erythroid precursor cells and disappear from the spleen within 3 days, whereas the majority of colonies present at 10–12 days contain primitive precursors, are multilineal and cannot be detected at 7–8 days[2]. Furthermore, many 10-day-old spleen colonies do not contain cells capable of forming spleen colonies in secondary irradiated recipients (an index of the self-renewal capacity of stem cells) whereas at day 14 almost all colonies contain these CFU-S[3]. These studies suggest that only when colonies are scored at or later than 11–12 days is the spleen colony technique adequate for the assay of multipotential stem cells. We now report an antigenic difference between subpopulations of CFU-S forming early (day 8) and late (day 14) spleen colonies which has been used to purify multipotential haematopoietic stem cells from murine bone marrow.

A cytotoxic IgG2b monoclonal antibody to a 'Qa-2 like' alloantigen, Qa-m2 (ref. 4), reacts with a minority (~10–15%) of bone marrow cells[4] (mostly lymphocytes[5]) and has been shown to kill, in the presence of complement, megakaryocyte colony-forming cells (MEG-CFC) but not granulocyte-macrophage (GM-CFC) or 7-day erythroid colony-forming cells (E-CFC)[5]. These experiments were extended to investigate whether more primitive haematopoietic cells (that is, CFU-S) express Qa-m2. Treatment with anti-Qa-m2 and complement had no effect on the capacity of C57BL/6 bone marrow cells to form spleen colonies 8 days after injection into irradiated hosts (Table 1). However, spleen colony-forming ability was progressively inhibited at later time points. By day 14, spleen colony numbers were reduced by 82% compared with the number formed by cells treated with a negative control antibody, anti-Ly-2.1 (ref. 6), and complement. In contrast, treatment with monoclonal anti-H-2.2 and complement (positive control) abolished colony formation at all times. These results suggest progressive loss of Qa-m2 expression with differentiation from more primitive multipotential cells (day 14 CFU-S) to those with restricted potential (day 8 CFU-S).

Since the CFU-S assay may not adequately predict the capacity of haematopoietic tissue to repopulate the bone marrow of lethally irradiated recipients[7], the effect of anti-Qa-m2+C on this property was studied (Table 2). Anti-Qa-m2+C

Table 1 Effect of anti-Qa-m2 and complement (C) on spleen colony formation at various times after injection of bone marrow cells

Days after injection of cells	CFU-S/1×10^5 marrow cells*			% Reduction by anti-Qa-m2 +C (no. of experiments)†
	Anti-H-2.2 +C	Anti-Ly 2.1 +C	Anti-Qa-m2 +C	
8	0	22.4±3.0	21.1±2.9	7 (5)
10	0	19.6±2.0	15.5±2.3	20 (3)
11	0.2±0.4	19.3±1.2	10.8±1.0	44 (2)
12	0.3±0.5	15.3±2.1	4.2±2.6	71 (3)
14	0	18.6±2.8	3.1±2.0	82 (4)

C57BL/6 bone marrow cells (2×10^6) in 0.1 ml HEPES-buffered alpha medium with 10% heat-inactivated fetal calf serum (FCS) were incubated with monoclonal anti-Qa-m2 (serum from hybridoma-bearing mice, final dilution 1:100), monoclonal anti-H-2.2 serum (1:100 dilution, positive control) or monoclonal anti-Ly-2.1 serum[6] (1:100 dilution, negative control) for 30 min on ice. The concentration of anti-Qa-m2 serum used was >1,000-fold greater than that required for maximal lysis of MEG-CFC[5]. The cells were washed, resuspended in 0.4 ml absorbed rabbit serum (diluted 1:8) as a source of complement (C), and incubated at 37 °C for 45 min. The cells were washed in phosphate-buffered saline (PBS) and injected into groups of 7–10 syngeneic irradiated (825R) specified-pathogen free recipients. From 3×10^4 (for day-14 colonies) to 1×10^5 cells (day-8 colonies) were given to each mouse. At the indicated times after injection, mice were killed by cervical dislocation. Their spleens were removed, fixed in Bouin's fixative, and surface macroscopic colonies were counted.

* Results from a typical experiment (mean ± 1 s.d.).

† Comparison is with anti-Ly-2.1+C-treated cells (negative control). Mean per cent reduction from indicated number of experiments (in parentheses) is shown. The spleens of uninjected irradiated control mice contained <1 colony per 10 spleens at each time point. Treatment of C57BL/6 bone marrow cells as described above produced 9.8±3.2% (mean±s.d.) lysis of anti-Qa-m2+C treated cells compared with 7.3±2.1% lysis after treatment with anti-Ly-2.1+C (three experiments)[5].

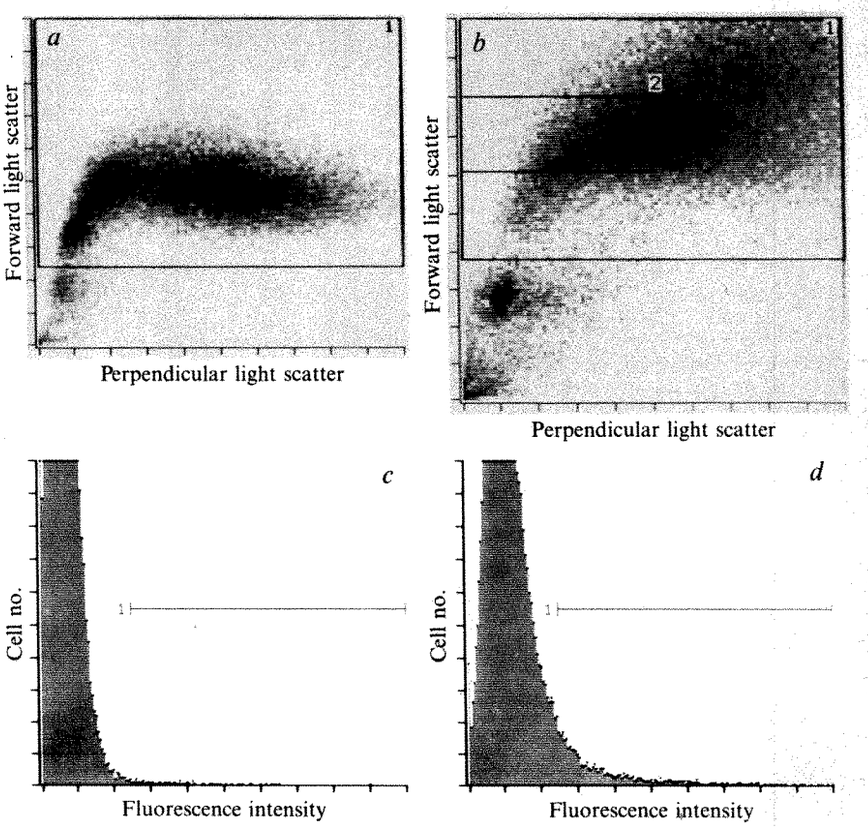

Fig. 1 *a*, Cytogram of lymphocyte-depleted normal marrow cells according to forward and 90° light scatter characteristics. *b*, Cytogram of 5FU8BM cells similarly analysed. *c*, *d*, Examples of fluorescence-intensity profiles for cells in region 2 of 5FU8BM: *c*, treated with anti-Ly-2.1 (negative control) and *d*, treated with anti-Qa-m2. The horizontal bar indicates the region in which cells were sorted as Qa-m2$^+$.

Methods: Normal C57BL/6 bone marrow cells (NBM) or marrow cells from mice treated 8 days previously with 5-fluorouracil (150 mg kg^{-1} intravenously) and endotoxin (*Escherichia coli* 0111:B4 (Difco), 6 μg per mouse intraperitoneally) (5FU8BM) were depleted of lymphocytes, red cells and dead cells as described[5]. Briefly, marrow cells were treated with monoclonal anti-Thy-1.2 serum (1:100 dilution), washed, rosetted with sheep red blood cells coupled with sheep anti-mouse Ig, and depleted of rosetted lymphocytes (T and B), red cells, dead cells and some neutrophils by centrifugation through an Isopaque–Ficoll gradient (ρ 1.090 g cm^{-3})[5]. The lymphocyte-depleted marrow interface cells were treated with anti-Qa-m2 serum (1:100 dilution) for 30 min on ice, washed three times and developed for indirect immunofluorescence by incubating with fluorosceinated F(ab^1)$_2$ goat anti-mouse IgG (Cappel Laboratories) (1:20 dilution) for 30 min on ice. Cells were washed and suspended in phosphate-buffered saline containing 1% bovine serum albumin and 0.02% sodium azide before analysis and sorting on an Ortho Cytofluorograph System 50L cell sorter. Unsorted and sorted fractions were assayed for their content of day-8 and day-14 CFU-S in lethally irradiated syngeneic recipients (Table 1). Cells were sorted on the basis of fluorescence only in large rectangular windows (region 1) in *a* and *b* (that is, gating out only dead cells which fluoresce non-specifically) or by three-parameter sorting by selecting fluorescent cells in a region (region 2 in *b*) enriched for CFU-S in 5FU8BM by light scatter (forward and 90°) characteristics, based on preliminary experiments (unpublished). Background fluorescence (that is <0.5% of cells) in each region was set using an aliquot of lymphocyte-depleted marrow cells (NBM and 5FU8BM) treated with anti-Ly-2.1 serum (negative control, 1:100 dilution) but otherwise treated as above. Anti-Qa-m2-treated cells with fluorescence intensity greater than background in each region were sorted as Qa-m2$^+$ and the remainder of cells in each region sorted as Qa-m2$^-$.

treatment significantly reduced the ability of bone marrow cells to reconstitute haematopoiesis, as measured by platelet counts, marrow cellularity and the femoral content of MEG-CFC and GM-CFC in recipients 14 days after injection of cells. Since anti-Qa-m2 with complement has no significant direct cytotoxic effect on GM-CFC or E-CFC (ref. 5), the reduction in marrow reconstituting ability probably reflects complement-mediated lysis of more primitive multipotential cells (such as day 14 CFU-S or 'pre-CFU-S'[7]) which generate these committed progenitor cells. The smaller reduction in repopulation indices (~50%) compared with reduction of day 14 CFU-S (~80%, Table 1) produced by anti-Qa-m2 and complement probably reflects incomplete regeneration from residual undamaged primitive precursors over the 14-day assay period.

As most C57BL/6 bone marrow cells are Qa-m2$^-$ (refs 4, 5) the anti-Qa-m2 antibody was used to separate subpopulations of CFU-S and to purify day 14 CFU-S from bone marrow by indirect immunofluorescence using a cell sorter (Fig. 1, Table 3). All T-lymphocytes and ~25% of B-lymphocytes in C57BL/6 mice are Qa-m2$^+$ (ref. 4). Therefore normal bone marrow was first depleted of lymphocytes (plus erythrocytes, dead cells and some neutrophils) using a rosetting procedure (ref. 5 and Fig. 1). The lymphocyte-depleted bone marrow cells contained >80% of day 8 and day 14 CFU-S (Table 3). The cells in this fraction were treated with anti-Qa-m2 and stained by indirect immunofluorescence. Viable cells were sorted into Qa-m2$^+$ and Qa-m2$^-$ fractions using lymphocyte-depleted marrow cells treated with a negative control antibody to set background fluorescence (Fig. 1). The Qa-m2$^+$ fraction (~3% of unfractionated marrow cells) contained 65% of sorted day 14 CFU-S (representing 15-fold enrichment compared with unfractionated marrow) but only 6% of sorted day 8 CFU-S (1.6-fold enriched) most of which were Qa-m2$^-$ (Table 3).

To further purify day 14 CFU-S, we used bone marrow obtained from mice treated 8 days previously with 5-fluorouracil (a cycle-active drug which preferentially kills proliferating cells) and endotoxin (which enhances marrow recovery[8]) (Fig. 1). This regenerating marrow (5FU8BM) contains supranormal numbers of CFU-S (ref. 8) and is enriched for these cells (Table 3). As found with normal marrow, >80% of day-8 and day-14 CFU-S were recovered in the lymphocyte-depleted 5FU8BM fraction. Single parameter (Qa-m2$^+$ fluorescence) sorting of viable lymphocyte-depleted cells resulted in 15-fold enrichment for day-14 CFU-S. However the fluorescent Qa-m2$^+$ fraction contained only 39% of sorted day-14 CFU-S (and <1% of sorted day-8 CFU-S) (Table 3). The reason for the smaller proportion of day-14 CFU-S in the Qa-m2$^+$ cell fraction from regenerating marrow compared with normal marrow is not known. It is possible that Qa-m2 expression by these cells may be related to their cell-cycle status. We are currently investigating this possibility. Based on prior studies of the light-scattering characteristics of CFU-S in 5FU8BM (unpublished observations), fluorescent (Qa-m2$^+$) cells were selected in a region gated according to forward and perpendicular light scatter (Region 2, Fig. 1*b*). This fraction was further enriched for day-14 CFU-S (to ~30-fold) but not for day-8 CFU-S, and contained 73% of the Qa-m2$^+$ day-14 CFU-S (24% of initial) (Table 3). The final recovery of day 14 CFU-S in this fraction was ~15–20% of the initial day 14 CFU-S in unfractionated 5FU8BM after all fractionation procedures (after taking into account losses of cells during sorting, washing and so on).

The 24-h spleen-seeding efficiencies (f) of day-8 and day-14 CFU-S in 5FU8BM, determined as described[3,9,10], were 0.03 and 0.035, respectively. The corresponding values for 2-h f were 0.09 and 0.106. If, as seems likely[11], f is the same for enriched populations of CFU-S as for those in unfractionated marrow

Table 2 Effect of anti-Qa-m2 and complement (C) on capacity of bone marrow cells to reconstitute haematopoiesis in lethally-irradiated mice

Treatment of cells	Day-14 post-825 rad: Platelet count ($\times 10^9$/l)	Viable nucleated cells per femur ($\times 10^{-6}$)	GM-CFC per femur ($\times 10^{-3}$)	MEG-CFC per femur ($\times 10^{-2}$)
Anti-Ly-2.1+C (1×10^6 cells per mouse)	335±27 (10)	14.1±2.5 (10)	8.7±2.1 (10)	6.0±1.2 (10)
Anti-Qa-m2+C (1×10^6 cells per mouse)	162±15 (10)	7.3±1.3 (10)	3.8±1.0 (10)	3.1±0.8 (10)
Radiation control (no cells)	40±3 (5)	1.2±0.3 (5)	0 (5)	0 (5)

C57BL/6 bone marrow cells were treated with anti-Qa-m2+C or anti-Ly-2.1 (negative control antibody)+C as described (Table 1) and injected into irradiated (825R) syngeneic hosts (1×10^6 cells per mouse). Fourteen days later, mice injected with cells and radiation controls receiving no cells were bled from the retroorbital plexus, then killed by cervical dislocation. Cells were obtained from the femurs of individual mice, counted, and assayed for megakaryocyte colony-forming cells (MEG-CFC) and granulocyte-macrophage colony-forming cells (GM-CFC) as described[5]. Femoral CFC content was calculated from the mean of four replicate culture plates per individual mouse cell suspension. Platelets were counted by phase microscopy. Results (mean ± 1s.e.m.) of a single experiment are shown. The numbers in parentheses indicate number of mice. Similar results were obtained in two additional experiments.

Table 3 Separation of CFU-S populations and enrichment for day-14 CFU-S using monoclonal anti-Qa-m2 and cell sorting

Cell fraction	Normal bone marrow: Initial viable cells %	CFU-S per 1×10^5 cells: Day 8	Day 14	5FU8 bone marrow: Initial viable cells %	CFU-S per 1×10^5 cells: Day 8	Day 14
Unfractionated unsorted marrow	100	17.4	18.5	100	97	110
Lymphocyte-depleted marrow	57	27.2	27.9	45	179	206
Qa-m2$^-$ viable cells (region 1, Fig. 1*a* and *b*)	53.7	25.9	9.8	42.8	172	111
Qa-m2$^+$ viable cells (region 1, Fig. 1*a* and *b*)	3.3	28.5	285	2.2	32	1,660
Qa-m2$^+$ cells selected by scatter characteristics for CFU-S (region 2, Fig. 1*b*)	ND	ND	ND	0.8	75	3,250

Bone marrow cells (NBM or 5FU8BM) were depleted of lymphocytes, treated with anti-Qa-m2, developed for indirect immunofluorescence, and sorted on the basis of fluorescence only (region 1) or by three parameter sorting (that is, forward and perpendicular light scatter characteristics and fluorescence (region 2)) as described (Fig. 1). The relative proportions of CFU-S in the various fractions (per cent of initial unfractionated unsorted marrow) were determined by multiplying the number of CFU-S per 1×10^5 cells by the proportion of viable cells in that fraction and dividing by the frequency of CFU-S in unsorted unfractionated marrow (for results see text). Results are typical of 3–6 similar experiments. ND, not determined.

and the 2-h *f* values are used, then at least 30% of cells in the most highly enriched fraction of 5FU8BM are day-14 CFU-S and ~0.8% are day-8 CFU-S. However, if the more generally accepted[9,10] 24-h values for *f* are used, ~90% of these cells are day-14 CFU-S (and ~2% are day-8 CFU-S). More than 98% of the cells in this fraction were undifferentiated mononuclear cells with moderately high nucleus-cytoplasm ratio, immature chromatin pattern, several nucleoli and agranular basophilic cytoplasm. Culture of these cells in agar[5] showed that ~5% were MEG-CFC, ~1–2% were GM-CFC and 2–3% were mixed E-CFC. Thus, highly purified multipotential stem cells (day-14 CFU-S), separated from the bulk of day-8 CFU-S, committed progenitor cells and other marrow cells, were obtained with reasonable yield from 5FU8BM.

Our results clearly demonstrate an antigenic difference between functionally distinct subpopulations of CFU-S, and strongly suggest that Qa-m2 is, or is part of, a differentiation antigen for multipotential haematopoietic stem cells. An intriguing but as yet untested possibility is that the Qa-m2 determinant may play a functional role in haematopoietic differentiation. Previous studies[5] and studies in progress (unpublished observations) indicate that differences in Qa-m2 expression can be used to separate MEG-GFC and mixed erythroid-CFC (Qa-m2$^+$) from GM-CFC and 7-day E-CFC (Qa-m2$^-$) suggesting that the former two types of CFC are more closely related to the multipotential stem cell than the latter committed progenitor cells. Thus the anti-Qa-m2 antibody should be a valuable tool for investigating the earliest steps in haematopoietic differentiation, including the order of restriction of potentialities in stem cell progeny[12]. Highly purified multipotential stem cells, obtained as described here, will be useful in investigation of the process of commitment to a line of differentiation, and in exploring the relationship between CFU-S and other primitive haematopoietic cells[7,13,14]. However, as day-14 CFU-S in 5FU8BM may have properties different from those in unstimulated normal bone marrow, we are currently attempting to further purify these cells from normal marrow using density gradients[15] and depletion of mature marrow cells with monoclonal antibodies[16] before cell sorting.

We thank Dr G. S. Hodgson for helpful advice. This work was supported by the National Health and Medical Research Council of Australia.

Glial heterogeneity may define the three-dimensional shape of mouse mesencephalic dopaminergic neurones

S. Denis-Donini*, J. Glowinski & A. Prochiantz

Groupe NB, INSERM U.114, Collège de France, 11 place Marcelin Berthelot, 75231 Paris Cedex 05, France

The shape of a neurone—the projection and branching pattern of axons and dendrites—appears to be determined by a combination of intrinisic and environmental influences[1–5]. We have previously shown that striatal target neurones influence the biochemical maturation of ascending mesencephalic dopamine (DA) cells in culture[6,7], as well as the elongation rate of DA neurites[8]. Using a similar approach in which the morphology of individual DA cells can be studied after ^{3}H-DA uptake and autoradiography, we now report on *in vitro* neurone-glia interactions and show that glial cells exert a morphogenetic effect on DA neurones. Dopaminergic neurones from the mesencephalon were plated on glial monolayers prepared either from the striatal or the mesencephalic region of the embryonic brain. On mesencephalic glial cells the majority of DA neurones develop a great number of highly branched and varicose neurites, whereas on striatal glia they only exhibit one long, thin and rather linear neurite. These results demonstrate that glial cells from two different brain regions have distinct properties which could be used to define neuronal polarity observed *in vivo*.

Cultures of glial cells from mouse embryos were generated from the mesencephalon (ED 13) and the striatum (ED 15) and grown for 3 weeks as described in detail in Fig. 1 legend. In such cultures, most neurones have died and the non-neuronal cells form a confluent monolayer (Fig. 3). Indeed autoradiography after ^{3}H-DA uptake or immunocytochemistry after incubation with an antibody against the 70 K subunit of the neurofilament triplet did not reveal the presence of surviving neurones. Mesencephalic cells (ED 13) containing a subpopulation of DA neurones were plated on these preformed monolayers and their morphology was examined after 1, 2, 3 and 10 days in culture following ^{3}H-DA uptake and autoradiography. Already after 1–2 days in culture DA neurones grown on glial cells from these two brain areas exhibit strikingly different morphologies. On a glial monolayer generated from the striatum, most cells are either ovoid or multipolar as described *in vivo* and *in vitro*[9–11], they usually extend one long linear process at one pole and one or a few shorter ones at the opposite pole or around the cell soma. This type of morphology is illustrated in Fig. 1*a* in which four cells have been photographed. However, when grown on a glial monolayer originating from the mesencephalon they have a great number of highly branched smooth or varicose processes (Fig. 1*b*). Figure 2 shows the differences in the morphology of DA neurones observed in both culture conditions. The number of neurites on glial mesencephalic monolayers as well as their thick varicose aspect has led us to call them 'highly branched' processes. In contrast, the thin and almost unique neurite that elongates on striatal glial cells will be called 'poorly branched'. Similar results were obtained when DA neurones were identified by immunocytochemistry using an antibody against tyrosine hydroxylase.

As already pointed out this dramatic difference between the morphologies of DA cells is clearly visible as early as one day after the beginning of the culture. Table 1 shows the number of neurones displaying one or the other configuration after various times in culture. Since in both culture conditions a small constant number (15%) of DA cells does not extend any neurite, we have only included neurites displaying cells in this table. The data show that the number of labelled DA neurones is identical after 2 days in culture on both monolayers. It slightly increases after 3 days probably because some neurones had not yet acquired the capacity to take up the neurotransmitter after 2 days *in vitro*. After 10 days, the number of surviving neurones is lower on both glial monolayers. The percentage of DA neurones presenting a 'highly branched' arborization remains constant on mesencephalic glial monolayers (60, 74 and 54% at 2, 3 and 10 days respectively). This is not the case on striatal glial monolayers, since, although 100% of the neurones develop one long neurite after 2 and 3 days *in vitro*, after 10 days this percentage falls to 34%, and 66% exhibit 'highly branched'

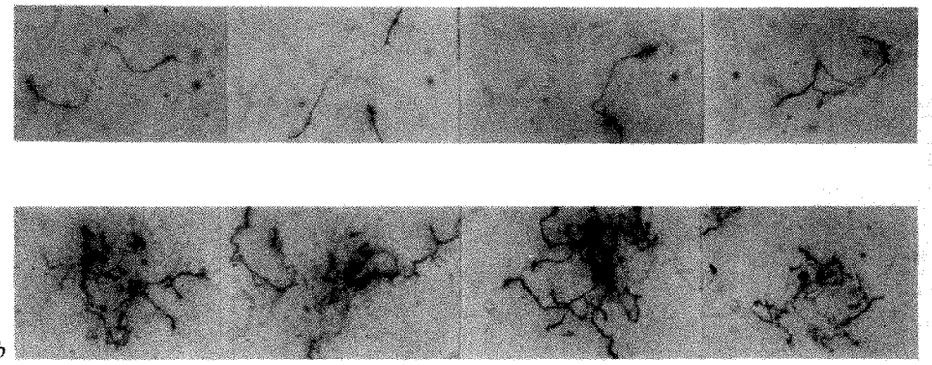

Fig. 1 *a*, Visualization of four dopaminergic neurones after 2 days *in vitro* on a monolayer of striatal glial cells (×46). *b*, Visualization of four dopaminergic neurones after 2 days *in vitro* on a monolayer of mesencephalic glial cells (×46).
Methods: Cells from the mesencephalon and the striatum of 13- and 15-day-old Swiss mouse embryos were prepared as already described[6–7], and plated at the concentration of 10^6 cells per dish in Falcon dishes coated with polyornithine (Sigma, 40,000 MW, 1.5 μg ml^{-1}). Glial monolayers were obtained by culturing the cells for 3 weeks in nutrient mixture F12, minimum essential medium (Gibco, 1:1) complemented with 10%-inactivated fetal calf serum (Serumaid), 3.3×10^{-2} M glucose, 2×10^{-3} M glutamine and 0.3×10^{-2} M sodium bicarbonate. The culture medium was not changed for 1 week and then changed 3 times a week. Freshly dissociated rostral mesencephalic 13-day-old embryonic cells (5×10^5 to 10^6) were seeded on these monolayers and the culture was pursued for 2 more days. Dopaminergic neurones were examined by autoradiography. Cells were incubated at 37 °C for 1 h with 5×10^{-7} M ^{3}H-DA (6 Ci mmol^{-1}, NEN) in 1-ml phosphate buffer supplemented with 10^{-3} M magnesium, 10^{-3} M calcium and 3.3×10^{-2} M glucose (PBS). After three washes with cold PBS, the cells were fixed for 1 h at room temperature with 1.5% glutaraldehyde (Taab Laboratories) in PBS, washed four times with PBS, air dried and covered with Kodak NTB2 emulsion. Autoradiograms were developed 2 weeks later using Kodak Dektol. No labelling was seen when the cells were incubated in the presence of 5×10^{-6} M benztropine (Merck), a potent inhibitor of ^{3}H-DA uptake into dopaminergic neurones.

processes. The *in vitro* development of mesencephalic glial cells seeded together with the neurones could provide an explanation for this observation.

Since glial monolayers are important in neuronal morphogenesis, we analysed their cellular composition by immunocytochemistry using an antibody against the glial fibrillary acidic protein (GFAP), a specific marker for astrocytes. The morphology of mesencephalic and striatal non-neuronal cultures is not very different (Figs 3*a* and *b*): the cells are not equally stained with the antibody, a fact that demonstrates some heterogeneity in the level of expression of the glial filament. The weak fluorescence of some cells cannot be attributed to cross-reactions with vimentin. This was checked by the absence of GFAP labelling of several virally transformed cell lines known to synthesize high amounts of vimentin[12] as well as by immunoblotting experiments (not shown). We have shown that 8-day old mesencephalic primary cultures contain a large proportion of vimentin-positive cells which cannot be labelled with GFAP antisera in double-labelling experiments nor with anti-fibronectin or anti-galacto cerebrosides antibodies[13]. Although we do not exclude the presence of other cell types such as immature oligodendrocytes, microglia or epithelial cells we agree with several authors[14,15] that the non-neuronal monolayers are mainly composed of astroblasts at various maturation stages and astrocytes.

Glial cells, peripheral and central, play important roles in promoting neuronal survival[16,17], neurite outgrowth[18,19], differentiation[20,21] and neurotransmitter choice[22,23]. Our study demonstrates that glial cells from two different embryonic brain areas have distinct and specific morphogenetic effects on the polarity and arborization of mesencephalic ascending DA neurones.

The morphological differences between DA cells plated on mesencephalic or striatal glial substratum could reflect different

Table 1 Morphology of dopaminergic neurones

	Arborization of dopaminergic neurones in: Mesencephalic glial monolayer		Striatal glial monolayer	
Days *in vitro*	Poorly branched	Highly branched	Poorly branched	Highly branched
2	458 (40%)	705 (60%)	1,103 (100%)	—
3	340 (36%)	1,008 (74%)	1,790 (100%)	—
10	210 (46%)	251 (54%)	327 (34%)	548 (66%)

Number of dopaminergic neurones exhibiting different morphologies when grown on the two different types of glial cell monolayers. This experiment has been repeated three times and about the same percentages of the two morphologies have been found in all experiments at two concentrations of freshly dissociated mesencephalic cells (5×10^5 and 10^6).

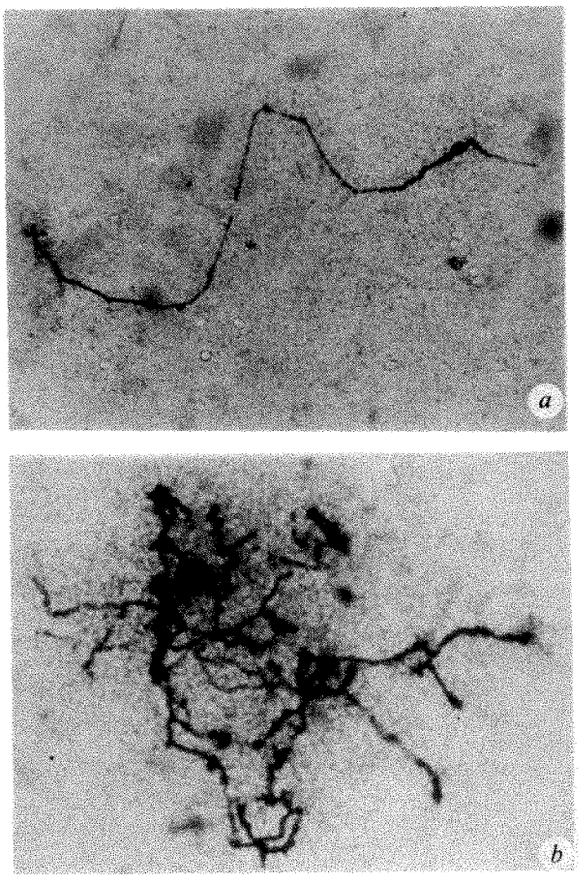

Fig. 2 Higher magnification of two neurones presented in Fig. 1. *a*, Dopaminergic neurones after 2 days *in vitro* on a monolayer of striatal glial cells (×300). *b*, Dopaminergic neurone after 2 days *in vitro* on a monolayer of mesencephalic glial cells (×300).

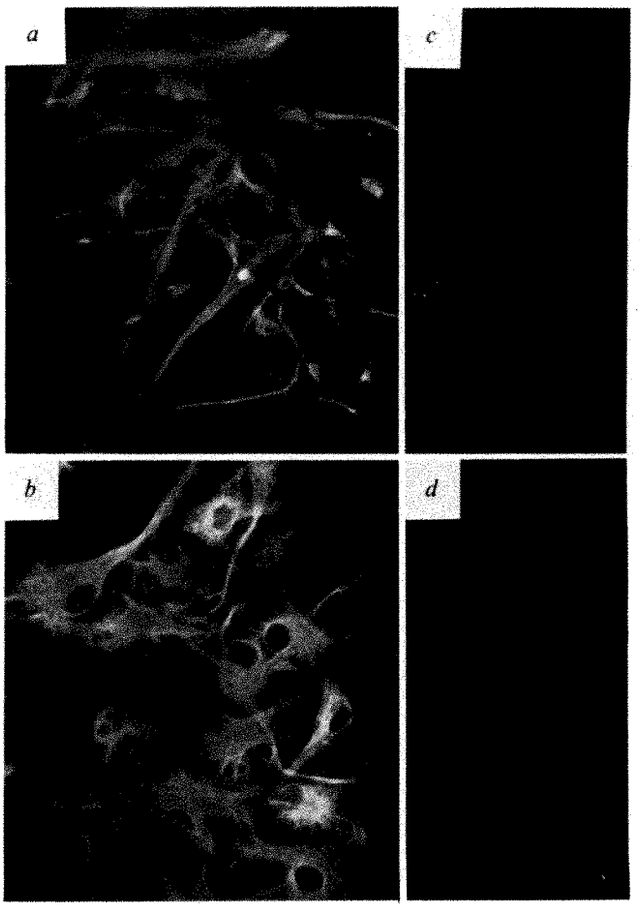

Fig. 3 Mesencephalic (*a*, *c*) and striatal (*b*, *d*) non-neuronal monolayers were prepared as described in Fig. 1. After 3 weeks in culture they were rinsed with PBS and permeabilized with a mixture of 3.7% formaldehyde and 1% methanol (Merck) for 1 h at room temperature. After several washes with PBS the cells were incubated 1 h at 37 °C with (*a*, *b*) or without (*b*, *d*) an antibody against glial fibrillary acidic protein (GFAP), raised in the rabbit. The second incubation was performed at 37 °C for 30 min with a solution of fluorescein-conjugated goat anti-rabbit immunoglobulins (1:50, Nordic). All incubations were in PBS containing 10% fetal calf serum. The cultures were mounted in PBS, glycerol (1:1) before examination under a Leitz HM-Lux microscope using a HBO 50-W mercury lamp. Magnification (×250).

developmental stages achieved by the neurones. This would mean that mesencephalic glial cells synthesize molecules that stimulate DA neurone development. Alternatively, the different morphologies of DA cells on both glial monolayers could arise by the specific selection by these monolayers of subpopulations of DA neurones. This seems not to be the case: the same number of DA cells is observed after 2 days *in vitro* on both substrata and since neurones growing a 'poorly branched' neurite can slowly develop a 'highly branched' arborization when mesencephalic glial cells have multiplied on the striatal monolayer. A third more interesting explanation comes from the observation that the morphological pattern obtained *in vitro* strikingly coincides with the geometry of the mesostriatal DA neurones. Indeed, during development, DA nigral neurones send their axons rostrally toward the striatum whereas the dendritic arborizations develop caudally in the nigral pars reticulata. It could be that on striatal as well as on a subpopulation of mesencephalic glia (40%), the unique neurite would represent an axon while on another subpopulation of mesencephalic non-neuronal cells (60%) DA neurones would be able to extend dendritic branches, with or without axon. Hemmendinger *et al.*[24] have already suggested that the formation of 'axon-like' processes depends on the presence of striatal or cortical target cells, whereas areas of extensive 'dendritic-like' arborizations are seen when DA neurones are in aggregates of mesencephalic cells only.

Since both neuronal morphologies can coexist in the same culture, either on mesencephalic glial cells or on striatal glial cells after 10 days when mesencephalic glia has been able to develop, diffusible molecules acting at long distances cannot be responsible for the observed phenomenon; close interactions between the neurite and its glial substratum are necessary.

In an earlier study we showed that striatal target cells are able to regulate *in vitro* the growth of DA neurones. In fact, DA processes transiently stop on these striatal target cells, while they ignore non-target mesencephalic or cerebellar cells[8]. It is, therefore, possible that direct contact is involved in stimulation and direction of axonal growth by striatal glial cells and recognition by axonal terminals of striatal target neurones. On the other hand the development of dendritic arborization could depend strictly on the signals provided by local mesencephalic glia.

We would like to thank M.-C. Daguet and A. Herbet for their critical and stimulating help. S.D.-D. was a recipient of a long-term EMBO fellowship. This work was supported by a grant from MRI no. 82 E 0125.

A dynorphinergic pathway of Leu-enkephalin production in rat substantia nigra

Nadav Zamir, Miklós Palkovits, Eckard Weber*, Éva Mezey & Michael J. Brownstein

Laboratory of Cell Biology, National Institute of Mental Health, Bethesda, Maryland 20205, USA
* Nancy Pritzker Laboratory of Behavioral Neurochemistry, Department of Psychiatry and Behavioral Sciences, Stanford University School of Medicine, Stanford, California 943305, USA

The amino acid sequence of the opioid peptide Leu-enkephalin[1–3] is found within several larger peptides[4–8], which are generated from the precursors proenkephalin and prodynorphin. Proenkephalin contains four copies of the sequence of Met-enkephalin, a single copy of the sequence of Leu-enkephalin and one copy each of two extended Met-enkephalin sequences[9–11]. Proenkephalin contains three peptides—α-*neo*-endorphin, dynorphin A and dynorphin B[12]—the N-terminal sequences of which are identical to that of Leu-enkephalin. There is good evidence that the large amounts of Leu-enkephalin found in the adrenal medulla are generated from the precursor proenkephalin[2,4,13,14], but as yet prodynorphin has not been shown to be processed to yield Leu-enkephalin. We show here that the relatively high levels of Leu-enkephalin found in the rat substantia nigra are supplied by striatonigral axons and generated from the precursor prodynorphin.

During our studies of the regional distributions of prodynorphin-related peptides, we observed that the concentrations of α- and β-*neo*-endorphin were considerably higher than the concentrations of dynorphin A (plus dynorphin A(1–8)) or dynorphin B[15,16]. This was especially striking in the substantia nigra and suggested to us that dynorphins A and/or B might be converted into smaller peptide species, including Leu-enkephalin. The fact that the level of Leu-enkephalin in the substantia nigra is more than twice as high as the level of Met-enkephalin-Arg-Gly-Leu, a peptide derived exclusively from proenkephalin (Table 1), also suggested that the Leu-enkephalin in this structure may not be derived exclusively from the proenkephalin precursor. Leu-enkephalin and Met-enkephalin-Arg-Gly-Leu are present in equimolar amounts in proenkephalin, and one may therefore expect their concentrations to be similar.

To determine the source of the Leu-enkephalin in the substantia nigra, we made unilateral knife cuts just rostral to the mesencephalon that transected descending fibres from the forebrain (Fig. 1, cut 2). These cuts resulted in a marked depletion of nigral α-*neo*-endorphin, dynorphin B and Leu-enkephalin, but did not affect levels of Met-enkephalin-Arg-Gly-Leu (Table 1). Thus, Met-enkephalin-Arg-Gly-Leu is probably not contained in descending inputs to substantia nigra. The dynorphin-related peptides and leu-enkephalin, on the other hand, must be in axons of neurones rostral to the substantia nigra.

In a second set of animals we made knife cuts that separate the globus pallidus from the caudate-putamen (Fig. 1, cut 1). These knife cuts also caused a substantial decrease in α-*neo*-endorphin, dynorphin B and Leu-enkephalin in the ipsilateral substantia nigra without altering the level of Met-enkephalin-Arg-Gly-Leu (Table 1). The same cuts resulted in decreases in

Table 1 Effects of various lesions on peptides in brain regions

Peptide	Treatment		Substantia nigra	Globus pallidus	Caudate

Brain areas investigated were substantia nigra, globus pallidus and caudate nucleus. Values are expressed as fmol peptide per mg protein. Data are means ±s.e.m. Lesioned side is compared with intact side by paired *t*-test: * $P < 0.001$, † $P < 0.01$, ‡ $P < 0.05$. When a percentage change is indicated the lesioned side and control sides differed significantly. Numbers in parentheses indicate the number of separate animals studied. GP, globus pallidus; Deaf., deafferentation.

Methods: Male Sprague–Dawley rats (200–250 g) were killed by decapitation (10 days after operation) and their brains removed. Tissue samples were microdissected from frozen 300-μm sections of the brains[22] after inspection of the lesions. Individual tissue samples were taken from the lesioned and control sides of the same section. Tissue samples were placed in Eppendorf tubes containing 200 μl of 0.1 M HCl and homogenized by sonication. 20-μl aliquots of the homogenates were taken for protein determination[23]. The homogenates were centrifuged at 2,000*g* for 10 min at 4 °C, and the supernatants were transferred to 12 × 75 mm polysterene tubes and evaporated to dryness in a vacuum centrifuge. The radioimmunoassay (RIA) procedure was that described in ref. 17 with some modifications. Samples were rehydrated in phosphate-buffered saline (*p*H 7.6). Antisera were used at final dilutions of 1:60,000 for α-*neo*-endorphin, and Leu-enkephalin, 1:100,000 for dynorphin B and 1:75,000 for Met-enkephalin-Arg-Gly-Leu, which resulted in 30–45% noncompetitive binding of the trace. Each sample was incubated in a 500-μl volume containing 300 μl of sample in assay buffer, 100 μl of ^{125}I-labelled opioid peptide (~6,000 c.p.m.). The tubes were then incubated at 4 °C for 16–24 h. In RIAs for α-*neo*-endorphin and dynorphin B, separation of bound from free peptide was effected by addition of 1 ml of dextran-coated charcoal. A double-antibody RIA for Leu-enkephalin and Met-enkephalin-Arg-Gly-Leu was performed as described here. Normal rabbit serum (NRS) was also added to the first antibody solution to give a total NRS concentration of 1%. 100 μl of this solution were added to all except 'nonspecific binding' tubes which received 100 μl of 1% NRS in assay buffer. Reagents were mixed and the tubes incubated for 16–24 h. 100 μl of goat anti-rabbit γ-globulin diluted with assay buffer to a concentration sufficient for maximal precipitation were added to all tubes. Reagent was mixed and the tubes were incubated for 16–24 h. After incubation with the second antibody, all tubes were centrifuged for 20 min at 2,000*g* at 4 °C. The supernatant was aspirated and pellets were counted in a γ-counter. The RIA sensitivities were less than 4 pg per tube. The specificities of the antisera for dynorphin B[24], α-*neo*-endorphin[25], Leu-enkephalin[25] and Met-enkephalin-Arg-Gly-Leu[26] have been described elsewhere. The α-*neo*-endorphin antiserum does not recognize the enkephalins and dynorphins at 1 μM concentration. The dynorphin B antiserum does not cross-react with the enkephalins, dynorphin A, dynorphin A(1–8) or *neo*-endorphins at 1 μM concentration. The Leu-enkephalin antiserum cross-reacts with Met-enkephalin to 0.35% and shows <0.01% cross-reactivity with dynorphins or *neo*-endorphins at 1 μM concentration. The Met-enkephalin-Arg-Gly-Leu antiserum cross-reacts <0.005% with Met-enkephalin, Met-enkephalin-Arg, Met-enkephalin-Arg-Arg, Met-enkephalin-Arg-Phe, BAM 12P, dynorphin A(1–8), α-*neo*-endorphin and human β-endorphin at 1 μM concentration.

α-*neo*-endorphin, Leu-enkephalin and Met-enkephalin-Arg-Gly-Leu in the globus pallidus (Table 1). This finding confirms an earlier observation of the (pro)enkephalinergic striatopallidal pathway[17] and suggests that there are also dynorphinergic striatonigral and striato (or cortico)-pallidal pathways.

Dynorphin-containing cell bodies have been reported in the caudate[18]. Indeed, Vincent *et al.* and Palkovits *et al.* have described a striatonigral dynorphin system[19,20]. We sought to visualize such neurones after globus pallidus isolation (cut 2), reasoning that a dynorphin build-up in axons and perikarya (see Table 1) might facilitate immunocytochemical staining. In these brains we demonstrate dynorphin B immunoreactivity building up in axons on the proximal (caudate) side of the cut (Fig. 2*a*) and a dense network of stained nerve fibres and numerous cell bodies in the head of the caudate nucleus at some distance from the lesion (Fig. 2*b–d*). No cell bodies and very few immunoreactive fibres were observed on the intact side of the brain. There was a significant decrease in immunostaining in the substantia nigra on the side of the lesion (data not shown).

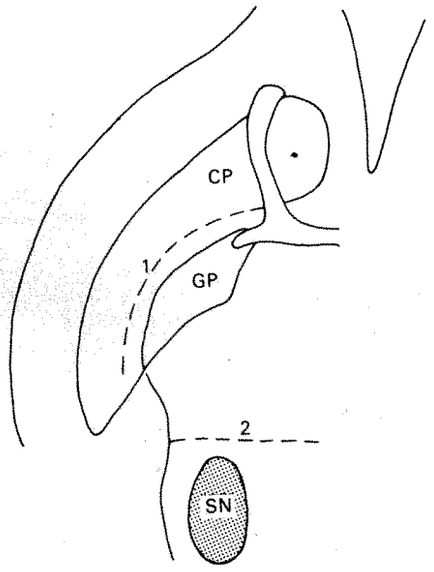

Fig. 1 Schematic representation of a horizontal section of the rat brain. CP, caudoputamen; GP, globus pallidus; SN, substantia nigra. 1, Unilateral knife cut isolating the caudate-putamen from globus pallidus. A Halasz knife[27] with a 2-mm radius and 3-mm height (the distance from the sleeve to the knife tip) was used to make this cut. The animal's head was fixed in a Kopf stereotaxic device (5°, nose down), and a rectangular flap of bone was removed from the skull. With the knife facing forward, the knife tip was placed 0.5 mm rostral to the bregma (~8.5 mm rostral to the interauricular line) and 2.5 mm lateral to the midline. The tip of the knife was lowered 7 mm beneath the surface of the dura and rotated 90° laterally. The knife was then moved caudally 2.5 mm, rostrally 2.5 mm and rotated medially 90° so that it was in its starting position in the brain. Finally, the knife was moved medially 2 mm, laterally 2 mm and withdrawn from the brain. 2, Unilateral mesencephalic cut transecting descending axons from caudate-putamen. This lesion was made with a 3-mm knife. The animal's head was fixed in a Kopf stereotaxic device (5°, nose down). The medial tip of the knife was placed 1 mm lateral to the midline 4.2 mm rostral to the interauricular line, and inserted ventrally until it touched the base of the brain. The animals were allowed to recover for 10 days, then they were decapitated and their brains were removed. Placement of all lesions was verified histologically.

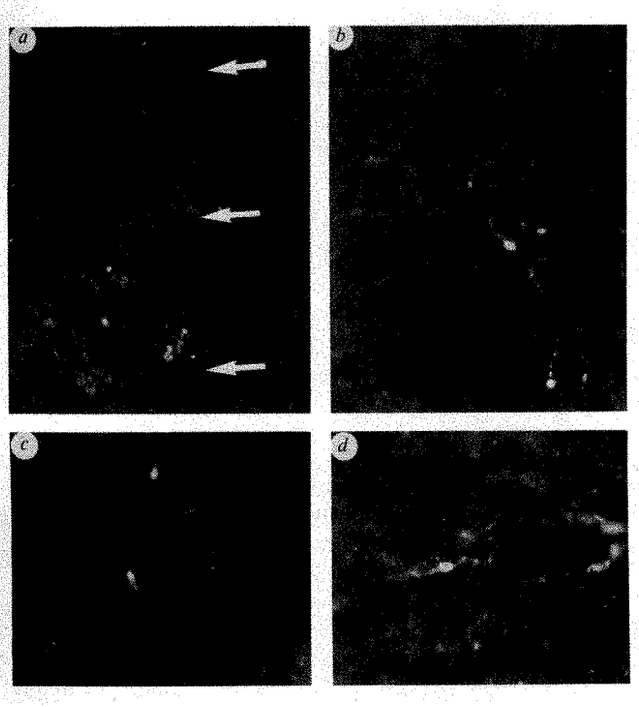

Fig. 2 *a*, Build-up of dynorphin B immunoreactivity in axons in the caudate nucleus proximal to a knife cut separating the globus pallidus from the striatum (arrow heads). ×75. *b–d*, Dynorphin B immunoreactive cell bodies in the head of the caudate nucleus. ×350.

Methods: Visualization of the dynorphin B immunoreactivity in brain tissue was carried out using the indirect fluorescent immunocytochemical technique[28]. The animals received an intraventricular injection of colchicine 24 h before they were anaesthetized with chloral hydrate and perfused with 4% phosphate-buffered paraformaldehyde solution. After a 90-min post-fixation the brains were washed in 0.1 M phosphate buffer overnight and then frozen on a liquid CO_2 stage. Cornal sections (10 μm thick) were cut in a microtome cryostat and mounted on gelatin-coated slides. The primary antibody, at a final dilution of 1:600, was incubated with the sections overnight at 4 °C. The sections were then incubated with rhodamine labelled secondary antibody (1:10) for 30 min at 37 °C. The slides were mounted in phosphate-buffered saline/glycerol and examined with a Zeiss microscope with epifluorescent illumination. There was no staining when the antibody was preabsorbed with an excess of dynorphin B.

Our data show that dynorphin-producing cells in the head of the caudate send fibres to the globus pallidus and substantia nigra. We cannot rule out the possibility that proenkephalin and prodynorphin coexist in the pallidal fibre population, but in the substantia nigra this does not seem to be the case, otherwise Met-enkephalin-Arg-Gly-Leu levels would decrease after striatonigral lesions, as do levels of *α-neo*-endorphin and dynorphin B. The most parsimonious explanation for the parallel decreases in *α-neo*-endorphin, dynorphin B and Leu-enkephalin is that in the striatonigral pathway Leu-enkephalin is made by dynorphinergic neurones.

Prodynorphin-derived peptides are potent κ-opiate receptor agonists[21] while Leu-enkephalin is a δ-opiate receptor agonist[21]. Thus, the same precursor (prodynorphin) may yield ligands for different opiate receptor subtypes that can exert different actions. The fact that Leu-enkephalin is derived from two separate precursors in brain may explain, in part, the different Leu-: Met-enkephalin ratios found in various brain regions.

Dual role for *Dictyostelium* contact site B in phagocytosis and developmental size regulation

C. M. Chadwick, J. E. Ellison & D. R. Garrod

CRC Medical Oncology Unit, Centre Block, CF99,
Southampton General Hospital,
Southampton, Hants SO9 4XY, UK

Three cohesion molecules have been discovered in the slime mould *Dictyostelium discoideum*[1-4]. Two of these molecules are involved in morphogenesis at the aggregation stage of the life cycle and thereafter, and may also provide an essential trigger for late gene expression[5]. The third glycoprotein 126 (gp126) or contact site B, is present on axenically grown vegetative amoebae and persists to the aggregation stage where it is involved in the side-to-side cohesion of cells in aggregation streams[1,4]. It is puzzling that vegetative amoebae should possess a cohesion molecule because their solitary habit does not necessitate cohesion. However, they do need to adhere to the substratum and adhesion of bacteria to the cells is a prerequisite for phagocytosis. Vogel *et al.*[6] have proposed that the same receptor is involved in phagocytosis and cohesion. It has also been suggested that contact site B-mediated cohesion is a trigger for development[7]. Using a specific antibody against gp126, we now show that contact site B is a phagocytosis receptor. Furthermore, contact site B is involved in regulating the size of aggregates formed during morphogenesis; it also seems to be involved in cell–substratum adhesion but is not a developmental trigger.

A rabbit antibody (designated CMC13) was raised against gp126 purified to homogeneity by SDS-polyacrylamide gel electrophoresis. gp126 was the only cell surface protein to be immunoprecipitated by this antibody from vegetative cells of strain Ax2 (Fig. 1*a*). (Previously, gp126 was termed p126, but it has been shown to be glycosylated by periodic acid–dansyl hydrazine staining[8].)

The first question investigated using this antibody was whether gp126 is a phagocytosis receptor. A phagocytosis assay was carried out essentially according to Glynn[9] using ^{14}C-lysine-labelled *Escherichia coli* strain B/r. Univalent Fab′ fragments were prepared from both CMC13 and a control antibody, designated N. CMC13 Fab′ completely inhibits cell cohesion at a concentration of 0.7 mg ml^{-1}. Fab′ N provides a suitable control because it binds to the cell surface but does not block cohesion[4]. In the phagocytosis assay (Fig. 2) CMC13 blocked phagocytosis at 0.1 mg ml^{-1} whereas Fab′N had no effect on phagocytosis at eight times this concentration. We conclude that gp126 is the phagocytosis receptor as well as being the vegetative cohesion molecule. This conclusion offers an explanation for the anomaly that vegetative axenic *D. discoideum* cells are cohesive[10], whereas vegetative cells grown on bacteria are non-cohesive (ref. 11 and our unpublished observations). Thus, cells involved in phagocytosis could be depleted of cell surface receptor molecules because of receptor internalization whereas axenic cells would have a full complement of receptor molecules on their surfaces. To test this, we immunoprecipitated extracts of axenically grown Ax2 cells, bacterially grown Ax2 cells and NC-4 (wild type) cells. Figure 1*b* shows that gp126 is dramatically reduced in bacterially grown cells. This confirms the view that the cohesion receptor and the bacterial receptor are the same.

To determine whether gp126 is also involved in cell–substratum adhesion log phase axenic cells were suspended at 2×10^4 ml^{-1} in Bonner's solution containing 1 mg ml^{-1} of inhibitory Fab′. They were then allowed to settle onto a coverslip 30 min in the presence of Fab′, after which time the slide inverted and the percentage of cells remaining attached after further 30 min determined. Controls used Fab′ N and Bonner solution alone. The percentage of cells remaining attached the various treatments was: Bonner's solution, 94%; Fab′ CMC 13 (1 mg ml^{-1}), 13%; Fab′ N (1 mg ml^{-1}), 95%. Therefore inhibitory Fab′ greatly reduces adhesion of cells to a substratum.

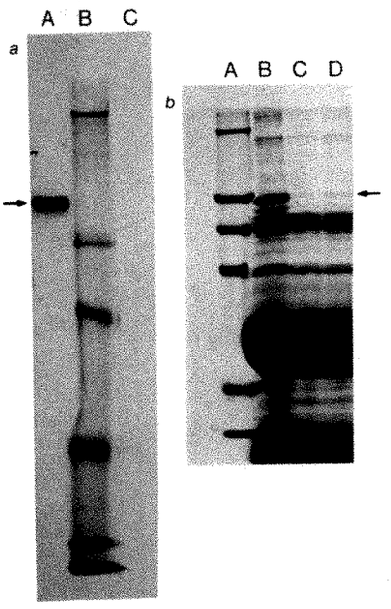

Fig. 1 *a*, Autoradiograph showing gp126 immunoprecipitate by CMC 13 IgG. Vegetative Ax2 cells were radioiodinated and detergent extract of the cells was immunoprecipitated with 150 μ CMC 13 IgG, using methods described elsewhere[4]. Lane A, ^{125} gp126 immunoprecipitated by CMC 13; B, ^{14}C-molecular weig (MW) markers (200,000, 92,000, 69,000, 46,000 and 30,000); pre-injection IgG. The same polypeptide (gp126) is the on Coomassie blue-stained band in immunoprecipitates of whole cel *b*, gp126 depleted in cells grown on *E. coli* B/r. Detergent extrac of 5×10^7 cells were immunoprecipitated by the anti-vegetati cell antiserum CMC 7 (see ref. 4). Lane A, MW markers (200,00 130,000, 97,400, 66,000, 45,000 and 29,000); B, axenic Ax2 cel C, Ax2 cells grown on *E. coli* B/r; D, NC4 cells grown on *E. c* B/r. The arrow denotes gp126.

Anti-gp126 Fab′ has allowed us to test whether contact B is a trigger for development[7]. Cells incubated in suspen in the presence of inhibitory Fab′ (1 mg ml^{-1}) became aggr tion-competent in 7–8 h. They did not cohere initially bu 7 h had developed the EDTA-resistant cohesion characte of the aggregation stage of the life cycle[1,2]. All cells posse stainable Fab′ on their surfaces after 7 h and the cell-free su natant was still able to inhibit the cohesion of vegetative Cells incubated on Millipore filters in the presence of inhib Fab′ developed synchronously to the fruiting body stage in as did control cultures; the only difference was that grexes fruiting bodies formed in the presence of inhibitory Fab′ much smaller than those in control cultures (Fig. 3). This d ence in morphology was similar to that shown by develc Ax2 cells grown in the absence and presence of glucose[12]. gp126 makes a significant contribution to the cohesivene developing cells and has a role in size regulation. Blocki gp126 with inhibitory Fab′ reduces cellular cohesiveness thereby reduces aggregate, and hence fruiting body, Development in the presence of inhibitory IgG was en normal, presumably because capping results in its removal the cell surface. Because cells can develop in conditions in

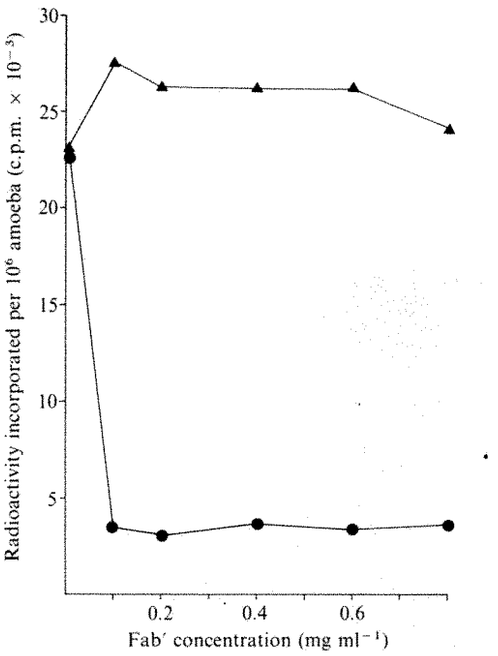

Fig. 2 Phagocytosis of ^{14}C-labelled *E. coli* B/r. ▲, Fab′ N; ●, CMC 13 Fab′. *E. coli* B/r was labelled by growth overnight in 100 ml of a shaken (140 r.p.m., 35 °C) solution of 0.05% sodium citrate, 0.1% $(NH)_2SO_4$, 0.3% KH_2PO_4, 0.7% K_2HPO_4, 0.01% $MgSO_4 \cdot 7H_2O$, 0.27% glucose containing 0.25 μCi ml^{-1} L-[U-^{14}C]lysine (Amersham). Bacteria were washed in 17 mm Na/K phosphate buffer, and suspended in buffer at 2×10^9 ml^{-1}. Log phase axenic amoebae were washed in phosphate buffer and suspended in buffer at 2×10^6 cells ml^{-1}. Samples (0.5 ml) of amoebae were mixed with 1 ml phosphate buffer containing Fab′ at the appropriate concentration. The Fab′ was allowed to bind to the cells for 10 min, then 0.5 ml of *E. coli* was added and the resulting suspension shaken for 90 min at 140 r.p.m., 22 °C. Phagocytosis was stopped with 2 ml of 4% glutaraldehyde. After 5 min of fixation, 5×10^7 stationary phase Ax2 cells were added as a carrier. Cells were collected by bench centrifugation then washed twice in 17 mM Na/K phosphate buffer to remove unbound *E. coli*. The pellet of washed cells was dissolved in 2 ml of scintillant (750 ml Triton X-100, 1,500 ml toluene, 6 g 2,5-diphenyloxazole). The radioactivity was measured with a Packard Tri Carb 300 β-counter. The specific radioactivity of the *E. coli* suspension was 34,500 c.p.m. per 10^8 bacteria. As a maximum of 27,000 c.p.m. was incorporated into 10^6 amoebae (in the presence of Fab′ N), each amoeba bound an average of 78 bacteria in permissive conditions. Glynn[9] obtained a value of 80 bacteria per cell.

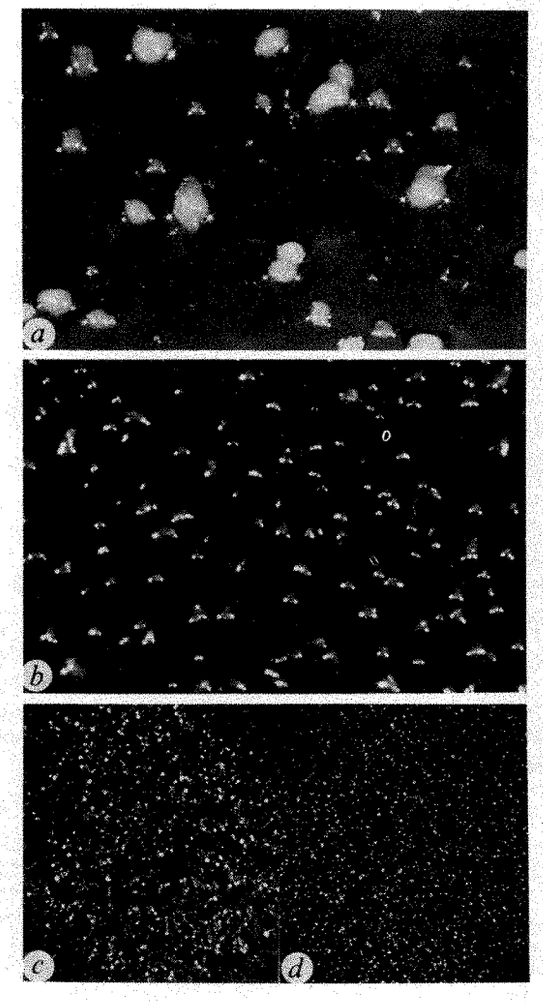

Fig. 3 Size regulation. *a*, Control grexes in Fab′ N (18 h). (×6.5.) *b*, Grexes in inhibitory Fab′ (18 h). (×6.5.) *c*, Control fruiting bodies in Fab′ N (24 h). (×1.2.) *d*, Fruiting bodies in inhibitory Fab′ (24 h). (×1.2.) Axenically grown cells were allowed to develop on Millipore filters according to the method of Sussman[13]. Inhibitory Fab′ (1.5 mg ml^{-1}) was added to the culture solution. The cells were allowed to develop for 24 h at 22 °C and were observed at intervals.

gp126-mediated cohesion is blocked, this molecule cannot be a developmental trigger.

Thus, the *Dictyostelium* cohesion molecule known as contact site B or gp126 has a dual role in phagocytosis and morphogenetic size regulation. We speculate that this is of evolutionary significance since the development of receptor-mediated phagocytosis could have provided the basis for cell–cell adhesion and hence the multicellularity displayed by higher organisms. It is possible that gp126 is related to the nonspecific receptor postulated by Vogel *et al.*[6], because it also seems to be involved in cell adhesion to glass.

Endothelial cells of the arterial vascular system and the heart contain straight actin filament bundles, of which there are few, if any, in the venous endothelium[1–4]. Since stress fibre-containing endothelial cells within the vascular system tend to be located at sites exposed to particularly high shear stress of blood flow, we have investigated, in an experimental rheological system (Fig. 1), the response of the endothelial actin filament skeleton to controlled levels of fluid shear stress. Here we report that endothelial stress fibres can be induced by a 3-h exposure of confluent monolayer cultures of human vascular endothelium to a fluid shear stress of 2 dynes cm^{-2}, approximately the stress occurring in human arteries *in vivo*. Fourfold lower levels of shear stress that normally occur only in veins, had no significant effect on the endothelial actin filament system. The formation of endothelial stress fibres in response to critical levels of fluid shear stress is probably a functionally important mechanism that protects the endothelium from hydrodynamic injury and detachment.

Endothelial cells were collected from human umbilical vein[5] and grown on glass coverslips previously coated with a layer of extracellular matrix[6]. This coating (achieved by precultivation of the coverslips with bovine corneal endothelial cells) was important in that it allowed the formation of confluent human endothelial monolayer cultures that were firmly attached to the substrate (Fig. 2). Cells grown on glass were generally less firmly attached to the surface as revealed by occasional detachment of individual cells and even large groups of cells during exposure to fluid shear stress. Fluorescent staining of the confluent cultures with rhodamine-labelled phalloidin (a specific probe for polymerized actin[7]) and with antibodies to calf thymus myosin[2] and chicken gizzard and pectoral muscle α-actinin[8] showed a rather uniform pattern of stress fibres (Fig. 3). The stress fibres displayed the typical continuous staining for actin and an interrupted pattern for myosin and α-actinin similar to the descriptions of stress fibres found in cultured aortic endothelium[1,9] and other tissue culture cells (for a recent review, see refs 10, 11). Stress fibre staining was most prominent in the peripheral cytoplasm close to the margin of the polygonally-shaped cells. We often observed intensely stained focal areas from which numerous stress fibres were seen to radiate in various directions. Outside the marginal zone intensely stained stress fibres were rather infrequent. Most of the relatively few stress fibres projecting over the central parts of the cells appeared to be rather thin and were only faintly stained.

Controlled levels of shear stress were then applied by using a transparent rotating cone placed with its tip on the centre of the coverslips (Fig. 1). Rotation of the cone caused the culture medium to flow between the cone and the surface of the coverslip. In this study a lamina flow was chosen, producing a shear stress of 2 dynes cm^{-2}, which is about the minimum level in human arteries for basal conditions (2–20 dynes cm^{-2}, locally up to 100 dynes cm^{-2})[12]. No changes in cellular shape or position occurred during exposure to shear stress, as judged by phase contrast microscopy and TV recording of the endothelium throughout the exposure period (1, 2, 3 and 4 h). Temperature and *p*H of the medium were kept constant during the experiments.

After a 3-h exposure to shear stress, the quantity and staining intensity of stress fibres had dramatically increased (Fig. 3). No preferential alignment or direction of the newly formed stress fibres was seen. The exact time course of induction of stress fibres has so far not been determined. At present we can only state that after a 1-h exposure to shear stress there was no increase in the amount of stress fibres, but a slight increase was observed after 2 h. After 4 h the quantity and density of stress fibres were about the same as after 3 h of exposure to shear stress. Thus most stress fibres seemed to have developed during the second and third hour of shear stress treatment. When the shear stress was reduced to fourfold lower levels (0.5 dynes cm^{-2}), a level normally found only in the venous system, no significant increase in the quantity of stress fibres was seen after 3 h of exposure.

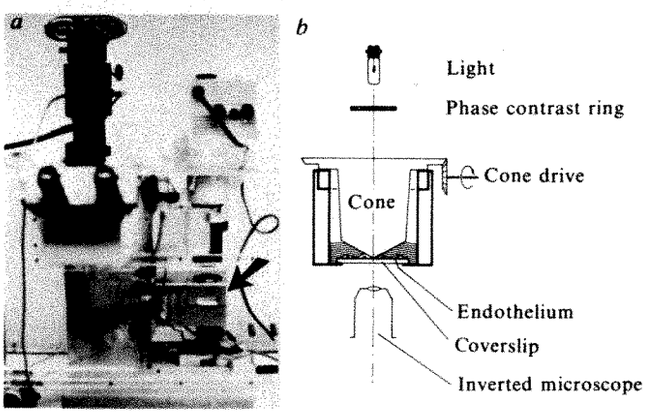

Fig. 1 *a*, Rheoscope used in this study. The construction is based on a cone and plate mechanism originally developed for microrheological studies of blood cell aggregations[20]. An arrow indicates the rheoscope chamber, which is shown in *b* in simplified cross-sectional form (not to scale). A transparent polycarbonate cone having an angle of 2.5° is fitted into a Plexiglas holder and connected to a speed-controlled motor with variable rotational velocities. The cone is placed with its tip on the surface of the coverslip under microscopic control. The direction and magnitude of shear stress were determined precisely both by direct measurements and from theory (ref. 21 and our unpublished data).

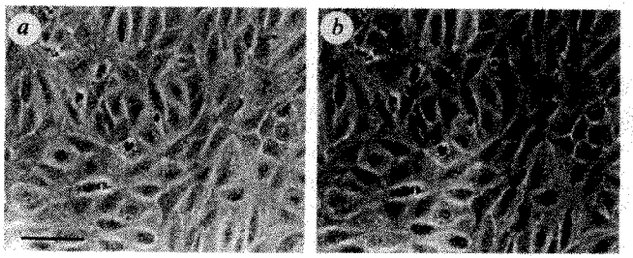

Fig. 2 *a*, *b*, Phase contrast micrographs of confluent monolayer cultures of human vascular endothelial cells collected from the umbilical vein[5], cultured in medium TC 199 containing 20% pooled human serum and 1 mg ml^{-1} endothelial growth supplement extracted from bovine brain[22]. Cells were seeded on coverslips previously coated with an extracellular matrix layer consisting of bovine corneal endothelium[6], and were grown for 8–10 days. The same area of the monolayer was monitored throughout the exposure to fluid shear stress (2 dynes cm^{-2}). *a*, Before shear stress exposure; *b*, after 3 h of exposure. No changes in cellular shape or position have occurred. Scale bar, 100 μm.

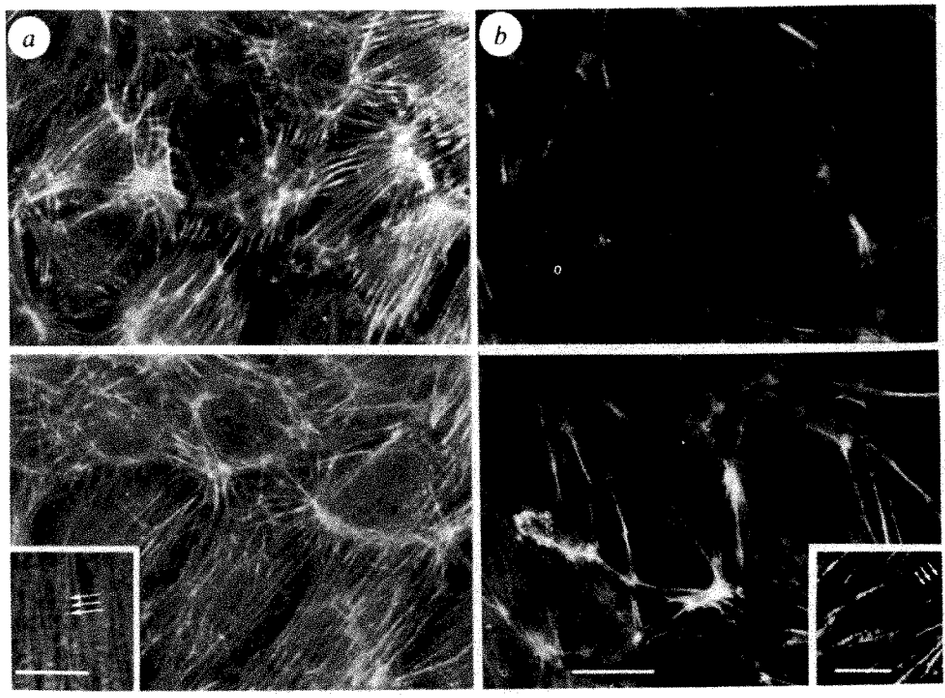

Fig. 3 *a*, Pattern of actin filament bundles (stress fibres) in human endothelial monolayer cultures (two examples are shown) after 3 h of exposure to low arterial levels of fluid shear stress (2 dynes m^{-2}). *b*, Corresponding controls. Scale bar, 20 μm. Only the central parts of the monolayers (area of ~1 cm^2) were examined, because endothelial cells located close to the margin of the coverslips were still in a subconfluent state and thus contained varying amounts of stress fibres. Each shear stress experiment was followed by a control experiment in which corresponding cultures were placed in the rheoscope chamber for the same length of time as for exposure to shear stress, but without rotation of the cone. Stress fibres were visualized by fluorescent staining with 1.4 μg ml^{-1} tetramethylrhodaminyl- which was applied to the monolayers after 5 min of fixation with 2% paraformaldehyde in phosphate-buffered saline and 3 min of permeabilization with 80% acetone (all steps were done at room temperature). The insets show stress fibres at higher magnification (scale bars, 10 μm) stained with antibodies to calf thymus myosin (inset in *a*) and chicken gizzard α-actinin (inset in *b*) using the indirect immunofluorescence technique described elsewhere[2].

Although no attempts were made to determine the threshold value of shear stress that induces stress fibre formation in this *in vitro* system, the experiments reported here clearly show that at a critical level of fluid shear force (which seems to be much lower *in vitro* than *in situ*) endothelial cells will respond by forming stress fibres. These stress fibres probably protect the cells against the shear stress of fluid flow. In view of the observation that isolated stress fibres can contract in appropriate conditions[13,14], it seems reasonable to assume that endothelial stress fibres may apply tension to resist the shear forces acting on the cells, thus allowing the cells to maintain their flattened phenotype and to remain firmly attached to the substratum. To a certain degree, stress fibre formation may prevent hydrodynamic damage to the endothelium and thus protect the vascular wall from certain pathological stimuli such as those thought to be involved in the initiation of arteriosclerosis[15].

The shear-induced stress fibres were more or less randomly distributed with respect to the direction of fluid flow. This pattern apparently differs from the alignment of stress fibres in arterial endothelial cells *in situ*, which is characterized by orientation of the fibres parallel to the direction of blood flow[1–4,16]. However, as the arterial endothelium consists of elongated cells having their long axis oriented in the direction of blood flow (this kind of orientation is probably caused by long-term shear stress in one direction)[17], and in view of the fact that in elongated, cultured cells stress fibres are mainly aligned parallel to the cellular long axis[18], it seems likely that the uniform alignment of arterial endothelial stress fibres parallel to the blood flow depends on the particular orientation of arterial endothelial cells rather than on direct actions of fluid shear stress on the orientation of stress fibres. In the experimental conditions of the present study, the confluent polygonal endothelial cells did not change their shape during shear stress; this is probably the reason why the induced stress fibres did not display a uniform alignment in the direction of the fluid flow. Support for this view comes from regenerating arterial endothelial cells of the rabbit aorta: at the edges of the outgrowing endothelium, stress fibres were frequently found oriented diagonally or even perpendicularly to the blood flow but the fibres were always aligned parallel to the cellular long axis[3]. Similar observations were obtained with subconfluent and confluent cultures of endothelium exposed to long-term (1–2 days) shear stress. Reorientation of endothelial cells in the direction of the fluid flow was accompanied by re-alignment of the stress fibres which were always (before and after the shear treatment) oriented roughly parallel to the cellular long axis (ref. 19 and our unpublished observations). However, such changes in the alignment of stress fibres seem to be only secondary effects brought about by shear stress-induced reorientation of endothelial cells.

The present study provides the first evidence that in human vascular endothelium, fluid shear stress may act directly on the stress fibre system without affecting cellular shape and orientation. The factors mediating this response of the endothelial actin filament system remain to be determined.

Chondroitin sulphate proteoglycans are widespread connective tissue components[1–4] and chemical analysis of cartilage and other proteoglycans has demonstrated molecular speciation involving the degree and position of sulphation of the carbohydrate chains[5,6]. This may, in turn, affect the properties of the glycosaminoglycan (GAG), particularly with respect to self-association and interactions with other extracellular matrix components[6,7]. Interactions with specific molecules from different connective tissue types, such as the collagens[8,9] and their associated glycoproteins[10,11], could be favoured by particular charge organizations on the GAG molecule endowed by the sulphate groups. So far, it has not been possible to identify and map chondroitins of differing sulphation in tissues, but we have now raised three monoclonal antibodies which specifically recognize unsulphated, 4-sulphated and 6-sulphated chondroitin and dermatan sulphate. These provide novel opportunities to study the *in vivo* distribution of chondroitin sulphate proteoglycans. We demonstrate that chondroitin sulphates exhibit remarkable connective tissue specificity and furthermore provide evidence that some proteoglycans may predominantly carry only one type of chondroitin sulphate chain.

The characteristics, specificity and designation of each antibody are given in Table 1 and Fig. 1. Details of the methodology and protocols used are given elsewhere[12]. Rat tissue sections for indirect immunofluorescence staining with these antibodies required pretreatment with GAG-degrading enzymes to liberate the specific antigen as listed in Table 1. The omission of enzyme treatment in the staining schedule served as a control revealing nonspecific staining and was negative for each monoclonal antibody. Figure 1*c* shows that 3-B-3 antibody has minor activity against unsulphated chondroitin (C0-S) in addition to the major determinant, chondroitin 6-sulphate (C6-S). However, the comparative use of both the 1-B-5 and 3-B-3 antibodies allows the distribution of C0-S and C6-S to be easily determined.

In the rat we found that the distribution of C0-S was virtually restricted to cartilage (Fig. 2*a*) since the 1-B-5 antibody stained articular and hyaline cartilage brightly, but this antibody did not stain dermis or other connective tissues apart from a faint staining in the intima of rat aorta (Fig. 2*b*). However, chondroitin 4-sulphate (C4-S) and/or dematan sulphate (DS) was more widely distributed than unsulphated chondroitin. In addition to cartilage staining by the 9-A-2 antibody (Fig. 3*a*), fluorescence was widely distributed in loose connective tissue. The dermis, in particular, was well stained in a fibrillar pattern suggesting some association with dermal collagen fibres (Fig. 3*b*) as was the connective tissue supporting blood vessels, nerve fibres and striated muscle from a variety of locations (Fig. 3*c*). The media and adventitia of the aorta stained positively as did the kidney mesangium (Figs 3*d*, *e*). Epithelia and endothelial components of the skin (Fig. 3*b*), aorta (Fig. 3*d*) and kidney were themselves negative as were their supporting basement membrane zones (BMZ), including those of the glomerulus. The indications are that a BMZ population of C4-S or DS was not detectable. A further series of experiments was performed to establish whether some or all of the loose connective tissue staining was in fact chondroitin 4-sulphate (C4-S) or dermatan sulphate (DS). Accordingly, tissue sections were pretreated with

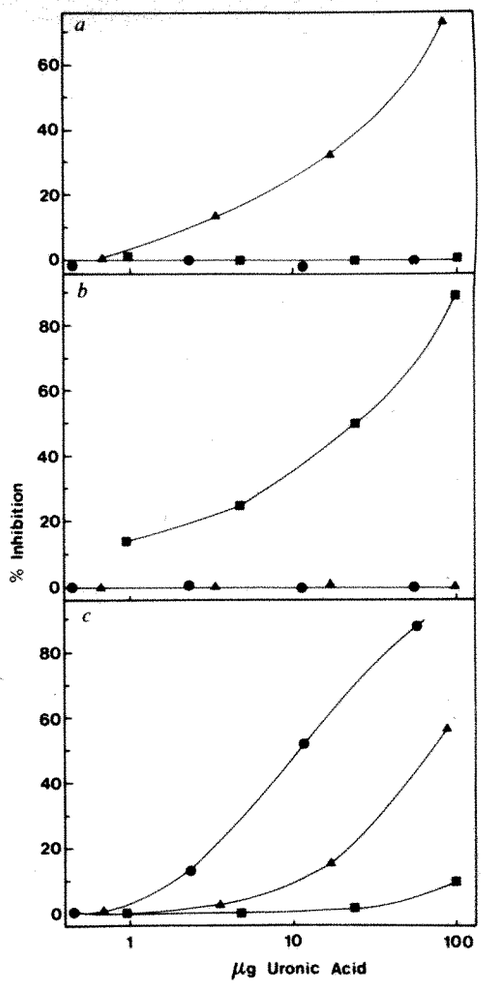

Fig. 1 Antibody characterization by inhibition of the binding of ^{125}I-labelled chondroitinase ABC-digested rat chondrosarcoma proteoglycan to monoclonal antibodies as a function of the concentration of chondroitin sulphate disaccharides. The disaccharides tested were 2-acetamido-2-deoxy-3-*O*-(β-D-gluco-4-enepyranosyluronic acid)-4-*O*-sulpho-D-galactose (■), the corresponding 6-sulphated disaccharide (●), and the nonsulphated disaccharide (▲). ^{125}I-antigen (about 1 ng of protein containing 3×10^4 c.p.m.) and chondroitin sulphate disaccharides in the amounts indicated were incubated with *a*, antibody 1-B-5 (1/400 dilution of ascites fluid), *b*, antibody 9-A-2 (1/100 dilution), or *c*, antibody 3-B-3 (1/400 dilution) in a total volume of 200 μl of buffer containing 0.5% deoxycholate, 0.1% Nonidet P-40, 0.1% bovine serum albumin, 0.15 M NaCl, 0.03% NaN_3, 0.01 M sodium phosphate, *p*H 8.0. After incubation at room temperature (22–25 °C) for 90 min the antibody-bound antigen was separated from the unbound using heat- and formalin-inactivated *Staphylococcus aureus* cells as described previously[30]. Per cent inhibition was calculated relative to the amount of ^{125}I-labelled antigen bound to the antibody in the absence of added chondroitin sulphate disaccharides. The conditions for use of the antibodies are shown in Table 1.

chondroitinase ACII in place of chondroitinase ABC. Under these conditions C4-S but not DS is digested[13]. We found that cartilage staining persisted (Fig. 3*f*) but the dermis of skin and other loose connective tissue was now weakly stained or unstained (Fig. 3*g*). We, therefore, deduce that the staining depicted in Figs 3*a* and *b* is largely derived from DS.

Chondroitin 6-sulphate (C6-S) distributions were revealed by the 3-B-3 antibody after chondroitinase ABC or testicular hyaluronidase pretreatment of tissue sections. In addition to cartilage staining (Fig. 4*a*), very heavy staining of the intima and media of the aorta was detected (Fig. 4*c*) as was a remarkable specificity for a number of BMZ in the rat including those of blood vessel endothelia, muscle, peripheral nerve fibres, the

© 1984 Macmillan Journals Ltd

dermal/epidermal junction, kidney tubules and the glomerulus (Figs 4*a–f*). Further tests were carried out by enzyme-linked immunosorbent assay and no cross-reactivity (not shown) between the antibody and other previously characterized BMZ components such as laminin[14] and type IV collagen[15] was detected. Antigen adsorption with rat liver heparan sulphate proteoglycan[16] did not block BMZ staining. In addition, the tissue-staining patterns seen with two antisera against heparan sulphate proteoglycan[17,18] were quite distinct from that with the 3-B-3 antibody (not shown). The presence of a BMZ population of C6-S proteoglycan has not previously been shown by immunohistochemical means, but chemical analysis of glomerular BMZ has indicated a minor amount of chondroitin sulphate in addition to the predominant GAG, heparan sulphate[19,20]. The presence of a chondroitin sulphate proteoglycan in the supernatants of vascular endothelial cell cultures has recently been reported and is consistent with our results[21]. The precise localization of C6-S within BMZ is currently under investigation by electron microscopy.

Although the antigens for monoclonal antibody production were in each case of cartilage origin, the epitopes recognized by the antibodies are common to other connective tissue locations and are revealed by chondroitinase ABC pretreatment. The possibility that masking of other potentially antigenic sites occurs through the interaction with other components cannot be discounted but seems unlikely in view of the specificity of staining patterns shown here. Moreover, our findings agree in principle with previous chemical analyses of whole tissues. For example, chondroitin chains with differing sulphation (C0-S, C4-S and C6-S) have been reported from cartilage[22], and we found that all three monoclonals stained both articular and hyaline cartilage intensely. Similarly, the predominant GAG types in aorta have been reported to be C6-S and DS[23], results entirely consistent with our immunofluorescence localizations. An advantage of our methods is, however, that we have shown that these two chondroitin subspecies do not share the same tissue locations (Figs 3, 4). While C6-S was present only in the intima and media, C4-S was prominent in the adventitia region and also the media but not the intima. This is just one example of the much higher resolution that can be achieved by immunohistochemical detection of glycosaminoglycans over previous methods. Some similarity in properties between cartilage and aorta proteoglycans have also been noted before[24,25]. In contrast to cartilage it seems that for other tissue locations chondroitin sulphate chains of only one major type are covalently bound to a specific protein core. Other reports have

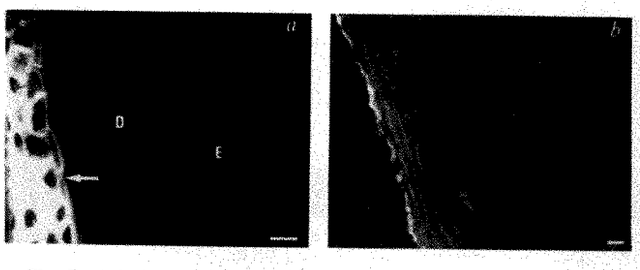

Fig. 2 1-B-5 antibody staining showing the distribution of unsulphated chondroitin in chondroitinase ABC treated (0.2 U ml^{-1} in 0.1 M Tris-acetate *p*H 7.3 containing 1 mg ml^{-1} bovine serum albumin) rat ear (*a*) and aorta (*b*) sections. Cartilage was heavily stained (arrow), but the epidermis (E) and dermis (D) with its associated muscle fibres, blood vessels and nerve fibres were unstained. The intima of the rat aorta was weakly positive with the 1-B-5 antibody. Scale bars, 15 μm. For this and all other staining, small pieces of freshly excised tissue from rats were snap-frozen in isopentane chilled in liquid nitrogen. Cryostat sections (6–8 μm) were briefly air-dried, fixed for 15 min in 3% formaldehyde, then washed repeatedly in Dulbecco's phosphate-buffered saline, including one 15-min wash supplemented with 0.1 M ammonium chloride. Antibody staining was for 30–45 min at 37 °C in a wet-box with several washes between applications.

suggested that chondroitin sulphates of different types may occur within a single chain[26]. One possibility for future consideration in this regard is that the striking tissue specificity of chondroitin sulphates shown here may reside in the disaccharides adjacent to the protein core of the proteoglycan, these remaining after enzyme treatment. Mixed forms of chondroitin sulphate, if present in more distal regions of the chondroitin chains would then be preferentially removed by the enzyme before antibody application. Recently, we have characterized an additional monoclonal antibody which specifically recognizes keratan sulphate and which could also be used for immunohistochemical analyses by techniques similar to those reported here[12].

This work has two important implications. First, the different forms of chondroitin recognized by the three monoclonal antibodies have distinct and often separable distributions. Our observations further indicate that the proteoglycans involved may predominantly carry only one type of chondroitin chain with respect to sulphation. If these deductions are correct it is possible that the core proteins of the chondroitin proteoglycans are distinct gene products expressed in a tissue or cell-specific manner with a concomitant specificity of chondroitin sulphate

Table 1 Conditions for use of the antibodies

Monoclonal antibody designation	Antigen	Antibody source for staining	Antibody class and working dilution	Second antibody and working dilution	Antibody specificity
1-B-5	Chondroitinase ABC digested rat chondrosarcoma proteoglycan	Ascites fluid	IgG1 1:50	Affinity purified goat anti-mouse IgG1-FITC or TRITC 0.05 mg ml^{-1}	Unsaturated uronic acid* residue linked to *N*-acetylgalactosamine
9-A-2	Chondroitinase ABC digested bovine articular cartilage proteoglycan	Ascites fluid	IgG1 1:50	Affinity purified goat anti-mouse IgG1-FITC or TRITC 0.05 mg ml^{-1}	Unsaturated uronic acid* residue linked to *N*-acetylgalactosamine 4-sulphate
3-B-3	Chondroitinase ABC digested rat chondrosarcoma proteoglycan	Ascites fluid	IgM 1:50	Affinity purified goat anti-mouse IgM-FITC or TRITC 0.1 mg ml^{-1}	Unsaturated* or saturated uronic acid residue linked to *N*-acetylgalactosamine 6-sulphate Some activity against unsulphated derivative

FITC, fluorescein isothiocyanate; TRITC, tetramethylrhodamine isothiocyanate.
*These represent the residues from chondroitinase ABC digestion of chondroitin, chondroitin 4-sulphate and chondroitin 6-sulphate respectively.

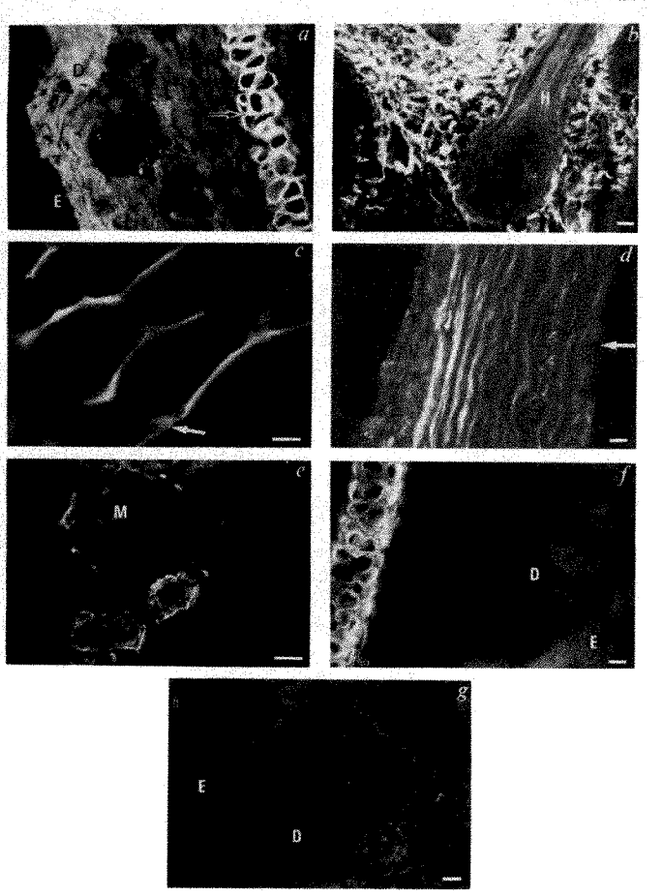

Fig. 3 9-A-2 antibody staining on rat tissue sections pretreated with chondroitinase ABC (*a–e*) to stain C4-S and DS, or chondroitinase AC II (*f*, *g*) to stain C4-S only[12]. *a*, Ear cartilage (arrow) and dermal connective tissue (D) were heavily stained, but the epidermis (E) was negative. Dorsal rat skin dermis (*b*) had a fibrillar staining pattern and the epithelia of the hair shaft (H) were unstained. *c*, Connective tissue surrounding striated muscle and blood vessels (arrow) were also positively stained with this antibody. *d*, Staining was seen through most of the cross-section of rat aorta but no staining of the endothelial basement membrane zone was visible (arrow). *e*, Connective tissue surrounding kidney blood vessels and Bowman's capsule were positively stained together with weak staining of the mesangium (M). The tubular and glomerular basement membrane zones were apparently unstained. *f*, *g*, Sections of rat ear and dorsal skin respectively after chondroitinase AC II pretreatment (compare *a* and *b*). Only cartilage staining persisted indicating the presence of C4-S. Dermal connective tissue staining was lost indicating that it contained DS. Scale bars, 15 μm.

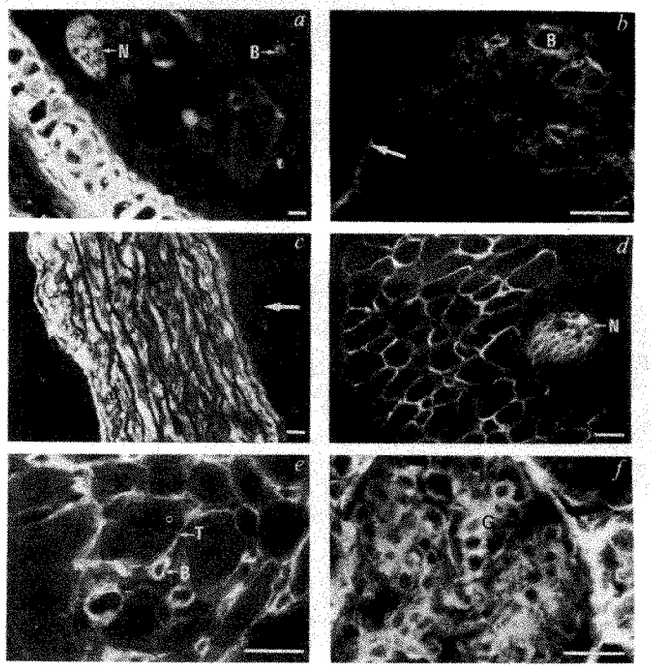

Fig. 4 Distribution of C6-S in chondroitinase ABC-treated rat tissue sections as revealed by the 3-B-3 antibody. In addition to ear cartilage (*a*), this antibody stained basement membrane zones of dermal nerve fibres (N) and blood vessels (B) (*a*, *b*), the dermo-epidermal junction (arrow) (*b*), intima and media of aorta but not adventitia (arrow) (*c*), basement membrane zones of striated muscle and associated nerve fibres (*d*) and those of kidney tubules (T) and glomerulus (G) (*e*, *f*). Scale bar, 15 μm.

chains. Our data therefore provide further evidence for the specificity of connective tissue types, seen previously in terms of both collagenous[15,27,28] and non-collagenous glycoproteins such as laminin[14] and chondronectin[29]. The specificity of sulphation of chondroitin sulphate proteoglycan in connective tissues may facilitate interactions with other matrix components.

We believe that these antibodies can be used to isolate and characterize the chondroitin sulphate proteoglycans and their protein cores from a variety of tissue sources. In particular, distinct protein cores can be isolated from mixed populations of proteoglycans; at present very little is known regarding the relationship between them and their interactions with other matrix components. Our preliminary findings also suggest that the antibodies have wide cross-species reactivity, as might be expected from the highly conserved nature of GAG chains. Antibodies such as these will therefore be valuable in the elucidation of the functions of chondroitin sulphate proteoglycans in human connective tissue synthesis and assembly as well as their roles in many pathological conditions.

We thank Dr J. F. Kearney (University of Alabama) for purified fluorochrome-conjugated antibodies and Ms L. Lewis for technical assistance. This work was supported by NIH grants HL 28195, AM 27308, AM 32474.

Is stepwise sarcomere shortening an artefact?

John D. Altringham*, Roberto Bottinelli† & Joan W. Lacktis‡

A report[1] in 1977 raised the intriguing possibility that sarcomere shortening in muscle may occur in a stepwise fashion, in which episodes of shortening are interrupted by periods of little or no movement. This was taken by its authors to imply the synchronous activity of cross-bridges over a large volume of tissue—behaviour which cannot easily be reconciled with commonly accepted views of muscle contraction[2–5]. Stepwise shortening has also been reported recently in relaxed muscle fibres on which length changes were externally imposed[4,6,7], and that system has allowed us to define more rigorously the circumstances in which stepwise shortening is observed. Here we report a high correlation between the frequency of 'steps' or 'pauses' and the translation velocity of the fibre past the measuring system, suggesting that stepwise shortening is not a physiological property of muscle but an instrumentation artefact.

To measure sarcomere length, we used two independent methods which have previously been used to study stepwise shortening: diffraction of laser light by the periodic arrangement of sarcomeres along the length of a muscle fibre[8], and an optical imaging technique using a phase-locked loop (PLL)[9]. Changes of sarcomere length were brought about in single frog muscle fibres (see Fig. 1 legend) by anchoring one end and stretching and releasing the other. The effects of different translation velocities were studied either (1) by releasing at a constant speed but observing at different points along the fibre (exploiting the gradient of velocity from the fixed to the moving end of a fibre), or (2) by varying the speed of the release and observing at a fixed point. In each case, natural markers on the fibres were used as points of reference. Both methods yield records showing the variation with time of sarcomere length at the point observed, from which the frequency of steps (evident in a variable proportion of experiments) could be calculated.

The results are summarized in Fig. 1 (laser diffraction) and Fig. 2 (optical imaging). In most experiments, the 'pauses' were inclined to the horizontal, giving the records a 'saw-tooth' appearance, but we have seen no justification for selecting only flat pauses in our analysis, as flat and inclined pauses often occurred on the same record. With each method, plots of frequency against the translation velocity of the point of the fibre observed fall on straight lines with correlation coefficients near unity. Extrapolation to zero shortening velocity predicts smooth shortening. The frequency of the oscillations we have observed appears to be determined only by the translation velocity of the fibre at the point observed, and not by the rate of change of sarcomere length. The latter is determined by the velocity of the moving end of the fibre, and was found to be very nearly constant along the length of the fibre, exhibiting only minor random variation.

The scatter in the data of Fig. 1 results, to a large extent, from errors in frequency estimation. With laser diffraction, steps appeared most often in areas of the fibre giving less than optimum signal quality and could not be found in most fibres. It was difficult to obtain cascades of clear steps throughout the length change. The PLL almost invariably produced regular cascades of steps, and frequency estimation was correspondingly accurate. Recent reports[4,10] have also noted the greater abundance and regularity of steps with the PLL. Sarcomere length records were usually repeatable over multiple 'contractions' as in previous experiments[1,3,11].

In search of a mechanism which might generate these oscillations, the first-order diffraction line was monitored during sarcomere length changes. As the duration of a pause could be extended from <50 ms to >1 s simply by decreasing the length

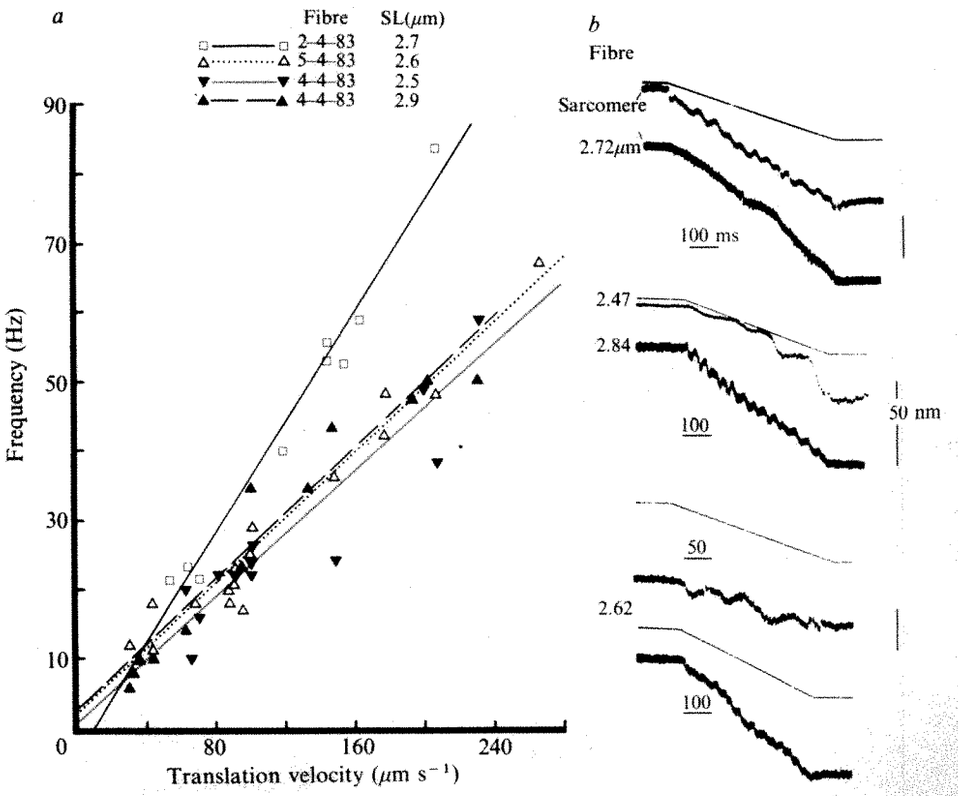

Fig. 1 *a*, Step frequency plotted against translation velocity; results from laser diffraction[8], beam diameter 100–200 μm. The lines were fitted by least-squares regression, $r = 0.94$–0.98. Frequency was measured by obtaining cascades of steps throughout the length change, and counting the number of cycles throughout. Translation was measured by following the movement of natural markers during the length change. Translation velocity was varied in two ways (see text). Method (1) was used on fibres of 2-4-83 and 4-4-83 and a combination of (1) and (2) on fibre of 5-4-83. *b*, Typical records from graph data. Upper records: translation velocity varied by studying two different points on the fibre, muscle release unchanged. The lower sarcomere length trace of each pair was obtained from the point nearer to the moving end of the fibre (note the high frequency of this record). Middle records: both the sarcomere length and the point along the fibre were changed; release velocity constant. Lower records: the position along the fibre, and the velocity and amplitude of length change varied from the same initial sarcomere length. All experiments were done on single anterior tibialis fibres of *Rana temporaria*, at 6–8 °C, in standard Ringer's solution. All fibres gave reproducible tetanic force records before and after the experiment. Fibres were viewed at all times through a ×40 water immersion objective (Zeiss, n.a. 0.75).

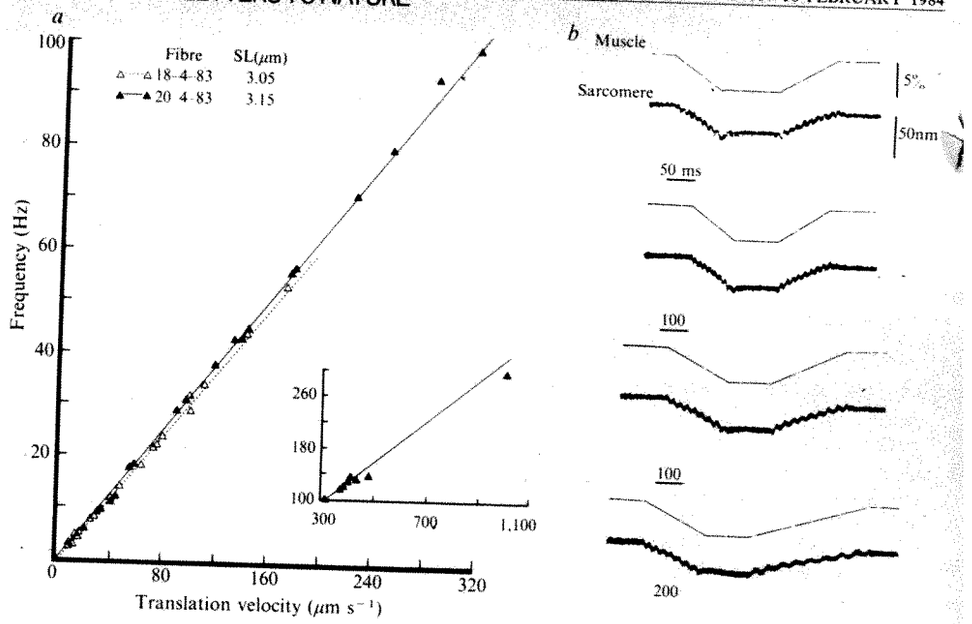

Fig. 2 *a*, Step frequency plotted against translation velocity. Inset shows continuation of data from fibre of 20-4-83. The lines were fitted by least-squares regression, $r = 1.0$ in both cases. Sarcomere length was determined by an on-line, direct imaging technique[9], which uses a PLL to measure the spatial frequency of the microscopic image of the striation pattern, over 12–14 sarcomeres in series (30–40 × 5 × 5 μm). Representative records are shown in *b*; the translation velocity was varied by changing the velocity of release and stretch (fibre of 20-4-83). The data for 18-4-83 were derived from changing the velocity of release/stretch, and by moving the sensor along the fibre. The data points at 18, 22, 29, 32, 34 and 53 Hz were obtained by method (1) (see text), with all sarcomeres shortening at the same velocity.

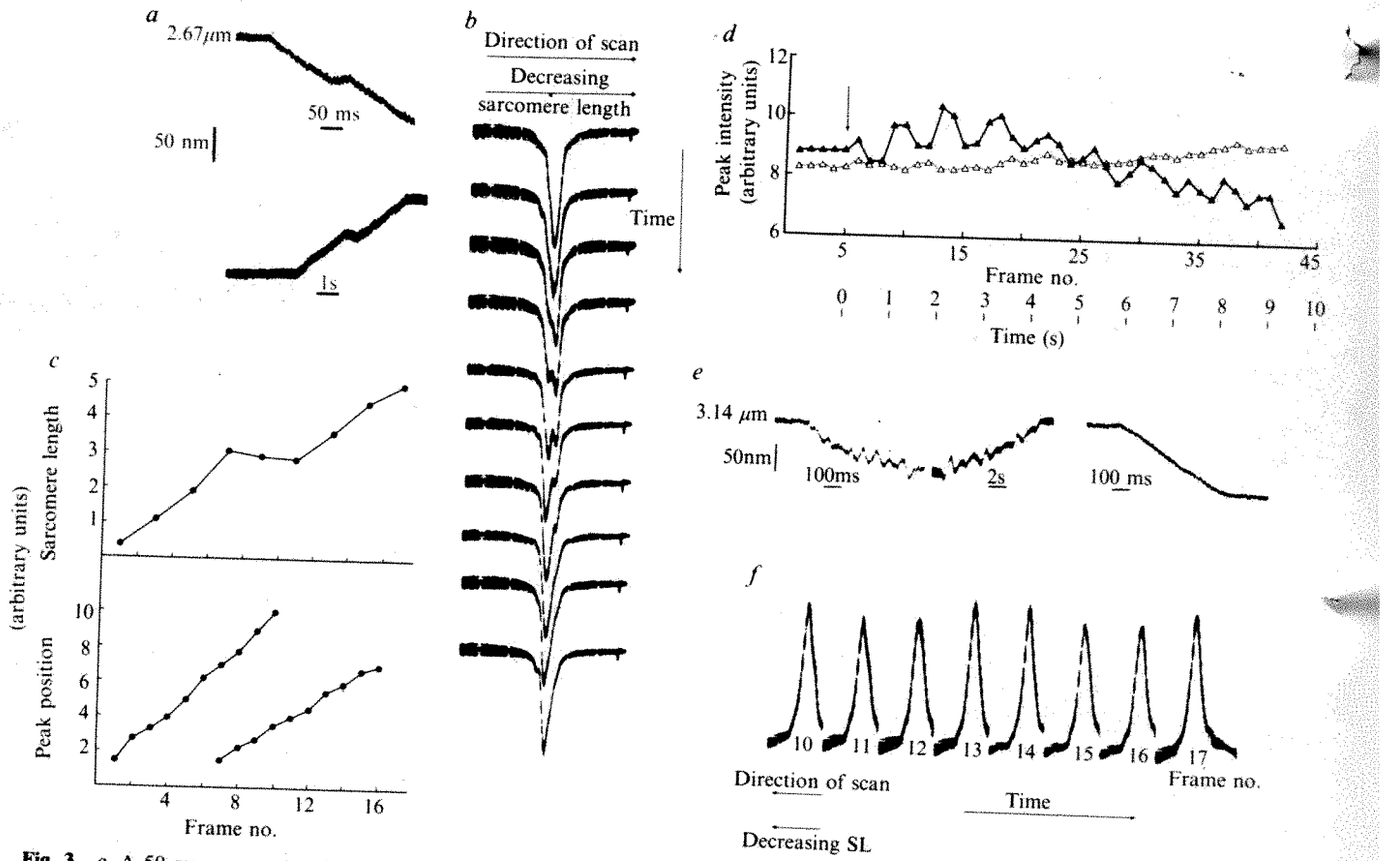

Fig. 3 *a*, A 50-ms pause, extended on the restretch to 1 s by slowing the length change. *b*, The first-order diffraction peak, as seen by the photodiode array, photographed at 4 frames per s during the extended pause. *c*, Sarcomere length, and the position of the two peaks of the first-order diffraction line (relative to an arbitrary reference line) plotted against time. Sarcomere length was plotted by electronically scanning the photodiode array from left to right (once every 256 μs), integrating the light intensity, and computing the distance along the array at which 50% of the integral was reached. The 50% integral value from each scan was carried over to the next, and logic circuits were switched when the integral reached this value—the sarcomere length. Thus, each sarcomere length computation used the first-order light intensity value from the previous scan. It was assumed that the intensity does not change significantly from scan to scan. This assumption is valid for most purposes, but when used close to the resolution limit, as here, the errors may be significant. In this case, the appearance of a secondary peak increased the area under the curve at long sarcomere lengths, switching the logic prematurely, and resulting in an apparent halt in sarcomere lengthening, despite the fact that both peaks moved continuously, as shown in *c*. *d–f* Shows a second example in which the steps/oscillations are the result of periodic intensity changes in an otherwise smooth, near-symmetrical first-order diffraction line. In *d*, the peak intensity of the diffraction line is plotted against time for data taken during the slow restretch of the release/stretch sequence illustrated in the left-hand and centre records of *e*. Note how symmetrical the sarcomere length changes are, despite the difference in time base. The number of intensity change cycles equals the number of sarcomere length oscillations, and the earlier, larger sarcomere length changes on the stretch are associated with the greatest intensity changes. Consistent with the method of sarcomere length determination, an increase in intensity leads to an overestimate of sarcomere length. Frames 10–17 of the diffraction line are shown in *f*. For comparison the open triangles in *d* are from data taken during a typical smooth sarcomere length change (*e*, right-hand record).

change velocity, it was possible to photograph the diffraction line during a prolonged pause (Fig. 3*a*). Here the apparent pause can be accounted for by the formation of a secondary peak (Fig. 3*b*), leading to a mis-computation of sarcomere length, as the method is based on the assumption that there are no significant changes in peak intensity and symmetry between computations (see Fig. 3 legend). Small changes in first-order intensity alone may also produce steps (Fig. 3*d–f*). The analyses in Fig. 3 are representative of a total of 14, from three fibres, at sarcomere lengths of 2.5–3.9 μm. In all cases steps were associated with detectable changes in the diffraction line.

Thus, changes in intensity and the formation of secondary peaks in the first-order line are possible causes of steps/oscillations. Both phenomena might arise from Bragg diffraction[2,12], while myofibrillar sliding, resulting in periodic variation in myofibrillar skew, might also contribute to intensity fluctuations[13,14]. Diffraction steps may therefore have several sources, explaining their often irregular appearance. The slope of the regression line for the PLL data indicates that one oscillatory cycle corresponds to the translation of one sarcomere past a given point in the optical field. This, and the regular appearance of PLL steps, suggests a single mechanism of generation, inherent in the method of sarcomere length determination.

Due to the rapid time course of a twitch, attempts to correlate step frequency with translation in active contractions would be difficult. However, one can estimate the upper and lower limits of translation velocity if fibre length and the extent and time course of internal shortening are known; all are readily available from our own and published data. From these calculations, translations of <20–70 μm in 50–150 ms might be expected; very similar values were calculated by Jacobson *et al.*[15]. From Figs 1 and 2, frequencies of <20–1,000 Hz are predicted, that is, half periods or pause durations of 1 to >25 ms. This range is consistent with that of published durations[1,3–7,11,15]. The wide variety of step patterns observed in active contractions might be expected, because translation will be random relative to that occurring during the linear length changes imposed on resting fibres. Without studying active contractions, the above must remain speculative.

Many published properties of the stepwise shortening phenomenon can be explained on the basis of a translation-dependent oscillation. The increase in pause duration observed under: increased load[11], decreased sarcomere length (and concomitant decrease in shortening velocity)[11] and near the peak of a twitch[3,11], can all be accounted for by the decrease in internal movements in these conditions. Decreasing translation velocity would decrease the oscillation frequency and hence increase pause duration.

That step generation may result from changes in the diffraction pattern is consistent with the observation that steps are more common in cardiac than in skeletal preparations[1,3]; it is well known that cardiac muscle gives poorer diffraction patterns.

Our studies revealed other features suggesting a non-physiological origin for steps. A 20 °C change in temperature had no effect on steps during passive length changes. The occurrence of steps at sarcomere lengths around 4.0 μm, indistinguishable from those at 2.4 μm (ref. 7), clearly indicates that steps do not result from acto-myosin interaction, unless there is a substantial change in filament length during the passive stretch of sarcomeres beyond 3.65 μm.

We thank Dr A. M. Gordon and Professor A. F. Huxley for their comments on the manuscript and Drs A. M. Gordon, M. E. Cantino and F. Fristoe for many stimulating and helpful discussions. This work was supported by postdoctoral fellowships from the SERC (J.D.A.), the Rotary Foundation (R.B.) and the AHA of Washington (J.W.L.).

Glycophorin is linked by band 4.1 protein to the human erythrocyte membrane skeleton

Richard A. Anderson* & Rex E. Lovrien

Department of Biochemistry, University of Minnesota, 140 Gortner Laboratory, St Paul, Minnesota 55108, USA

The cytoskeleton underlying the membrane of erythrocytes is thought to control changes in cell shape such as the diskocyte to the echinocyte. Since the binding of lectins to the transmembrane protein glycophorin blocks the cell shape change, we have proposed that the cytoplasmic end of glycophorin is linked to the cytoskeleton[1]. Here we show that the cytoskeletal protein known as band 4.1 specifically associates with the cytoplasmic domain of glycophorin on inside-out erythrocyte membrane vesicles and also with glycophorin reconstituted into phosphatidylcholine vesicles. The binding of band 4.1 to glycophorin is saturable and inhibitable by antibodies which bind specifically to the cytoplasmic domain of glycophorin. We therefore believe that band 4.1 protein provides the link between glycophorin and the cytoskeleton.

Glycophorin was isolated[2,3], desialated and incorporated into phosphatidylcholine vesicles (dGP-vesicles) by dialysis of a mixed micellar solution of octyl glucoside, phosphatidylcholine and desialoglycophorin[4]. The resulting dGP-vesicles are large enough to be easily sedimented using the ultracentrifuge. It is this property which allows proteins that associate with the vesicles to be separated from proteins that remain free in solution.

Membrane skeletal proteins were sequentially solubilized from isolated erythrocyte membranes[5] by extracting with buffered solutions of various ionic strengths[6,7]. The membrane skeletal extracts are enriched in specific proteins (refs 7, 8 and Fig. 1). The extracted proteins were combined with dGP-vesicles and incubated at 37 °C. The dGP-vesicles with bound proteins were then sedimented in the ultracentrifuge and the supernatant was removed. Protein from the vesicle pellet was analysed by SDS-polyacrylamide gel electrophoresis (SDS-PAGE, Fig. 1). As a control an equivalent amount of phosphatidylcholine vesicles (PC-vesicles) prepared identically to dGP-vesicles but without glycophorin were combined with membrane skeletal proteins and analysed in an identical fashion (Fig. 1). The SDS-PAGE shows that only one membrane skeletal protein (band 4.1) specifically bound to the dGP-vesicles. Although several proteins bound nonspecifically to both kinds of vesicles, only band 4.1 showed a large relative increase in the amount bound to dGP-vesicles. Quantification of the amount of band 4.1 bound[8] shows that dGP-vesicles bound 16-fold more band 4.1 (4.7 μg) than did PC-vesicles (0.3 μg) (Fig. 1, lanes *f*, *g*).

In a similar experiment, membrane skeletal proteins extracted with 1 M KCl (mainly spectrin, bands 2.1, 6, 4.9 and 4.1) were

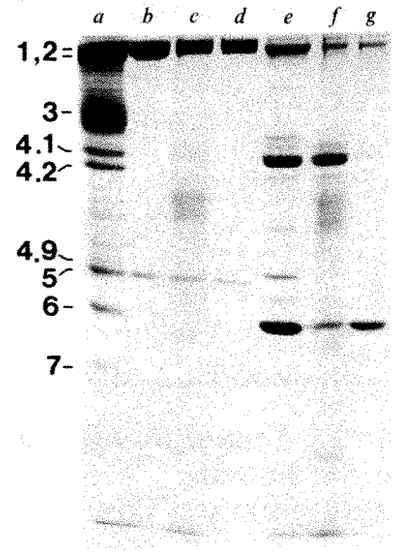

Fig. 1 SDS-PAGE of membrane skeletal protein extracts and membrane skeletal proteins bound to dGP- and PC-vesicles. Samples are: *a*, membrane proteins, 25 μg; *b*, low ionic strength extract, 7 μg protein; *c*, dGP-vesicles + low ionic strength extracted protein; *d*, PC-vesicles + low ionic strength extracted protein; *e*, 1 M KCl extracted protein, 14 μg protein; *f*, dGP-vesicles + 1 M KCl extracted protein; *g*, PC-vesicles + 1 M KCl extracted protein.

Methods: Isolated glycophorin[2] (15 mg ml^{-1}) was desialated with *Clostridium perfringens* neuraminidase (0.1 U ml^{-1}) at *p*H 5.0 for 1 h at 37 °C. The desialoglycophorin was then reconstituted into large phosphatidylcholine vesicles[4]. To a thin film of phosphatidylcholine was added octyl-β-D-glucopyranoside (octyl glucoside) and desialoglycophorin in water. The resulting mixed micellar solution of phosphatidylcholine (36 mM), octyl glucoside (340 mM) and desialoglycophorin (0.12 mM) was extensively dialysed against 140 mM NaCl, 5 mM sodium phosphate, 3.0 mM NaN_3, 0.5 mM DL-dithiothreitol (DTT) at *p*H 7.6. The solution of dGP-vesicles was applied to a 2.0 × 38 cm Sepharose CL-4B column equilibrated with 130 mM KCl, 10 mM NaCl, 5 mM sodium phosphate, 3 mM NaN_3, 1 mM EDTA, 0.5 DTT at *p*H 7.6 (130 mM KCl buffered). Vesicles with reconstituted desialoglycophorin eluted in the column void. Control vesicles (PC-vesicles) were prepared identically, except without desialoglycophorin. Membrane skeletal proteins were extracted from isolated erythrocyte membranes using: (1) low ionic strength buffer to extract spectrin and actin and (2) 1 M KCl buffer to extract primarily bands 2.1, 4.1, 6 and residual spectrin (refs 5 and 6 describe the complete buffers). The cytoskeletal protein solutions were dialysed against 130 mM KCl, 10 mM NaCl, 5 mM sodium phosphate, 0.5 mM DTT, 0.1 mM phenylmethylsulphonyl fluoride (PMSF) and then combined with dGP- and PC-vesicles. The final concentration of membrane skeletal protein was 20 μg ml^{-1}; glycophorin concentration was 50 μg ml^{-1}. The concentration of phosphatidylcholine was 250 μg ml^{-1} for both dGP- and PC-vesicles. Solutions of membrane skeletal proteins and vesicles were incubated at 37 °C for 20 min then centrifuged at 150,000*g* for 1 h at 2 °C. The vesicle pellets were solubilized in sample buffer, applied to a SDS-PAGE and developed according to Laemmli's method[22].

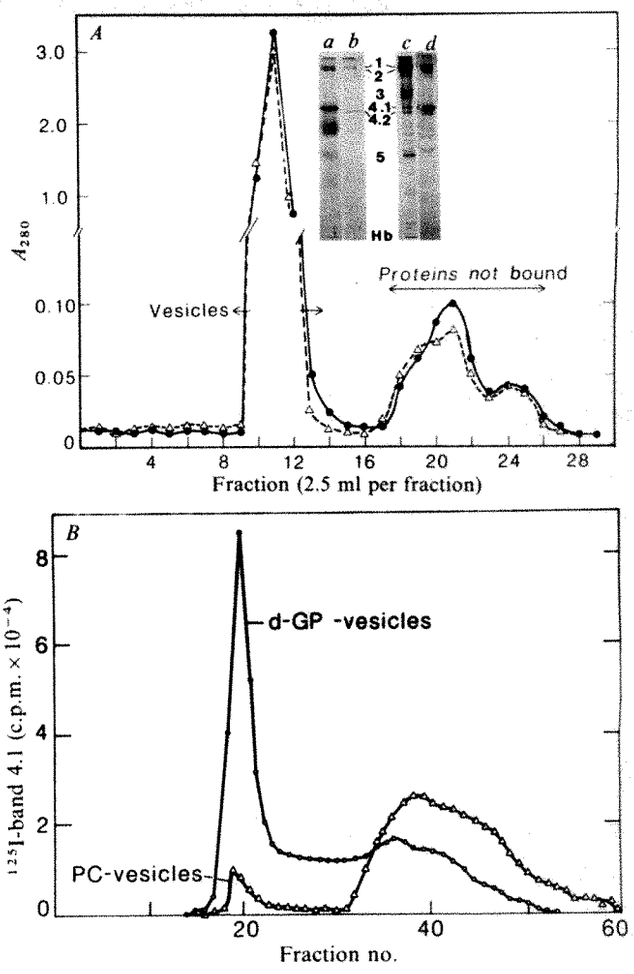

Fig. 2 *A*, Band 4.1 remains bound to dGP-vesicles (△) after chromatography of Sepharose CL-4B, but not to PC-vesicles (●). The samples on SDS-PAGE are: *a*, proteins bound to dGP-vesicles; *b*, proteins bound to PC-vesicles; *c*, 20 μg of total membrane proteins; *d*, 12 μg of protein extracted from membranes with 1 M KCl buffer. *B*, Elution profile of ^{125}I-protein 4.1 which was combined with dGP-vesicles (○) or with PC-vesicles (△).

Methods: *A*, The 1 M KCl extracted membrane skeletal proteins (100 μg ml^{-1}) were combined with dGP-vesicles (100 μg ml^{-1} glycophorin) or PC-vesicles. The solutions, after incubation at 37 °C for 20 min, were applied to a 2 × 38 cm Sepharose CL-4B column. Vesicles eluted from the column in the void together with bound protein. The vesicles which eluted from the column were concentrated by centrifugation (as in Fig. 1) and the protein in the vesicle pellet was analysed by SDS-PAGE. *B*, Purified band 4.1 was labelled with ^{125}I Bolton–Hunter reagent[6,7]. The ^{125}I-labelled band 4.1 (50 μg ml^{-1}) was combined with dGP-vesicles (200 μg ml^{-1} glycophorin) or an equivalent amount of PC-vesicles; after incubation the solution was applied to a 2 × 38 cm Sepharose CL-4B column as above. The elution profile was monitored by following the ^{125}I label. The vesicle peak was determined by turbidity measurements at 280 nm.

combined with either dGP-vesicles or PC-vesicles. Following incubation at 37 °C the vesicle solutions were applied to a Sepharose 4B-CL column. Both kinds of vesicles eluted from the column in the void and were completely separated from proteins which were not bound (Fig. 2*A*). The vesicles were then analysed by SDS-PAGE as above, comparing the proteins remaining bound to dGP-vesicles (Fig. 2*A*, lane *a*) with proteins binding to PC-vesicles (lane *b*). In these conditions dGP-vesicles retained about 40-fold more band 4.1 than did PC-vesicles: 3.9 μg compared with <0.1 μg of bound band 4.1, respectively. Spectrin was the only other protein which bound to the vesicles. The dGP-vesicles also retained more spectrin than did PC-vesicles, possibly due to the spectrin–band 4.1 association[6,7].

To establish that band 4.1 associates specifically with dGP-vesicles without participation of other proteins, band 4.1 was purified and labelled with ^{125}I using the Bolton–Hunter reagent[7,8]. Purified band 4.1 showed the characteristic major doublet on Laemmli SDS-PAGE, with two minor bands[9], above and below band 4.1, representing about 15% of the total applied proteins. All three bands are immunologically cross-reactive with anti-band 4.1 antibody[9]. The ^{125}I-labelled band 4.1 was combined with dGP-vesicles or PC-vesicles and the vesicle solutions were applied to a Sepharose 4B column. Elution of band 4.1 was monitored by following the ^{125}I label. The elution profile of band 4.1 from the Sepharose column (Fig. 2*B*) demonstrates that a large fraction (37%) of the ^{125}I-band 4.1 remained bound

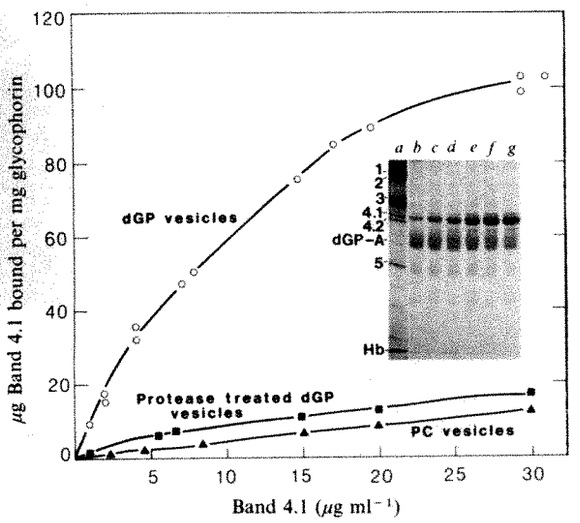

Fig. 3 Binding isotherms of native protein 4.1 to dGP-vesicles (○), protease-treated dGP-vesicles (■) and PC-vesicles (▲). An SDS-PAGE of band 4.1 bound to dGP-vesicles is shown. Samples are: *a*, 30 μg of total membrane protein; *b–g*, protein from the dGP-vesicle pellet, the band 4.1 concentration being varied over 2–30 μg ml^{-1}.

Methods: The binding isotherms were determined by combining dGP-vesicles (60 μg ml^{-1} glycophorin) with increasing amounts of native band 4.1. The solutions were incubated as described in Fig. 2 legend, followed by centrifugation of the dGP-vesicles with bound protein. The resulting vesicle pellet was prepared for SDS-PAGE as in Fig. 1. To the SDS-PAGE (separate lanes) was applied between 1 and 10 μg per lane of ultra-pure bovine serum albumin (BSA) as a protein standard. The amount of band 4.1 in each lane of the SDS-PAGE was quantitated by extracting and quantitating the Coomassie blue stain. The amount of dye bound was compared with a standard curve generated with known amounts of BSA applied to the same SDS-PAGE[8]. From the standard curve the amount of band 4.1 bound was determined as a ratio of μg band 4.1 bound per mg glycophorin. The SDS-PAGE shows that the desialoglycophorins all migrate well below band 4.1 on the SDS-PAGE and thus do not interfere with dye extraction from the 4.1 band; ~70 μg per lane glycophorin was applied. Binding is plotted in terms of μg band 4.1 bound per mg reconstituted glycophorin versus the total band 4.1 concentration in μg ml^{-1} (○). Nonspecific binding of band 4.1 was determined using an equivalent amount of phosphatidylcholine vesicles without incorporated desialoglycophorin (▲). Desialoglycophorin reconstituted into phosphatidylcholine vesicles was cleaved with a 20:1 weight ratio of desialoglycophorin to both trypsin and chymotrypsin at 37 °C for 4 h. Protease activity was destroyed by addition of 0.1 mM diisopropyl fluorophosphate (DFP). Binding of band 4.1 to protease-treated dGP-vesicles is plotted in terms of μg band 4.1 bound per mg of original glycophorin (■).

and co-eluted with the dGP-vesicles. In contrast, only a small fraction (2.5%) of the ^{125}I label co-eluted with PC-vesicles. Analysis of these vesicles by SDS-PAGE showed that 85–90% of the ^{125}I label bound to dGP-vesicles migrated with band 4.1. The majority (70–80%) of the ^{125}I label bound to PC-vesicles migrated with the small molecular weight minor protein band on SDS-PAGE, not with band 4.1. The dGP-vesicles in these conditions retained 60-fold more band 4.1 than did an equivalent amount of PC-vesicles.

To demonstrate further that band 4.1 associates specifically with reconstituted glycophorin, a binding isotherm of band 4.1 to dGP-vesicles was determined. The binding isotherm (Fig. 3), determined using native band 4.1, illustrates that the association of 4.1 with dGP-vesicles is saturated at ~110 μg of band 4.1 bound per mg glycophorin. The binding constant is $1.1 \pm 0.4 \times 10^7$ M^{-1}. Nonspecific binding was determined using an equivalent amount of PC-vesicles (Fig. 3). The band 4.1 binding sites on dGP-vesicles are removed by proteolysis with trypsin and chymotrypsin, indicating that band 4.1 binding requires a protease-sensitive peptide (Fig. 3).

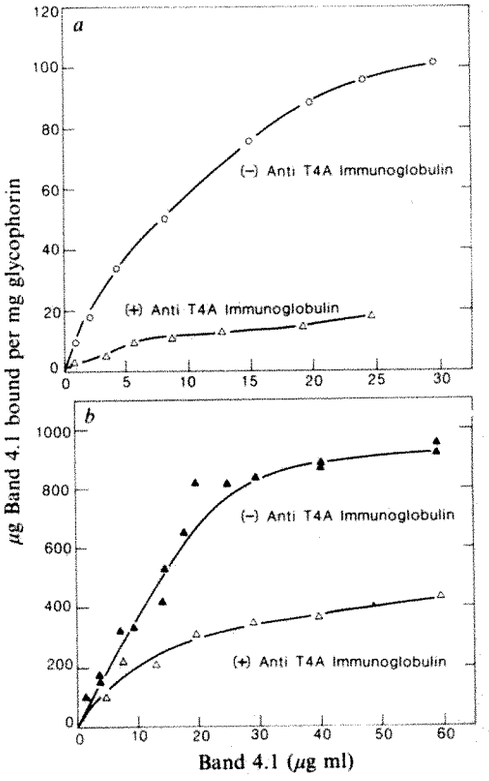

Fig. 4 *a*, Binding isotherm of ^{125}I-Bolton–Hunter labelled band 4.1 to dGP-vesicles (○) and inhibition of ^{125}I-band 4.1 binding to dGP-vesicles by anti-glycophorin cytoplasmic domain antibody (anti-T4A antibody) (△). *b*, Binding of ^{125}I-band 4.1 to IOVs (▲) and inhibition of ^{125}I-band 4.1 binding to IOVs using anti-T4A antibody (△).

Methods: *a*, Band 4.1 (200 μg) was labelled with 0.2 mCi of ^{125}I-Bolton–Hunter reagent[7]. Labelled band 4.1 (0.8 mCi mg^{-1}) with full biological activity was isolated by binding ^{125}I-band 4.1 to dGP-vesicles, separating the biologically active ^{125}I-band 4.1 from inactive ^{125}I-band 4.1 by centrifugation or chromatography as in Fig. 2*B* and then eluting the bound ^{125}I-band 4.1 from the dGP-vesicles with 1 M KCl buffer. The ^{125}I-band 4.1 was dialysed against 130 mM KCl buffer and diluted with cold band 4.1 to a specific activity of ~1 μCi per mg. This ^{125}I-band 4.1 was used for band 4.1 binding to dGP-vesicles. (Sheep antiserum raised against the cytoplasmic domain of glycophorin A[11] (cyanogen bromide fragment 2) was a gift from Drs Marchesi and Furthmayr, Yale University.) Pure antibody was isolated by affinity chromatography on the T4A(B) tryptic fragment of glycophorin A which was coupled to Sepharose-4B with cyanogen bromide[23]. To inhibit band 4.1 binding to dGP-vesicles, the vesicles were pretreated with antibody at a 1:1 antibody/glycophorin molar ratio. However, as glycophorin is asymmetrically incorporated into phospholipid vesicles it is likely that at most only 20% of the glycophorins have available cytoplasmic domains[4], thus a 5:1 molar ratio is more likely. At such a molar ratio of antibody to glycophorin cytoplasmic domain the antibody binding sites are likely to be saturated. *b*, IOVs were prepared according to refs 14 and 15. The amount of glycophorin in these IOVs was determined by assaying for sialic acid[24], assuming 70% of total sialic acid is attached to glycophorins and that glycophorins are 30% sialic acid by weight. The concentration of glycophorin in IOVs used for binding was 4 μg ml^{-1} (30 μg ml^{-1} total protein). The amount of bound ^{125}I-band 4.1 was determined by counting the vesicle pellet. Inhibition of band 4.1 binding to IOVs was accomplished by using a fivefold antibody excess as above.

Reconstitution of glycophorin into phosphatidylcholine vesicles results in an asymmetric orientation of glycophorin across the lipid bilayer. The majority of the carbohydrate-bearing domains are located on the outside surface of the vesicles[4,10]. Such asymmetric orientation corresponds well with the binding isotherm, as asymmetric orientation of glycophorin would result in the low band 4.1:glycophorin stoichiometry that is observed

at saturation, if band 4.1 associates with the cytoplasmic domain of glycophorin.

Further evidence that band 4.1 associates with the cytoplasmic domain of glycophorin is provided by antibodies directed against the cytoplasmic domain of glycophorin A. These antibodies were used to inhibit band 4.1 binding to vesicles containing glycophorin. Antiserum was raised in sheep immunized against the cyanogen bromide fragment (CB2) containing the cytoplasmic domain of glycophorin A (ref. 11). Pure antibody specific for the cytoplasmic domain of glycophorin was isolated by affinity chromatography using the T4A fragment of glycophorin A[11,12] as the affinity ligand attached to Sepharose 4B. The T4A fragment is the major portion of the glycophorin A cytoplasmic domain[11,12].

Band 4.1 binding and inhibition of binding was monitored with ^{125}I-labelled band 4.1 (refs 7, 8). The binding isotherm of ^{125}I-band 4.1, with full biological activity towards dGP-vesicles (Fig. 4*a*), compares well with that determined using native band 4.1 (Fig. 3). Anti-T4A antibody, preincubated with dGP-vesicles before addition of protein 4.1, blocked 70–80% of the band 4.1 binding sites on dGP-vesicles. However, when pure glycophorin A was reconstituted into phosphatidylcholine vesicles, band 4.1 specifically bound to these vesicles and anti-T4A antibody completely inhibited (>90%) the band 4.1 binding. Moreover, when glycophorin B was reconstituted into phosphatidylcholine vesicles, band 4.1 specifically bound to these vesicles, but the binding was not inhibited by anti-T4A antibody (unpublished results). Such behaviour is expected, as anti-T4A antibody does not cross-react with glycophorin B[13].

Inverted erythrocyte membrane vesicles (IOVs) were isolated from fresh erythrocyte membranes[5] and stripped of membrane skeletal proteins[14,15]. The stripped IOVs were used to establish a binding isotherm of ^{125}I-labelled band 4.1 to the cytoplasmic surface of the erythrocyte membrane (Fig. 4*b*). The binding isotherm shows saturation and approximately the same binding affinity as band 4.1 binding to dGP-vesicles. At saturation 880 μg of band 4.1 are bound per mg of glycophorin. Pretreatment of stripped IOVs with anti-T4A antibody blocked at least 60% of the band 4.1 binding sites (Fig. 4*b*). Only the cytoplasmic domain of glycophorin A was blocked by anti-T4A antibody. Thus, at least 60% of the band 4.1 binding sites are contributed by glycophorin A. The remaining binding sites may be contributed by the cytoplasmic domains of glycophorin B and glycophorin C which would still be available for binding[16]. Thus in En(−a) erythrocytes, which are thought to be devoid of glycophorin A[17], glycophorins B and C could still contribute enough membrane attachment sites to accommodate all of the protein 4.1 molecules in the cell.

The above results provide evidence that band 4.1 specifically associates with the cytoplasmic domain of glycophorin A, and also possibly glycophorin B. Previously, band 4.1 was shown to associate tightly with spectrin[6,7]. The binding site for band 4.1 on spectrin is located in close proximity to the spectrin–actin association site[6,7]. Furthermore, association of band 4.1 with spectrin markedly enhanced the interaction between spectrin and actin protofilaments[18–21]. As such, the effect of band 4.1 on the spectrin–actin association could have a regulatory role in controlling the dynamics of membrane skeleton change. Control of membrane skeletal change may in turn be mediated by externally bound lectins via the interaction between transmembrane glycophorin and band 4.1.

Activation of the mouse cellular Harvey-*ras* gene in chemically induced benign skin papillomas

Allan Balmain, Martin Ramsden, George T. Bowden* & John Smith

Beatson Institute for Cancer Research, Garscube Estate, Bearsden Road, Glasgow G61 1BD, UK

An important feature of the development of many human and animal tumours is the appearance of pre-malignant benign lesions, some of which undergo further changes during progression to malignancy[1–4]. Many of the currently accepted concepts of multi-stage carcinogenesis have been developed using an experimental model based on the chemical induction of tumours in mouse skin[3,4]. In this system, many of the pre-malignant papillomas which arise are promoter-dependent, and appear to regress if promoter treatment is interrupted, whereas others progress to form autonomous benign lesions and, in some cases, malignant carcinomas[5]. Although the number and nature of the events leading to malignancy are not known, DNA transfection experiments have led to the identification of several genes which may be qualitatively altered in tumour cells (see ref. 6 for review). We have previously shown that DNA from transplantable mouse skin carcinomas induced by chemical carcinogens has the ability to transform NIH/3T3 cells, and that the gene responsible for the transformation is an activated form of the mouse cellular Harvey-*ras* gene (c-*ras*^{H})[7]. We have now investigated the stage of carcinogenesis at which the proto-oncogene acquires transforming activity. We demonstrate that primary papillomas induced by chemical carcinogens in two different mouse strains have an activated c-*ras*^{H} gene. This constitutes the first report of a benign tumour which contains DNA with detectable transforming activity. In addition, steady-state levels of c-*ras*^{H} gene transcripts are elevated in the papillomas as compared with normal epidermis.

Both benign and malignant skin lesions can be induced in mouse skin by sequential treatment with initiators and promoters of carcinogenesis[3,4]. Tumours were induced in the dorsal skin of Sencar mice, a strain bred for sensitivity to chemical carcinogens[8,9], by initiation with dimethylbenzanthracene (DMBA) followed by multiple treatments with the tumour promoter 12-O-tetradecanoyl-phorbol-13-acetate (TPA). In this strain individual papillomas and carcinomas are large enough to provide sufficient DNA for analysis by transfection into NIH/3T3 cells. Table 1 shows the results obtained when several primary tumours were tested for transforming activity. Of five DNA samples prepared from papillomas, four showed positive results in transfection assays. Similarly, two out of three carcinomas induced foci of transformed cells in NIH-3T3 fibroblasts. In the same series of experiments, DNA from normal

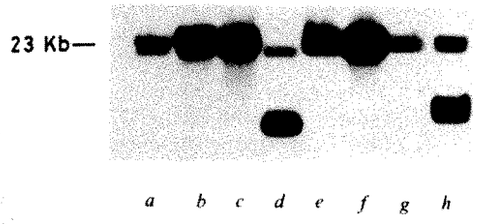

Fig. 1 Southern blot analysis of sequences related to the v-*ras*^{H} gene in NIH/3T3 transformants induced by primary mouse papilloma and carcinoma DNAs. The DNAs were from the following sources: *a*, NIH/3T3; *b*, NIH/3T3 transformant obtained by transfection with primary carcinoma DNA; *c–f*, *h*, transformants induced by different papilloma DNAs; *g*, spontaneously arising transformant.

Methods: Tumours were induced on the dorsal skins of Sencar or NMRI mice by sequential treatment with DMBA and TPA[3,4]. High molecular weight DNA was isolated as previously described[7]. DNA (20 μg) from NIH/3T3 transformants was digested with *Eco*RI, electrophoresed through a 1% agarose gel, blotted onto nitrocellulose and hybridized with a nick-translated v-*ras*^{H} specific probe (BS9)[22]. Blots were washed to a final stringency of 0.5 × SSC at 65 °C and exposed to Kodak XAR5 film with intensifying screens at −70 °C.

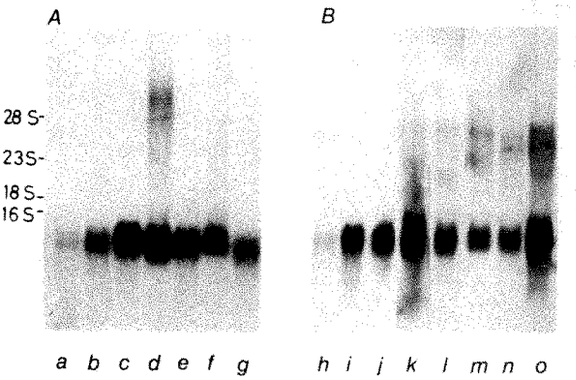

Fig. 2 *A*, Northern blot of c-*ras*^{H} transcripts in primary tumours. Total cellular RNAs were isolated from the following sources: *a*, normal epidermis; *b*, TPA-treated epidermis; *c–e*, individual papillomas from Sencar mice; *f*, pooled small papillomas from NMRI mice; *g*, Sencar carcinoma. *B*, Transcripts of c-*ras*^{H} sequences in NIH/3T3 transformants. Sources of the RNA were: *h*, NIH/3T3 cells; *i*, *j*, NIH/3T3 transformants induced by transplanted NMRI carcinoma DNA[7]; *k–n*, transformants induced by papilloma DNA; *o*, transformant induced by primary carcinoma DNA.

Methods: Frozen tumours or epidermis were ground in liquid nitrogen and lysed in 5 M guanidinium thiocyanate, 50 mM Tris-HCl (*p*H 7.0), 50 mM EDTA and 5% (v/v) 2-mercaptoethanol. Total cellular RNA was isolated from the lysate by centrifugation through a 5.7 M CsCl, 50 mM EDTA (*p*H 7.0) cushion, followed by ethanol precipitation. Aliquots (10 μg) of RNA were heated to 60 °C for 5 min in 50% deionized formamide, 2.2 M formaldehyde, 20 mM MOPS buffer, cooled rapidly, electrophoresed through 1% agarose gels in MOPS buffer (20 mM morpholinopropanesulphonic acid, 5 mM Na acetate, 1 mM EDTA *p*H 7.0), blotted onto nitrocellulose and hybridized to the ^{32}P-labelled v-*ras*^{H}-specific probe.

epidermis or from epidermis induced to proliferate by a single treatment with TPA failed to induce any stable transformants. Preliminary experiments using NIH mice (A.B. and J.S., unpublished results) also suggest that chronic treatment with TPA (three times weekly for 7 weeks) does not cause activation of transforming genes to a level detectable by the NIH/3T3 transfection assay. When primary transformants induced either by papilloma or carcinoma DNAs were grown in bulk culture, all the high molecular weight DNAs from these cells were positive when tested in second rounds of transfection into NIH/3T3 fibroblasts, indicating that a stable transforming gene was being transferred from both papillomas and carcinomas.

It has previously been noted that some papillomas can develop on the dorsal skin of Sencar mice after repeated promoter treatment but without any prior initiation[9]. This suggested that these mice may have a constitutive hereditary mutation which predisposes to the development of skin tumours. However, the lack of transforming ability of DNA from normal Sencar epidermis or from proliferating epidermis treated with TPA suggests that the transforming activity of the papilloma DNA cannot be attributed to a constitutive mutation in this mouse strain.

It remained possible, however, that Sencar papillomas might be abnormally 'advanced' in terms of tumour progression, and that transforming activity in other less sensitive mouse strains might only be acquired at the carcinoma stage. For this reason, papillomas were induced in NMRI mice and tested for transforming activity. Two independent DNA preparations from pooled small papillomas were positive in transfection assays, whereas liver or brain DNAs from the same inbred mouse strain were negative.

The transformation efficiencies with all of the primary tumour DNAs, including both papillomas and carcinomas, were about 5–10-fold lower than DNAs from the human EJ bladder carcinoma cell line[10–13] or a transplanted mouse carcinoma[7]. Similar low efficiencies have also been reported for a number of primary human tumours[14]. Note that the transforming efficiencies of all papilloma DNA samples were at least as high as that of the primary carcinomas, indicating that the results cannot be attributed to the presence of a small, histologically undetectable proportion of malignant carcinoma cells within some of the papillomas. In addition, the similar efficiencies obtained with the pooled small NMRI papillomas and the individual large Sencar papillomas demonstrate that papilloma size *per se* is not an important determinant of transforming gene concentration.

We have previously shown that transplanted carcinomas of NMRI mice contain an activated form of the c-*ras*^{H} gene[7]. To determine whether the *ras*^{H} gene is reproducibly activated during chemical carcinogenesis in the mouse skin model system, DNA from transformants induced by papilloma or carcinoma DNAs was isolated and analysed by Southern blotting and hybridization with a *ras*^{H}-specific probe. Newly acquired *ras*^{H} genes in transformed foci can be detected either by comparing band intensities with appropriate controls on genomic Southern blots or, more convincingly, by the presence of additional restriction fragments containing the extra gene(s) due to loss of a restriction site on integration. Figure 1 shows that DNAs from all of the foci induced by both papillomas and carcinomas exhibit a large increase in the intensity of hybridization with a *ras*^{H} probe, compared with normal 3T3 controls. In addition, some of the foci (lanes *d*, *h*) have an additional restriction fragment containing the extra *ras*^{H} genes, with the NIH/3T3 gene visible at the normal 23-kilobase (kb) position. No evidence for increased intensity of hybridization or additional restriction fragments were observed in spontaneously arising foci isolated from the same experiments (lane *g*). The amplification of the *ras*^{H} gene in the foci is not attributable to transfer of multiple copies from the orginal tumour cells, as these appear to contain only single copy *ras*^{H} sequences (data not shown). On probing the DNA of the foci with a Kirsten-*ras* specific probe, the intensity and pattern of hybridization in all foci was virtually identical to that in the 3T3 controls (data not shown), suggesting that the transfer and amplification had probably only occurred with the *ras*^{H} gene.

To determine whether c-*ras*^{H} transcripts are elevated in mouse skin tumours, RNA was prepared from a series of primary tumours and hybridized on Northern blots with a *ras*^{H}-specific probe. Figure 2*A* shows that the concentration of the major 1.4-kb transcript is increased in a series of papillomas relative to normal epidermis. This increase is apparent in individual Sencar papillomas (lanes *c–e*), in pooled small papillomas from NMRI mice (lane *f*), and, to a lesser extent, in a Sencar primary carcinoma (lane *g*). In view of the difficulties involved in estimating RNA concentrations by Northern blot hybridizations with a single probe, the blot shown in Fig. 2*A* has been re-hybridized with a cloned probe which is complementary to the ubiquitous, highly abundant cytoplasmic 7S RNA[15]. This demonstrated that

Table 1 Transforming activity of chemically induced skin papillomas and carcinomas

Source of DNA	Mouse strain	Samples tested	Positive samples‡
Normal epidermis	NIH/Swiss	2	0
	Sencar	2	0
TPA-treated epidermis	NIH/Swiss	1	0
	Sencar	1	0
Papilloma	Sencar	5*	4*
Carcinoma	Sencar	3	2
Papilloma	NMRI	2†	2†
Liver	NMRI	1	0
Brain	NMRI	1	0

Frozen tissues were ground in liquid nitrogen and DNA samples were prepared by resuspension in guanidinium thiocyanate and spinning through CsCl as previously described[7]. Transfections were carried out by adding 20 μg high molecular weight DNA to 25 cm^2 flasks seeded 24 h earlier with 3×10^5 cells per flask. Cells were maintained and foci scored as described earlier[7]. Epidermal cells were prepared from groups of 10–20 mice by scraping with a rounded scalpel after heating the skins in water at 55 °C for 30 s. Epidermal fractions were immediately frozen in liquid nitrogen.

* One DNA sample was prepared from three pooled papillomas.

† Both DNA samples were prepared from 8–10 pooled papillomas.

‡ Samples positive in transfection assay.

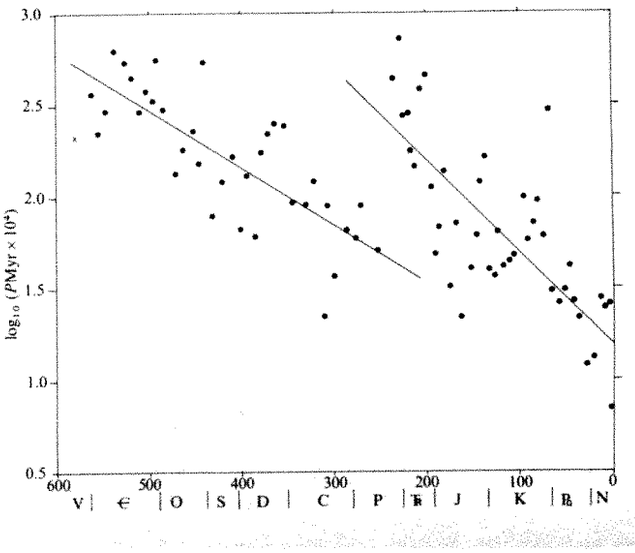
with the exception of the RNA from the papilloma in lane *e* and from the TPA-treated epidermis, approximately equivalent amounts of undegraded RNA were present in each lane (data not shown). Similar relative transcript levels have been found using RNA dot hybridization with probes specific for ras^H, 7S RNA and ribosomal RNA sequences (data not shown). We conclude that ras^H transcripts are elevated to a varying degree in different papillomas. The elevation is not due simply to an increase in the proportion of proliferating cells within the tumours because the hyperplastic epidermis induced by TPA does not contain substantially higher ras^H transcript levels.

An increase in the concentration of c-ras^H trancripts with respect to NIH/3T3 controls was also observed in transformed foci induced by transfection of DNA from papillomas or carcinomas (Fig. 2*B*). No reproducible correlation was found between steady-state concentrations of ras^H-related transcripts and the source of DNA used to induce the transformants.

The elevation of c-ras^H transcripts which is observed in the chemically induced primary tumours contrasts with the observations reported on the transcription of the equivalent human gene in the EJ/T24 bladder carcinoma cell line. Tabin *et al.*[16] compared c-ras^H transcript levels in EJ cells and in a normal human bladder cell line, and found no detectable differences. A possible explanation of this apparent contradiction is that the establishment of normal cells in culture leads to elevated ras^H gene expression, thus disguising any true increase during tumour development *in vivo*. In this context, it is interesting that elevated ras^H transcription has recently been found in several primary human tumours of the colorectum[17]. Alternatively, prolonged culture of tumour cells may result in lower levels of ras^H transcripts. It is also possible, if somewhat less likely, that differential extraction of RNA from basal or supra-basal cells could have occurred in our experiments, leading to artificially low ras^H transcript levels in control epidermis.

The number of independent genetic events involved in the transformation of a normal cell into a malignant tumour cell is unknown, but estimates range from two[18,19] to about seven[20]. It seems likely that the acquisition of dominant transforming properties by the DNA of malignant cells constitutes an important step in tumour progression. It has previously been speculated that this event occurs relatively late in tumour development[21]. This was based on the assumption that NIH/3T3 cells may already exist in an 'initiated' state, and require only one additional (late) event to acquire malignant properties. The data presented here, however, demonstrate that during chemical carcinogenesis *in vivo*, activation of the ras^H gene is a relatively early event. The proportion of papilloma DNAs which exhibited transforming activity (>85%) is much higher than the percentage of benign tumours which progress to carcinomas in this system (5–7%)[5]. This indicates that the mutational event which induces the transforming capacity of the DNA does not take place at the transition to malignancy, but already exists in most or all of the pre-malignant lesions.

Our results demonstrate that no significant differences are found between papillomas and carcinomas with respect to transforming activity of high molecular weight DNA and the degree of transcription of the activated c-ras^H gene. The progression of some, but not all, papillomas to malignant carcinomas may therefore be determined by another genetic event which does not involve the c-ras^H gene.



We thank Kl. Goerttler, H. Loehrke and T. Slaga for supplying tumour material, E. Hecker and G. Furstenberger for TPA, Gail Cole for technical assistance, and I. Kerr, G. D. Birnie and J. Paul for discussions and support. The Beatson Institute is supported by grants from the Cancer Research Campaign.

Errata

IN the letter 'A resetting of Phanerozoic community evolution' by L. M. Van Valen, *Nature* **307,** 50–52 (1984), the words 'It is therefore not feasible' in paragraph 5 should be replaced by 'This sort of analysis cannot be used'; and the reference to the 'Red Queen hypothesis' on page 51 should read 'Red Queen's hypothesis'. In addition, Fig. 1 was poorly reproduced: a correct version is shown below.

Lunar magnetism

IN a recent review of lunar palaeomagnetic investigations, Runcorn[1] has emphasized the possibility that an ancient core dynamo was the dominant source of the observed crustal magnetization by generating surface fields of 0.01–1.0 G in the $3.2–4.0 \times 10^3$ Myr time period. Major implications for lunar internal and dynamical history were discussed in part on the basis of both palaeomagnetic data and electromagnetic sounding data. Here we emphasize aspects of the lunar palaeomagnetic and electromagnetic sounding results which appear to be inconsistent with the core dynamo hypothesis; a more complete discussion can be found elsewhere[2].

First, various geophysical measurements limit the radius of a present-day lunar metallic core to a maximum of 400–500 km and do not require a metallic core of any radius. Therefore, the statement "evidence for an iron core in the Moon today (has) been found" (ref. 1) is somewhat misleading. Low-frequency electromagnetic sounding measurements for times when the Moon was in the solar wind or terrestrial magnetosheath[3,4] have been shown by Hobbs *et al.*[5], using inverse theory, to imply only an upper bound of 435 km on the radius of a possible metallic core; the data are equally consistent with a core radius of 0 km. Although Russell *et al.*[6], in an analysis of magnetometer records from periods when the Moon was in the lobes of the geomagnetic tail, obtained tentative evidence for a core with conductivity $\geq 10\ S\ m^{-1}$ and radius ≥ 400 km, a molten silicate core could equally well provide a conductivity of this magnitude so an iron core with conductivity $\geq 10^5\ S\ m^{-1}$ is not required. In addition, remaining questions about the possible effects of tail-lobe plasma on the induced moment measurements preclude acceptance of these results as definitive. Recent summaries of lunar seismic investigations conclude that seismic evidence for the existence of a metallic core is unresolved[7,8] with earlier suggestions of a possible molten core of radius ≤ 350 km continuing to depend on the interpretation of a single data point[9]. Other independent constraints are model-dependent to equal or greater extents as noted by Runcorn.

Anderson[10], using Busse's theory of planetary magnetism[11], has calculated that a lunar spin rate 20 times the present value combined with a fluid conducting core radius of 750 km would be necessary to produce surface palaeofields of 0.02 G, that is, approximately corresponding to minimum palaeointensities during the 3.2–4.0 Myr time period. To produce surface fields of ~1 G, corresponding to the high-field epoch discussed by Runcorn and Cisowski *et al.*[12], a core radius exceeding 1,000 km would be required. Therefore, assuming the first-order validity of Busse's model, the geophysical constraints on the radius of a metallic core summarized above are inconsistent with an iron core dynamo origin for lunar palaeomagnetism. In order to overcome these difficulties, Cisowski *et al.* have suggested a possible close approach of the Moon to the Earth at $\sim 3.8 \times 10^3$ Myr acting to amplify a marginal lunar dynamo according to a mechanism considered theoretically by Levy[13]. However, even accepting the latter hypothesis, it is doubtful that a core dynamo can explain all of the magnetization that is inferred from both orbital and sample studies to have occurred over a period exceeding 10^3 Myr. An additional mechanism is needed as has also been stressed by Anderson.

Circumstantial evidence for the identity of this mechanism comes from orbital magnetometer and electron-reflectance studies of the distribution of lunar magnetic anomalies and their correlation with surface geological features as well as from returned sample studies and surface magnetic field investigations. On the near side, most magnetic anomalies detected at low altitudes with the Apollo subsatellite magnetometers correlate with exposures of the Fra Mauro and Cayley Formations, primary and secondary basin ejecta materials[14]. Additional anomalies detected across part of the far side using the electron reflectance technique have been shown to occur peripheral to ringed impact basis where basin ejecta units are observed or are inferred to be present[15]. Two separate exposures of the Fra Mauro Formation peripheral to the Imbrium basin, separated by ~100 km, have been inferred to be magnetized in very different directions, indicating a local scale size for the magnetizing field[16]. High-amplitude orbital anomalies detected via both techniques generally correlate with surficial concentrations of apparently relatively young Reiner γ-type units which most probably have an impact-related origin[14,17–19]. In combination with the relatively high intrinsic magnetization levels that are characteristic of some returned breccias and soil samples as compared with mare basalts[20,21], these correlations strongly suggest that surface ejecta materials produced in large-scale meteoroid impacts are primary sources of the observed orbital magnetic anomalies. The lack of large-scale anomalies associated with major structural features such as the mascons argues against thermal remanence or chemical remanence acquisition by thick crustal layers cooling over long time periods in the presence of a large-scale steady magnetic field. The lack of clear evidence for thermal remanence acquisition for at least some fine-grained mare basalts[22] and the 0.025 G Thellier palaeointensity obtained for a young (<200 Myr) Apollo 17 impact-produced glass sample[23] are also problematical or contradictory observations for the core dynamo hypothesis.

Because many orbital anomalies are closely associated with relatively surficial impact-produced materials and since impacts are the dominant sources of localized, near-surface energy during lunar history, an impact-related origin for lunar magnetizing fields has been repeatedly proposed. The possibility that transient magnetic fields may be generated as a result of the interaction of highly electrically conducting ionized ejecta with a weak ambient interplanetary magnetic field was first suggested by Hide[24] with specific reference to lunar palaeomagnetism. Spontaneous generation of transient magnetic fields in energetic plasma clouds produced in hypervelocity meteoroid impacts was later suggested by Srnka[25] based on theoretical models for magnetic field observed in laser-heated plasmas. More recently, Cerroni and Martelli[26] have theoretically investigated field generation by thermally driven currents and compression of a pre-existing magnetic field at the boundary of an expanding ionized ejecta cloud with application to lunar palaeomagnetism. Field compression mechanisms involving cometary impacts have also been proposed on several occasions[17,27]. Although the kinetic energies of major impacts on planetary surfaces far exceed those achievable in laboratory experiments, some progress has been made towards experimental detection of plasma, magnetic field and rock magnetization effects associated with hypervelocity impacts onto basalt targets[28–30]. In this context, it is of interest that lunar palaeointensity data indicate that the more intense palaeofields (~1 G) were present near the termination of the basin-forming epoch[12]. Since impact-generated fields are expected to scale as a positive power of the scale of the impact and since the basin-forming impacts were the most energetic in lunar history, this result may support the impact model rather than refute it as was argued by Runcorn.

Thus, while it is not yet possible clearly to identify the mechanism(s) responsible for generation of strong magnetic fields at the lunar surface implied by the Apollo palaeomagnetic investigations, the possible importance of local mechanisms involving meteoroid impact processes is suggested by a large fraction of the available evidence. In such conditions, it is

advisable to consider cautiously the proposed implications of a former lunar dynamo.

RUNCORN REPLIES—Hood, Sonett and Srnka's conclusion that "the possible importance of local mechanisms involving meteoroid impact processes is suggested" largely rests (in their two penultimate paragraphs) on the observed correlation between the magnetic anomalies, mapped by the subsatellite magnetometers and by the reflected electron technique, and the ejecta blankets from impact events. This argument is scarcely logical: one might just as well argue that as lava flows are the most strongly magnetized rocks on the Earth and that as volcanoes are "the dominant sources of localized near surface energy during (Earth) history" the remanent magnetization of lavas must be produced by electric phenomena in the eruptions and has nothing to do with the geomagnetic field.

Hood *et al.* refer to two sources 100 km apart with "very different directions of magnetizations"; my Fig. 3*b* (ref. 1) shows that these (C1, C2) are roughly opposite. I explained that this is entirely consistent with the ejecta having a uniform direction of magnetization on an even larger scale. The ejecta, like the lavas, can only become magnetized with uniform direction after final emplacement in the presence of a uniform ambient field. No experimental demonstration has yet been made of magnetization produced during hypervelocity impacts on basalts that is attributable to transient plasma fields rather than the Earth's field, but such processes may well account for some magnetized material on the Moon, and elsewhere in the Solar System. My review was concerned with the test of the rival hypotheses. The bipolar clustering of north magnetic poles along three different axes, the proximity of the multi-ring basins to, and the parallelism of the velocities of the bodies that created them with the palaeoequators of corresponding age, strongly support magnetization by an ancient core dynamo field and cannot be understood on the magnetization by impact hypothesis. In Table 1 (ref. 1), the axis of rotation for the mean poles of Lower Nectarian age should be 50.4° S 162° E and for the Pre-Nectarian poles 7.8° N and 92.3 °E.

That the lavas in the maria basins, especially the thick ones in the circular maria (which account for the mascons), do not show up by the magnetic mapping is not a mystery as we have Apollo lava samples and their intensity of magnetization is 10^{-5} EMU cm^{-3}—an order of magnitude less than that of breccia. Such uniformly magnetized layers of lava produce less than 0.1 nT near their surfaces, except at their edges where the fields are about 10 nT but fall off so rapidly with height as to be undetectable by the subsatellite. By contrast, the magnetic effect of the Rima Sirsalis graben feature 10 km across and 300 km long has been detected[2,3]. That the intensity of magnetization of ejecta and breccia is an order of magnitude greater than that of lavas is explained by difference in the amount of free iron: it seems likely[4] that in the impacts reduction of silicates occurs due to rise in temperature with the release of Fe metal grains.

Since I wrote my review, two further lines of evidence for a lunar iron core have been found. First, lunar laser ranging has determined that the axis of rotation makes an angle of 0.23 arc s with the Cassini plane, the mean dissipation within the Moon corresponds to $Q = 28$. Seismic studies show that the Q of the outer parts of the Moon is 1,000, so Yoder[5] interprets the result in terms of an iron core. Second, Newsom and Drake[6] find that tungsten is depleted more in the lunar rocks than in the Earth's mantle, where it is 10^{-4} of Solar System abundances. As the latter depletion is ascribed to the Earth's core and as general abundance patterns between the Earth and Moon are similar, indicating a common origin, a further extraction of siderophile elements is required for the Moon: thus Newsom and Drake argue for an iron core. I wrote about the (now six) independent lines of evidence: "None of these is conclusive evidence for an iron core, in each case other models can be generated to fit the observations"; thus the free iron Drake and Newsom require might be distributed throughout the Moon like currants in a cake. That Hood *et al.* consider my account as "somewhat misleading" can only mean that they do not appreciate that even though each line of evidence is not conclusive the fact that all point to the existence of a lunar core lends much greater weight to the hypothesis than any one line could: a venerable principle of reasoning called Occams razor. In fact other models would be mutually inconsistent: the 'currants in the cake' model would not explain the low moment of inertia or the delayed seismic P wave.

Anderson's argument is based on Busse's theory in which the strength of a dynamo field is independent of the energy source driving the convection: experiments on dynamos and all other theories gave a contrary result[7]. Busse's result was obtained by equating the Coriolis term and the Lorentz force in the dynamo equation. I conclude that the dynamo theory, which in spite of its attractiveness did not in fact predict any of the many phenomena discovered in Earth and planetary magnetic fields, is not understood sufficiently well to be a secure basis for Anderson's argument.

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 500 words and the briefest of replies, to the effect that a point is taken, should be considered.

ANNOUNCING

NEW FOR 1984

Pharmaceutical Medicine

The contents will include:

★ **Original papers**
- on methods used to evaluate the efficacy and safety of drugs in man
- with emphasis on the validation of these methods
- covering human pharmacology, clinical research, drug epidemiology, and safety surveillance
- and especially the application of new methods to drug testing

★ **Abstracts of methodological studies published elsewhere**
- either used already in the context of drug investigation
- or methods suitable for drug evaluation

★ **Invited reviews on topics related to pharmaceutical medicine**

★ **Editorials and Commentaries**
- offering opinions
- high-lighting problems

★ **Correspondence, Book Reviews, and Calendar**

REPRODUCTIVE BIOLOGY OF INVERTEBRATES

Volume II: Spermatogenesis and Sperm Function

edited by **K.G. Adiyodi** and **R.G. Adiyodi,** *Vatsyayana Centre of Invertebrate Reproduction, Calicut University, Kerala, India*

This volume summarizes variations in sperm morphology and cytology, and also provides information on cytochemistry including enzymology of the respiratory metabolic pathways of sperm cells where such data are available. It examines aspects of motility, metabolism, behaviour, transport, storage and survival of spermatozoa, spermiation and spawning, sperm absorption, and the physiology of spermatozoa within the male and female reproductive tracts. Details and sequences of processes and the levels of complexity involved in spermatogenesis are described. Attempts have been made to identify the morphogenetic factors at work in the production of spermatozoa and to describe the endogenous and exogenous influences in spermatogenesis and sperm function. The taxonomic and phylogenetic implications of the structural relationships of spermatozoa are also discussed.

METHODS FOR NEURONAL RECORDING IN CONSCIOUS ANIMALS

by **R. Lemon,** *Department of Anatomy, Erasmus Universiteit, Rotterdam* and **A. Prochazka,** *St. Thomas's Hospital Medical School*

This book provides an up to date review of the current methodology for recording from single neurons in the central nervous system of conscious animals. This technique is now being widely used to explore the relationship between the activity of single neurons and behaviour, and has provided valuable insights into the function of the conscious brain.

IBRO Handbook Series: Methods in the Neurosciences, Volume 4

ADVANCES IN ANALYSIS OF BEHAVIOUR

Volume 3: Biological Factors in Learning

edited by **M.D. Zeiler,** *Department of Psychology, Emory University, Atlanta, USA* and **P. Harzem,** *Department of Psychology, Auburn University, Alabama, USA*

This volume deals with those biological factors that enter the learning situation. It brings together the recent thinking on the topic by major researchers in the area. It will be of value therefore to advanced students and researchers whether their interest in learning stems from psychology or other biological sciences of behaviour.

Wiley Series on Advances in Analysis of Behaviour

November 1983 — 420 pages
0471 90137 7 — $75.00/£39.00

DORSAL VENTRICULAR RIDGE

A Treatise on Forebrain Organization in Reptiles and Birds

by **P.S. Ulinski,** *The University of Chicago*

This book provides the first critical review and synthesis of ongoing research on the structure and function of the dorsal ventricular ridge (DVR), a characteristic brain component of birds and reptiles. It outlines the major features of the DVR and explains its role in reptilian and avian sensory processes and behavior.

Wiley Series in Neurobiology

November 1983 — 300 pages
0471 87612 7 — $51.95/£36.95

THE CHEMISTRY OF PEROXIDES

edited by **S. Patai,** *Department of Organic Chemistry, The Hebrew University, Jerusalem, Israel*

The series 'The Chemistry of Functional Groups' is planned to cover in each volume all aspects of the chemistry of compounds containing one of the important functional groups in organic chemistry.
This volume contains material on functional groups which include the -O-O- bond, i.e., organic peroxides, hydroperoxides, acyl peroxides, peroxy acids and esters and ozonides. None of these groups have been treated in the volumes which appeared up to now in the series.

Series: The Chemistry of Functional Groups

December 1983 — 1020 pages
0471 10218 0 — $225.00/£120.00

SOLID PHASE BIOCHEMISTRY

Analytical and Synthetic Aspects

edited by **W.H. Scouten,** *Bucknell University*

A comprehensive introduction to all major applications of solid phase biochemistry, including affinity chromatography, immobilized enzymes, solid phase synthesis of proteins and nucleic acids. It discusses matrices used in affinity chromatography and other analytical processes based on solid phase systems. The book covers genetic engineering, borate chromatography and experts review significant achievements in the field and discuss the most useful techniques.

Chemical Analysis: Volume 66

Turing and the computer

I.J. Good

Alan Turing: The Enigma. By Andrew Hodges.
Burnett Books (distributed by Hutchinson)/Simon & Schuster: 1983. Pp.587. £18, $21.75.

A SHORT biography of Alan Turing was written by his mother but this new one, by Andrew Hodges, is much more complete, objective and illuminating. Turing was one of the pioneers of computer science. His most notable work in this area was related to the foundations of mathematics, appreciation of which requires some relevant background.

A set whose elements can be put into one-to-one correspondence with the positive integers 1, 2, 3, . . . is said to be *countable*. For example, the even numbers 2, 4, 6, . . . form a countable set. The mathematician David Hilbert invented a hotel in which the rooms were numbered 1, 2, 3, . . . to infinity. One day all the rooms were occupied, but a countable number of additional people wanted rooms. So, for each n, the resident in room n moved to room $2n$, thus vacating the odd-numbered rooms for accommodating the newcomers.

A number of the form m/n, where m and n are integers, is said to be *rational*. At first sight, the set of rational numbers seems to be "larger" than the set of integers, but it is still countable. For we can imagine the positive rational numbers "counted" in the order 1/1; 2/1; 1/2; 3/1, 2/2, 1/3; 4/1, 3/2, 2/3, 1/4; 5/1, ... This order fills successively larger triangles if m/n is written at a point with coordinates (m, n). Every positive rational number will ultimately get counted, in fact repeatedly. We might now wonder whether *every* set is countable, but Georg Cantor showed, in about 1880, that the set of "real" numbers is not countable. A real number can be written as an infinite decimal; for example, $\pi = 3.1415926\ldots$ is a real number. We now show that the real numbers between 0 and 1 are uncountable by assuming that they *are* countable and then deducing a contradiction.

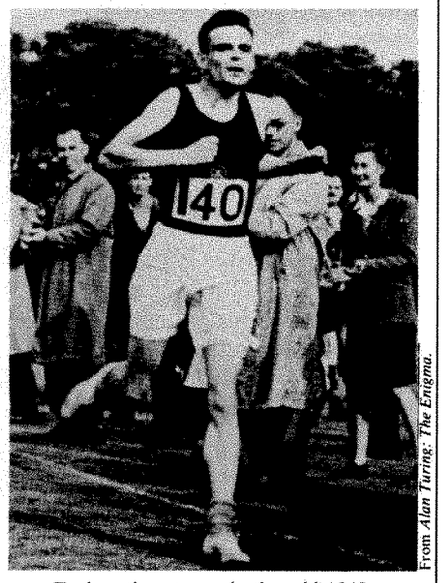
Imagine a sheet of squared paper having a top left-hand corner and extending infinitely to the right and downwards. Suppose the real decimals between 0 and 1 can be listed in the order $x_1, x_2, x_3, \ldots$. (We are not assuming, for example, that $x_1 < x_2 < x_3 < \ldots$ or that $x_1 > x_2 > \ldots$.) Let the digits of x_1 be written on the first row of the squared paper, the digits of x_2 on the second row, and so on. Now define a new decimal y whose nth digit (for each n) is not the same as the nth digit of x_n. Clearly y is not equal to x_n for any n. So there is a real number y not on the list and this contradicts our assumption that all the real numbers were on the list. Thus the real numbers are uncountable. (I have ignored the unimportant ambiguous notation for terminating decimals such as .19999 . . . .) This argument is called Cantor's *diagonal argument* and it shows that infinite sets are not all of the same "size". Some great mathematicians at the time called Cantor's work theology because they were unwilling to admit he was a genius.

The diagonal argument has since been used, in a very much more sophisticated manner, to prove remarkable results in the logic of mathematics. The first example was published by Kurt Gödel in 1931. He showed that no finite set of axioms about the integers could capture all their properties. In other words, given a finite set of axioms, and a precisely specified definition of what is meant by a proof, there are statements in the theory of numbers that are true but cannot be proved.

Courtesy Hutchinson.

Alan Turing, at the time of his election to the Fellowship of the Royal Society in 1951.

One might naively assume that the *meaning* of the truth of a mathematical statement is that it follows from the axioms. But this assumption can be seen to be dubious by means of the following simple example. Consider the conjecture that π contains arbitrarily long runs of 7s in its decimal expansion. For the sake of argument, suppose that this conjecture is true. Then, for each positive integer n, one could in principle prove that the decimal expansion contains runs of n consecutive 7s by straightforward computation. (When a mathematician says that something can be done "in principle" he usually knows that it is impracticable.) But it might not be possible to prove the conjecture itself because a proof must, by definition, be of finite length.



We are now ready to understand broadly what Turing discovered in 1935 when he was only 22. He first defined rigorously a "paper machine" capable of carrying out any conceivable calculation when suitably programmed, a concept now called a "Turing machine" by computer scientists. General-purpose electronic computers are approximately equivalent to Turing machines. He then defined a computable (real) number x as one for which a program (of finite length) could be written that would compute more and more digits of x. Since the number of possible programs is only countably infinite, and only some of them give computable numbers as output, it follows that the number of computable numbers is also only countably infinite. But Turing showed that there is no *explicit* way to do the counting. For suppose it is possible for a master program to have as its output a list of all the computable numbers, on squared paper, x_1 in row 1, x_2 in row 2, etc. Of course the computer would not list the whole of x_1 before starting on x_2, etc. It might, for example, print in order $x_{11}, x_{21}, x_{12}, x_{31}, x_{22}, x_{13}$, etc., where x_{ij} is the jth digit of the computable number x_i. (Compare the triangular process for "counting" the rational numbers.) But then one could define a *new* computable number by means of the diagonal process. So the alleged master program is not really a master program at all — and this completes the proof of Turing's result by *reductio ad absurdum*. From this result he was able to deduce that there is no automatic procedure, using only the rules of a given formal system, that can decide, for every mathematical statement, whether it is provable, unprovable or neither. In the book, Andrew Hodges provides a rigorous account of this work.

During the Second World War Turing worked on the cryptanalysis of the Enigma, a German cryptographic machine. He had an important idea for improving the "Bombe", which was the main cryptanalytic machine used for attacking the Enigma. The idea was based on the logical fact that from a contradiction anything can be proved, a fact that Wittgenstein thought was unimportant. It saved a vital factor of about 26 in the running time, and if it had not been for that the Allies might have lost the war. Turing also made important statistical contributions, but had little to do with the Colossus, a cryptanalytic machine which, unlike the Bombe, had much in common with later electronic computers.

Immediately after the War Turing worked on the design of the ACE (Automatic Computing Enigma) at the National Physical Laboratory (NPL), a post he took partly because he did not enjoy lecturing. The storage of the ACE was based on mercury delay lines; and its programming, as M.H.A. Newman said, was like catching mice just as they were entering a hole in the wall. Some machines with magnetic drums had the same disadvantage. Turing was not happy at NPL,

because he was not allowed to be both a mathematician and an engineer, and in 1947 he took a year's leave during which he wrote an influential philosophical paper on artificial intelligence. In this article he disposed of most of the arguments that are made against the possibility of the machine simulation of thought processes. In 1948 he moved to Manchester and produced the programming system for the Manchester University Computer, Mark II.

Turing was logical but emotional, excitable but kind, eccentric but natural, and intellectually and physically strong. He was a very good long-distance runner and

From *Alan Turing: The Enigma.*

Turing, the runner, in the mid-1940s.

might have run in the Olympic games, but developed a neurological complaint in a leg. After the war he admitted privately that he ran partly to work off libido and that he was a homosexual; fortunately MI5 did not know of his homosexuality during the war. In 1952 he published a seminal contribution to the mathematical theory of growth, but in the same year he was convicted for having a homosexual relationship with a 19-year-old man and was put on probation and on chemical therapy. In June 1954 Turing committed suicide.

In this biography Hodges treats most of these aspects of Turing's life, and many others, and attempts to trace the origins of his ideas in his early environment. The book is researched and written extraordinarily well; I found only a few minor inaccuracies in spite of having known over a hundred of the people mentioned by Hodges. It is a first-class contribution to history and an exemplary work of biography. □

I.J. Good is University Distinguished Professor of Statistics at the Virginia Polytechnic Institute and State University, Blacksburg, Virginia. A collection of his writings, Good Thinking: The Foundations of Probability and Its Applications, *was published last year by the University of Minnesota Press. During the Second World War, he was Turing's and later M.H.A. Newman's main statistical assistant in cryptanalytic work.*

Formats for language development

John McShane

Child's Talk: Learning to Use Language.
By Jerome Bruner.
W.W. Norton/Oxford University Press: 1983. Pp.144. Hbk $13.95, £11; pbk £5.95.

A CHILD must master a complex grammatical system in acquiring language. How he does so has been a central issue of debate and research for the past twenty-five years. Much of the discussion has concerned what sort of unique language-learning capacities human beings might or might not have. However that question is answered eventually, a child would not learn a language without being part of a community of other speakers.

Thus, any reasonably complete answer to the question of language acquisition must give an account of both the child's language-learning capacities and the environmental features that stimulate those capacities. Bruner's book is a summary of a decade of his work on the role of the environment in language acquisition. It is not a general review of research in this area; indeed, there is little mention of some standard issues such as the grammatical characteristics of parental talk to children. Instead, problems that have concerned Bruner during the past decade are examined, considered and summarized. The book provides a clear and illuminating introduction to these concerns but, inevitably perhaps, fails to satisfy one's desire for a thorough-going consideration of the positions of other theorists.

Chapter 2, which deals with the relations between language and non-language, is the clearest example of where more was needed. Bruner makes two points concerning the non-linguistic foundations of language. The first is that language structures have analogues in other areas of cognition. Thus, at least some of the structure of language might be derived non-uniquely. The trouble with this view is that it is notoriously difficult to move from pointing at plausible candidates from which to derive grammatical structures to demonstrating a causal link, as Bruner recognizes. Because he has not set out to write a detailed critical review, these complex issues are finessed. Bruner's other point is that a child is not simply learning grammatical structures in learning a language; he is also learning the conventions for the use of linguistic structures. He argues forcefully that many of these conventions are set-up by the child's social environment, independently of the child's grammatical abilities and usually well in advance of them. The mechanism by which this occurs is the heart of the book.

Bruner argues that adults create structured interactions with children and maintain the basic structure over many months while gradually handing over more and more control of the structure of the interaction to the child. Bruner calls these structures *formats*. Within a format a child gradually achieves an increasing degree of competence with the adult's aid and cajoling. As competence increases so the adult demands for competence increase. Formats for peekaboo games, reference and requesting are considered in some detail.

Not many researchers have followed Bruner's path of exploring the *interaction* of adult and child in detail and implicating the structure of the interaction in a causal model of development. To my mind this is a great pity. While this particular tack does not answer all questions about language development, it seems to be a more fruitful approach to the role of the environment than the more common technique of correlating features of parental speech with later features of the child's speech, in complete oblivion of the interactional context in which the speech occurred. The more dynamic approach of Bruner is both time-consuming and labour-intensive on the part of the researcher. This book makes a sound case for the investment required. □

Control by calcium

P.F. Baker

Intracellular Calcium: Its Universal Role as Regulator.
By Anthony K. Campbell.
Wiley: 1983. Pp.556. £36.75, $79.95.

THE importance of intracellular calcium as a widespread, if not universal, regulator of cell function is well recognized. "Control by calcium" exhibits three key features: maintenance of a very low cytosolic free Ca in the face of intracellular and extracellular pools of Ca at much higher concentrations; the presence of special voltage or receptor-controlled mechanisms for permitting Ca to enter the cytosol from one or more of these high Ca pools; and the existence within the cytosol of a special class of Ca-receptor proteins that serve to transduce alterations in free Ca to changes in enzyme activity and cell function. Despite this apparent simplicity, it is often difficult in practice to unravel the part played by calcium in a particular physiological process and much effort has been expended in trying to develop suitable experimental techniques. The success of this effort is

now reflected in an avalanche of publications in the primary literature.

When new material is appearing at such an alarming rate, to embark on a book can be a dangerous decision. Exceptions are books that aim to impose some sort of order on the apparent chaos of the primary literature and those that advance a novel framework within which the new discoveries can be set. Tony Campbell's *Intracellular Calcium* falls squarely into the first category.

After discussing the "Natural History of Calcium" and "Calcium Methodology", Campbell sets out to draw together the arguments for and against a role for Ca in a host of cellular processes with chapters on "Intracellular Ca and the Electrical Activity of Cells", "Calcium and Cell Movement", "Intracellular Ca and Intermediary Metabolism", "Endocytosis and Exocytosis", "The Reproduction and Development of Cells" and "The Pathology and Pharmacology of Intracellular Ca". Each of these often contains long accounts of basic cell biology as an essential introduction to discussion of the possible roles of calcium. Unfortunately, except where that role is already well known, these chapters often end rather inconclusively. They nevertheless certainly highlight many unsolved problems of cell biology in which calcium may well be involved.

Such a wide sweep has, however, posed obvious difficulties for the author and despite 556 pages the book falls somewhere between being a natural history of intracellular calcium and a critical discussion of those processes where involvement of calcium is still controversial. In consequence some important growth areas of real significance to "control by calcium" are under-represented and presented in a relatively uncritical fashion. Two obvious examples are phosphoinositol metabolism and the transport of calcium across membranes; but I suspect that most specialists will find fault with the presentation of their own particular neck of the calcium wood. It is a pity that the author did not seek more feedback before publication. In this way the most glaring errors might have been avoided and the author might also have been encouraged to reference all the most important observations with original papers. As it is, the policy is mixed: sometimes original papers are quoted, in other places reviews, but all too often interesting observations go incognito.

It is all too easy to find fault. This is a very personal account of the many roles of intracellular calcium that will be an obvious starting point for those entering the field. It will also, I feel sure, infect both the old hand and the new with some of Tony Campbell's great enthusiasm for his subject. □

P.F. Baker is Halliburton Professor of Physiology at King's College, University of London.

Look back to viral oncology

Robin Weiss

Oncogenic Viruses, 3rd Edn.
By Ludwik Gross.
Pergamon: 1983. Two volumes, pp.1,203. £100, $200.

LUDWIK Gross has influenced the development of experimental oncology in the post-War period through three distinct contributions. First, after many years of frustrating experimental work, in 1951 he showed that the thymic lymphoma of AKR mice could be transmitted to new-born C3H mice by cell-free filtrates; this discovery of murine leukaemia virus, following Bittner's demonstration of the milk factor causing mammary carcinoma in mice 15 years earlier, firmly established that viruses cause cancer in mice, and led to a resurgence of tumour virus research. Second, in 1953, Gross reported that salivary gland tumours (also induced by the thymoma extracts) were caused by a distinct agent, later named polyoma virus by Sarah Stewart, who independently discovered the virus in the same year. Finally, in 1961, Gross published the first book wholly devoted to tumour viruses.

Twenty years ago Gross's *Oncogenic Viruses* was the only comprehensive general text available. As such, the book was invaluable. A second enlarged edition was published in 1970 which included much new material, though it omitted discussion of some of the most interesting *in vitro* experimentation on oncogenic viruses and cell transformation established during the 1960s. Now Gross has produced a third edition, expanded to two volumes, and including some new chapters on oncogenic viruses of fish, "slow virus diseases" and iatrogenic transmission of human cancer.

I looked forward to reading this new edition in the hope of seeing the recent strides made in experimental oncology placed in perspective by the man who discovered two of the most intensively studied tumour viruses. I was deeply disappointed. Whilst Gross writes in his introduction that "all chapters . . . have been brought up-to-date in order to include the most important observations which have become available since the previous edition was prepared", this is a travesty of what follows. For instance, there is not a single citation of David Baltimore's work, either on reverse transcriptase (which is never mentioned), or on Abelson leukaemia virus (this important virus and its associated neoplasms are dismissed in a single paragraph).

Gross excludes any discussion of viral replication and genetics. This could be explained by his remark that "molecular biology is not discussed in this book". But while the author wisely did not aim to write a detailed molecular treatise, no modern text can afford to ignore the *results* of molecular biology in changing our conception of tumour virus biology, and indeed of cancer as a whole. It is difficult to see how any author can claim to present insights into viral oncogenesis without at least a nodding reference to "early" functions of papovaviruses or to retrovirus oncogenes.

By eschewing all data on viral and host genetics, whether obtained by classical or molecular methods, much of value in the detailed descriptions of early virus isolates is diminished. Such important topics as viral transmission, defectiveness, and host permissiveness and resistance are discussed in terms of concepts that were already outdated at the time of the second edition 13 years ago. For example Gross himself coined the terms "vertical" and "horizontal" transmission for tumour viruses in 1944, and the existence of hereditary infections is described at length in many chapters. Yet the crucial distinction between congenital infection and the Mendelian inheritance of integrated proviruses is not made until the final chapter, almost as a footnote. Classical papers, such as those by Payne and Chubb (*J. Gen. Virol.* **3**, 379; 1968) on the Mendelian inheritance of viral antigens in chickens and Bentvelzen and Daams (*J. Natl Cancer Inst.* **43**, 1025; 1969) on the chromosomal transmission of mammary tumour virus genomes in GR mice are not cited, let alone the wide body of knowledge on endogenous viral elements accrued in the 1970s which clarified the whole subject of retrovirus latency and activation. Gross devotes five chapters to murine leukaemogenesis without once mentioning xenotropic or recombinant viruses.

The considerable progress in the study of human oncogenic viruses since the last edition receives erratic treatment. With the burgeoning interest in human papilloma viruses and the isolation of new strains associated with particular neoplasms, it is astonishing to find the most recent reference dates from 1965. Hepatitis B viruses of humans and animals are summarized in one-and-a-half pages, and human T-cell leukaemia virus in one page plus an electron micrograph. There is, however, a whole chapter on Epstein–Barr virus, and a useful new chapter on "Inadvertent and Experimental Transmission of Human Cancer".

As an historical survey of viral oncology up to 1965, *Oncogenic Viruses* is unparalleled. But no reader or librarian should suppose that this new edition gives a contemporary account of viral oncology. As with Darwin's *Origin of Species*, I shall treasure the earlier editions, and regret that Gross has devoted much effort on a third edition which should not have been published. □

Robin Weiss is Director of the Institute of Cancer Research, London.

The foraminifera in time

Gerta Keller

Neogene Planktonic Foraminifera: A Phylogenetic Atlas.
By James P. Kennett and M.S. Srinivasan.
Hutchinson Ross: 1983. Pp.265. $36.50, £35.40.

A COMPREHENSIVE manual for the identification of Neogene planktonic foraminifera has been needed for some time. With this publication, James P. Kennett and M.S. Srinivasan have gone a long way to satisfying the need. The book contains high-quality scanning electron micrographs of 150 species which show the characteristic morphologies of type species as well as differences in surface ultrastructure. Each illustration is accompanied by a concise description of the species, and a note of its stratigraphic range and locality; a phylogeny based on morphological features is proposed for each lineage.

The book is especially noteworthy for the authors' representation of planktonic foraminifera by phylogenetic groups and for their erection of several new subgenera to distinguish evolutionary taxonomic lineages. This approach is both novel and useful for students, but unfortunately the subject is treated in a rather cursory manner. Apart from general comments in the introductory chapter there is little discussion of the proposed lineages and ancestor–descendant relationships, or of their controversial nature: ancestor–descendant relationships for many species are *not* well understood and, as noted by the authors, at present the use of phylogenetically defined subgenera is limited to themselves and one other worker.

There are a few minor, but important omissions of data on diachroneity of species ranges in the taxonomic descriptions. Species ranges (first and last appearances) are critical for the chronostratigraphic interpretation of sedimentary sequences. Therefore, care should be taken to note maximum species ranges (usually in the tropics) as well as known diachronous ranges of many species between tropical and temperate regions. The authors sometimes fail in this respect. For instance, *Globorotalia plesiotumida* (which defines the base of Zone N17) is diachronous even between the east and west equatorial Pacific, appearing at 9 Myr in the west and at 8 Myr in the east. For this reason, the first appearances of *Globigerinoides conglobatus* and *G. obliquus extremus* are more reliable in defining the base of Zone N17. Similarly, *Globoquadrina dehiscens* disappears in the tropics at 5 Myr, but at 10 Myr in temperate regions.

Some other species' ranges listed are also anomalous. For example, *Globorotalia birnagae* and *Globigerinoides bolli* are listed as first appearing in Zones N7 and N12 respectively. However, both species have been reported from the early Miocene Zone N4. *Globigerinoides bulloideus* which is reported as first appearing in the late Miocene Zone N17 actually evolves in the middle Miocene. Most of these differences probably stem from the fact that the authors' synthesis is based primarily on investigations of deep-sea sequences from the south-west Pacific which, contrary to their claim, are not representative of the world oceans. Students should be aware of such problems and consult recent reports of the Deep Sea Drilling Project and micropalaeontological journals as appropriate.

While I have dwelt on the shortcomings, *Neogene Planktonic Foraminifera* is a well-conceived book for which the authors are to be thanked. It is an extremely handy manual for species identification and biostratigraphic interpretation which will prove invaluable to research workers, and to teachers and their students. □

Gerta Keller is in the Branch of Paleontology and Stratigraphy of the US Geological Survey, Menlo Park, California.

In the beginning

A.G. Cairns-Smith

Earth's Earliest Biosphere: Its Origin and Evolution.
Edited by J. William Schopf.
Princeton University Press: 1983. Pp.543. Hbk $95, £88; pbk $42.50, £40.

THE Precambrian Paleobiology Research Group was a realized pipe dream of J.W. Schopf's. It consisted of 24 scientists of appropriately diverse callings brought together to work, at UCLA and elsewhere, between May 1979 and August 1980. They engaged in research, in the field and in the laboratory; they met frequently, they talked and they published more than a dozen papers. And now, as the main product of their efforts, there is this splendid book.

The book includes the practical results of the group's activities, but it is not merely a series of research papers — rather, it is more an advanced textbook. The chapters are mainly reviews, but in spite of there being 21 contributors are reasonably well integrated. This was all helped no doubt by the editor's active authorship in almost half of them.

Preston Cloud was invited to introduce the book with a perspective on what he calls the new paradigm of biogeologic history — a mid-twentieth-century move from a too devout Uniformitarianism. The Earth is seen as having been substantially different in its early days, with a change through its history from reducing to oxidizing conditions — a somewhat spasmodic change, though, with atmosphere, hydrosphere, biosphere and lithosphere evolving in concert.

A radical version of this new paradigm starts with the Oparin–Urey highly reducing atmosphere for the early Earth, a CH_4–NH_3–H_2O type. Under such an atmosphere the probiotic synthesis of organic molecules should have taken place easily. Sherwood Chang *et al.* discuss in detail the question of the character of the probiotic atmosphere, believing that a build-up of organic molecules on the primitive Earth was a necessary preliminary to the start of a biological evolution. The strongly reducing first atmosphere is now seen as only one possibility — and perhaps not the most likely. The difficulty in deciding this question comes from trying to determine sequences of events during the formation of the Earth itself, some 4.5 Gyr ago. It is now generally thought that the early atmosphere was derived mainly from outgassing of the Earth. The nature of this atmosphere would then have depended on how much metallic iron there had been near the surface of the Earth, and *that* would have depended on how and when the core of the Earth was formed. These matters are also discussed in a chapter by David J. Stevenson, and they form the starting point for a discussion of the evolution of the lithosphere by W. Gary Ernst. The core formed early on, it seems, and most of the outgassing was early as well.

So after a somewhat catastrophic start there is, after all, a more Uniformitarian picture of the early Earth, according to several of the authors here — but with some gradual changes superimposed, needless to say. James C.G. Walker *et al.* take such a view. By the time there was a stable surface — and certainly by 3.8 Gyr ago when the most ancient known sediments were formed — the Earth was not so vastly different a place from now. By that time, it seems, the atmosphere was basically CO_2–N_2–H_2O (whether or not it had ever been anything else) and evidently weathering and sedimentation processes were already in action. Walker and his colleagues make a plausible case for there having been much more carbon dioxide though — perhaps 100 times as much as now — and there is ample evidence for low or negligible oxygen levels.

Most people think that the appearance of significant amounts of oxygen in the atmosphere (very roughly 2 Gyr ago) was due to increasing photosynthetic activity by organisms. Jan Veizer suggests that organisms had perhaps been producing oxygen in quantity long beforehand and it was the gradual evolution of the lithosphere that brought about this atmospheric change: the Earth was cooling; reducing power derived from the mantle (e.g. Fe^{2+}) was being less vigorously injected into ocean waters and could no longer keep pace with the photosynthetic oxygen pro-

duction. . . . A neat inversion, this, of the more usual idea that evolutionary biology is the gradualist science and geological history the Uniformitarian one. Indeed ^{13}C studies on ancient sediments, reviewed by Shidlowski *et al.*, fit perfectly well with the notion that a biosphere of similar scale to today was already present 3.5, possibly 3.8 Gyr ago: there is a typical biological (autotrophic) signature in the isotope ratios of reduced and oxidized materials, although it must be said that such signatures can be forged by non-biological processes.

Chapters by Schopf, Malcolm R. Walter and Hans J. Hoffmann on Precambrian fossils serve to underline the stability of many biological forms. Not all that much seems to have been happening between 3.5 Gyr ago and towards the end of the Precambrian (0.57 Gyr ago) when truly multicellular forms of life came on the scene. The 3.5 Gyr date is of rocks from Western Australia that contain fossil stromatolites (microbial colonies) as well as fossils of filamentous bacteria similar to modern members of stromatolite communities. To be told that of 43 cases of pre-2.5-Gyr-old sets of "microfossil-like objects" there are only two that are well proven, is a little worrying — one wonders whether more work might cast doubt here too. Well, there is no absolute security in this field and the evidence seems pretty good to me. If it holds it is the nearest we have yet got to the origin of life (although still not very near if these are fossils of anything at all like modern prokaryotes).

Past sequences of events within the biosphere can perhaps be inferred from the ways in which present biochemical subsystems depend on each other. Howard Gest and Schopf see sugars as primary materials, with fermentation and then (non-oxygenic) photosynthesis having been achieved early on (by 3.5 Gyr ago on the basis of isotope and fossil evidence). J.M. Hayes makes a case for oxygen-producing photosynthesis having appeared by about 2.8 Gyr ago: a wide spread of carbon isotope ratios in reduced materials of that sort of age fits with the idea that around then both oxygen-rich and oxygen-poor sedimentary basins were common. Whatever the exact timing, the more general oxygenation of the environment is seen by David J. Chapman and Schopf to have left its mark in the structures of modern biochemical pathways which indicate a progression from our remoter ancestors, which could not put up with oxygen, through forms that could tolerate it, to those that needed oxygen to survive.

This is a good-looking book with plenty of data and models attractively presented in pictures, diagrams and tables. I can see it in studies, in laboratories and even on coffee tables. It should help to generate some new addicts for an untidy, unsafe but exciting field. □

A.G. Cairns-Smith is Reader in Chemistry at the University of Glasgow.

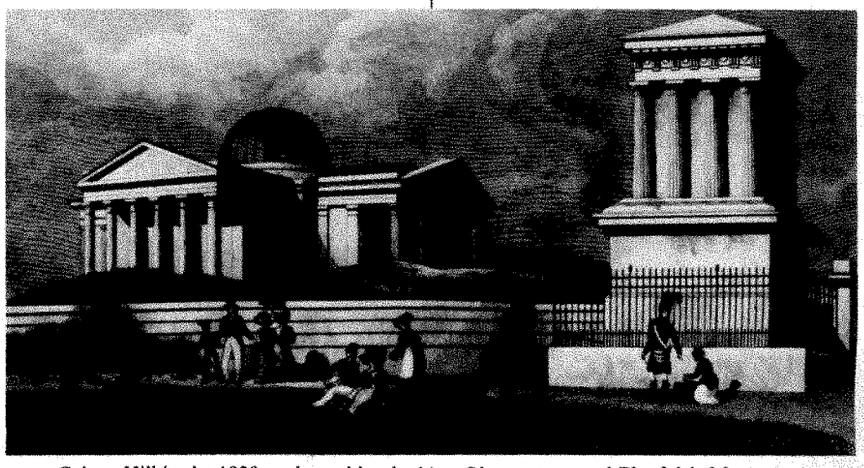
Astronomical city

David W. Hughes

The Story of Astronomy in Edinburgh.
By Hermann A. Brück.
Edinburgh University Press: 1983.
Pp.151. £8.50.

EDINBURGH is the home of a famous university and a Royal Observatory, and the history of astronomy in that city is a tale of the intricate symbiotic relationship between the two establishments. Both are old. Nineteen-eighty-three saw the 400th anniversary of the University and 1972 the 150th anniversary of the Royal Observatory, so it is a fitting time to delve into the development of astronomy in the city. Between the years of 1957 and 1975 Hermann A. Brück held "by far the most attractive astronomical post in the United Kingdom", that of being jointly Astronomer Royal for Scotland and Regius Professor of Astronomy at the University of Edinburgh. He has written a delightful book which will appeal to a wide variety of readers.

The story divides easily into three parts, the first centring around Calton Hill for which William Playfair designed an observatory modelled on the Greek Temple of the Winds. This replaced the Old Observatory on the same hill, which had been used by the Astronomical Institution of Edinburgh, a society founded in 1811, and the first British society whose activities were entirely devoted to the pursuit of astronomy. Their aim was to establish an observatory which could be used both for scientific research and for popular observation. In 1785 Robert Blair was appointed as the first professor of astronomy and this was followed in 1822 by King George IV being "graciously pleased to permit the Observatory on Calton Hill to be styled The Royal Observatory". In 1834 the Astronomical Institution transferred the use of the Observatory to the University on the condition that the Government of the day appointed an Observer who would be titled Astronomer Royal for Scotland and would also occupy the Chair of Astronomy at the University of Edinburgh. Thomas Henderson was appointed and was followed by Charles Piazzi Smyth who dominated Edinburgh astronomy between 1846 and 1888.



Smyth was one of the most fascinating personalities in the scientific world during the Victorian era. He founded "mountain astronomy", realizing that height improved the effectiveness and precision of astronomical observations, immersed himself in pyramidology and ignored his university duties as there were "generally no students at all for so untoward, despised and poverty-stricken a subject in Scotland".

Things obviously had to change and Ralph Copeland, Smyth's successor, witnessed the building of a new observatory at Blackford Hill to the south of Edinburgh and the transfer to that observatory of the Dunecht instruments which previously belonged to the 26th Earl of Crawford. Spectroscopic astrophysics flourished and under the successive leadership of Frank Dyson, Ralph Sampson and W.M.H. Greaves the observatory developed spectrophotometry and high-precision photographic photometry.

In 1957 Hermann Brück took over and in his 18 years supervised a great expansion of the observatory, the numbers of staff growing from less than ten on his arrival to well over a hundred on his retirement. Research in Edinburgh led to the development of autoguider systems, photoelectric exposure control for spectroscopes, ultraviolet observatories in space, satellite tracking and the GALAXY and COSMOS machines which can automatically scan photographic plates and measure the positions and brightness of stars and galaxies.

Brück writes that his "years on Blackford Hill have been extremely happy ones", a happiness which echoes through his story. There can be few better advertisements for astronomy, or for Edinburgh as a place to pursue the subject. □

David W. Hughes is a Lecturer in Physics and Astronomy at the University of Sheffield.

Teleki to Leakey

Andrew Hill

Koobi Fora: Researches into Geology, Palaeontology, and Human Origins. Volume 2 The Fossil Ungulates: Proboscidea, Perissodactyla, and Suidae.
Edited by J.M. Harris.
Oxford University Press: 1983. Pp.320. £45, $95.

IT WAS less than a hundred years ago that Europeans first looked upon Lake Turkana, when Count Samuel Teleki von Szek and his fellow traveller Ludwig von Hohnel came across it on 6 March 1888. "An entirely new world was spread before our astonished eyes", wrote von Hohnel on seeing the huge expanse of water in the deserts of northern Kenya.

After Teleki few Westerners visited the lake. Sir Vivian Fuchs led an expedition there in the 1930s, and in 1943 Louis Leakey was told of the existence of fossils by a District Commissioner, but was denied access at that time. It was left to his son Richard to rediscover the palaeontological potential of the area in 1967. He began the Koobi Fora Research Project in 1968 and it still continues. While it may be hyperbolic to suggest an entirely new world has been spread before our astonished eyes as a result, certainly the research of the Project has changed our view of palaeoanthropology in significant ways.

In 1968 only three specimens of early hominid were known from Kenya. The Koobi Fora expedition has changed that, for a great deal of material has come from Lake Turkana, most of it discovered by an expert group of Kenyan fossil prospectors led by Kamoya Kimeu. Now the list of hominid fossils exceeds 150 for Koobi Fora alone, and the project has spawned as many publications. This monograph, edited and largely written by John Harris, is the most recent of them. It is dedicated to the memory of the late Sonia Cole, the technical editor of this and the first Koobi Fora volume, who in many ways made notable contributions to palaeoanthropology in Africa.

Aside from the sheer abundance of hominid specimens, what are the main achievements of the Project? Koobi Fora is one of three large sites in eastern Africa that document the radiation of hominids between two and one million years ago. Olduvai in Tanzania provided the first evidence, an assortment of specimens comprising two new taxa, *Australopithecus boisei* and the originally more controversial *Homo habilis*. It also produced the earliest complete assemblages of lithic culture. Work near the Omo River in southern Ethiopia resulted in important collections of vertebrate fossils, and a series of volcanic tuffs through the succession made it possible to establish a reliable temporal framework by potassium–argon dating. Although numerically abundant, the hominid finds were not spectacular, as sedimentary conditions in that area favoured mainly the preservation of isolated teeth.

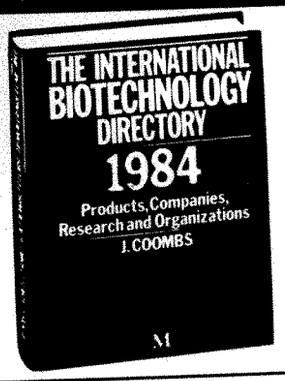
Koobi Fora provided more complete specimens. Amongst them are good examples of *Australopithecus boisei*, enabling us to appreciate the high degree of sexual dimorphism and range of variation in this interesting creature. There are specimens that appear to confirm the reality of *Homo habilis*, and yet others that probably represent a third species. This might explain some of the earlier interpretative problems within the Olduvai sample. Another step was the recognition at Koobi Fora of the great antiquity in Africa of *Homo erectus*. This is the species generally thought to be immediately ancestral to our own, and is also the first hominid found outside Africa. Most specimens from the Far East and Europe, though, are more recent than one million years, whereas some from Koobi Fora are half-a-million years older. This makes it possible that even *Homo erectus* originated in Africa rather than elsewhere.

A theory being pushed with some vigour until a few years ago was that once hominids and material culture were established there was room ecologically for only one species. The finding of *Homo erectus* at this level, where it was contemporary with at least *Australopithecus boisei*, successfully demolished that notion. Hominid post-cranial bones were also found, resulting in a better understanding of locomotion in these early groups.

A variety of other research has been conducted under the auspices of the expedition. Some of this is general and basic, for example that on evolutionary theory using the excellent record of fossil freshwater gastropods. Other work, such as the investigations of the geology, palaeoecology and taphonomy of recent and fossil bone assemblages, is essential to understanding the environmental and time context of the hominids. Some deals fairly directly with hominid activities. Glynn Isaac, who with Richard Leakey is the Project's co-director and co-editor of this Koobi Fora monograph series, has led a team of archaeologists which has described two successive patterns of early stone tool technology that comprise distinctive facies within the Oldowan Industrial Complex. The team has also done much valuable work on principles of site interpretation.

Although the stone tools and the bits and pieces of old human skeletons form the glamorous treasures of palaeoanthropology, over 6,000 fossils of a wide range of other vertebrates have also been collected. These span the period from four to one million years ago, and are intrinsically important for what they tell us about the origins and evolution of certain taxonomic groups world wide, and also for their contribution to understanding the environments and ecology in which the hominids evolved. John Harris is the coordinator of palaeontology in the Project, and the present volume is the first of two dealing with the fossil ungulates. It is not designed for casual reading. Five of the seven chapters are detailed taxonomic treatments of the Deinotheriidae, Elephantidae (by Michel Beden), Rhinocerotidae, Equidae (by Vera Eisenmann), and Suidae, with complete listings and field locations of specimens. An introductory chapter gives the history of exploration and stratigraphical interpretation; a concluding one discusses correlation with other sites, biozonation and environmental change.

Correlation is one of the crucial questions to which the palaeontological information relates. The initial radiometric dating at Koobi Fora led to the impression that the artefacts there, and the fossil material belonging to the genus *Homo*, were the oldest in the world. Palaeoanthropologists traditionally have a proprietary attitude to their finds, and if they can possess the oldest they are in a very attractive position. It is attractive for publicity and therefore funding if nothing else, and so is a position they are understandably loath to give up. Such resistance was shown at Koobi Fora. Evidence was accumulating from the fauna which made clear an apparent time disjunction between there and other sites, particularly the Omo, only a few tens of kilometres distant. A number of ingenious explanations were devised to account for this disparity, before fresh dating, and more detailed work on the quite complicated stratigraphy, showed that earlier correlations were simply wrong. The hominids and artefacts are comparable in age to the oldest of their kind found elsewhere in East Africa, such as those from Olduvai. While slightly tarnishing the tinsel, this does little to reduce the area's scientific appeal.



Palaeontology is more than a description of biological events that just happen to have taken place in the past, and more than a simple narrative of phylogenetic histories. This present volume is an important work, and should in no sense be seen as a mere epitaph to these departed beasts. Rather it provides the basic data which, when taken with comparable information from other sites, could answer fundamental biological questions in evolution and ecology that neontology's perspective, limited as it is to extant creatures and communities, is too narrow to solve. □

Andrew Hill is a Research Fellow at Harvard University.

● *Pluto's Republic*, Sir Peter Medawar's foray into "the intellectual underworld", has recently been published in paperback. The book first appeared in 1982, and in his review (*Nature* **300**, 118; 1982) Stuart Sutherland wrote of Medawar's "Johnsonian thump of common sense". Publisher of the paperback is Oxford University Press; price is £4.95.

EXAMINE ON FREE APPROVAL WITHOUT COMMITMENT

TWO NEW reliable, up-to-date and complete biotechnology information resources.

Detailed information on every aspect of biotechnology worldwide

An indispensable guide to:

★ Products, services and research
★ Companies ★ Information sources.
★ Government and international agencies

THE INTERNATIONAL BIOTECHNOLOGY DIRECTORY 1984 —

- is thoroughly international
- features a unique BUYER'S GUIDE to products, research and services
- covers both the old and new biotechnologies

The Directory tells you:

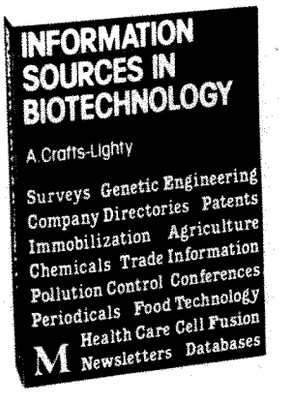
★ Who your competition is, and what they are doing.
★ Who are potential customers and suppliers.
★ Where to buy equipment, chemicals and services.
★ Where culture collections are located and what cultures they hold.
★ Who imports/exports biotechnology products in over 20 countries.
★ Which government departments are associated with biotechnology.

All compiled by the eminent biotechnologist Dr. Jim Coombs and now available to you on **FREE APPROVAL.**

Macmillan Paperback 320pp **September 1983**
ISBN 0 333 36178 4 **£40.00/$80.00**

The ONLY guide to the selection of cost effective biotechnology information sources

★ covers both old and new technologies
★ covers technical and commercial literature
★ covers difficult and hard to trace sources
★ includes over 20 at-a-glance evaluation tables
★ provides an Index of publishers and their addresses



Dr. Crafts-Lighty, Head of Information and Library Services at Celltech Limited, systematically and critically reviews all the important information sources:

• books • conferences • trade periodicals • research periodicals • computer databases • patent • market surveys • directories • organisations • secondary sources

Macmillan Hardcover 400pp **November 1983**
ISBN 0 333 35140 1 **£50.00/$100.00**

At last . . . a rapid-publication monthly for astronomers!

Astronomy Express

Editor: Michael Hoskin *University of Cambridge*

We are pleased to announce the launch of this exciting new current-awareness journal in July this year. Volume 1 of *Astronomy Express* will be published as six monthly issues. Two volumes of six parts each will be published from 1985.

Astronomy Express aims to

★ publish up-to-the-minute information on significant new findings in astronomy, astrophysics and planetary sciences
★ feature news of current developments and trends as well as full-length research papers
★ utilise streamlined submission and refereeing procedures to ensure *speed of publication*
★ use quality paper to allow good reproduction of astronomical photographs
★ make no page charges to contributors (who will also receive a free supply of offprints)
★ offer special subscription rates to individuals – all prices will include rapid delivery by air mail or air speeded delivery

to: Aileen Askwith, Journals Publicity Controller at the Press. North American enquiries should be sent to Harry Florentine in our New York branch.

Please send me

Circle No.12 on Reader Service Card.

IUPHAR 9TH INTERNATIONAL CONGRESS OF PHARMACOLOGY

29 JULY – 3 AUGUST 1984

LOCATION

Barbican Centre for Arts and Conferences, City of London

SCIENTIFIC PROGRAMME

The scientific programme will extend over five days and consist of symposia, invited lectures, pharmacological debates, an educational meeting and free communications, the latter as both oral and poster sessions. The symposia will consist of three simultaneous sessions morning and afternoon and each day there will be four invited lectures. A new feature of the International Conference is the pharmacological debates. In these the intention is to select topics on which there are clear differences in evidence or its interpretation and have the issue debated between protagonists of each view with sufficient opportunity for the audience to participate. In the educational meeting it is hoped to concentrate on the place of various forms of programmed learning in Pharmacology and the instrumentation available. Finally, there will be free communications and to the fullest extent possible authors will be allowed to select whether to give these as oral communications or as a poster.

PROCEEDINGS

The Congress Proceedings are being published by Macmillan Press and may be ordered in advance on the registration form or at the Congress.

SOCIAL EVENTS

A full social programme is being arranged for delegates and accompanying guests. Details are given in the advance programme.

ACCOMMODATION

Accommodation has been reserved at advantageous rates in a number of hotels in various price categories and in student halls of residence. All accommodation is within easy travelling distance of the Barbican Centre.

DATES TO REMEMBER

1 May 1984	Deadline for college accommodation reservations.
18 May 1984	Deadline for receipt of registration at the standard fee (£150). There is a late fee after this date of a further £40. Deadline for receipt of papers for Proceedings volumes.

CONGRESS SECRETARIAT

Advance programmes, registration forms and abstract forms can be obtained from the Congress Secretariat:–

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF CHEMISTRY

POSTDOCTORAL AND POSTGRADUATE RESEARCH ASSISTANTS

required for MRC-funded posts to work on various projects on protein engineering and DNA replication under the supervision of Professor A R Fersht, FRS. One postdoctoral position is available immediately, the other two to start in September 1984. Work will involve protein chemistry and enzyme kinetics, gene cloning and mutation and oligodeoxynucleotide synthesis.

Salary scale: £8,376 — £10,611 for postdoctoral position and £7,496 — £9,716 for postgraduate, inclusive of London Allowance.

Applications (full curriculum vitae and names of two referees) to be sent to Professor A R Fersht, Department of Chemistry, Imperial College, London SW7 2AY. (1228)A

UNIVERSITY OF CALIFORNIA
San Diego

DEPARTMENT OF BIOLOGY

TENURE-TRACK FACULTY

position available July 1, 1984. In the general areas of cell and/or developmental biology. Salary and rank will be commensurate with qualifications and experience. The appointee must have had post-doctoral training and is expected to conduct a vigorous research program. Excellence in teaching and in the pursuit of an independent research program are the criteria to be met.

Applicants should send curriculum vitae, a list of publications, and a brief statement of research interests, by March 30, 1984 to: Ms Joan Turner, Department of Biology B-022, University of California, San Diego, La Jolla, California 92093.

The University of California at San Diego is an equal opportunity/affirmative action employer. (NW306)A

UNIVERSITY OF EDINBURGH

DEPARTMENT OF MOLECULAR BIOLOGY

POST-DOCTORAL RESEARCH FELLOW

Applications are invited for a post-doctoral research position to investigate the molecular structure and function of a novel transposable sequence found in wide host-range IncP plasmids. Experience in molecular genetics or plasmid DNA manipulations is desirable. The appointment is available from 1st March 1984 for one year and one month. Salary will be on Research Range 1A.

Applicants should send a cv, references and a letter describing their research interests to Prof N S Willets, Department of Molecular Biology, University of Edinburgh, King's Buildings, Mayfield Road, Edinburgh EH9 3JR.

Please quote reference No 5147. (1200)A

DURHAM UNIVERSITY SENIOR RESEARCH ASSISTANT IN SYNCHROTRON RADIATION RESEARCH

Applications are invited for the post of Senior Research Assistant tenable in the Physics Department for two years from early 1984. The successful applicant will work, under the supervision of Dr B K Tanner, on an SERC supported project to develop X-ray diffraction techniques for the characterization of strains in III-V semiconductors. Part of the work will be carried out on the Synchrotron Radiation Source at Daresbury Laboratory.

Initial salary in the range of £7630 — £8530 on National Range 1A plus superannuation.

Applications (3 copies) naming three referees should be sent by 2 March 1984 to the Registrar, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. (1217)A

Imperial Chemical Industries PLC
Agricultural Division: Billingham: Cleveland
Biochemical Group

Biotechnologists

ICI Agricultural Division has three vacancies within its Biochemical Group of the Research Department.

We require top class scientists to make major inputs to the fields of: fermentation technology, microbiology, enzymology, protein chemistry, separation and enzyme immobilisation technology.

In particular we are looking for:

- a Fermentation Scientist with wide experience of fermentation processes and technology
- a Separation Scientist with experience in protein and polymer separation, enzyme purification and immobilisation.
- a Microbiologist to lead a small team engaged in strain improvement programmes for the microbial production of enzymes and metabolites.

The Division's Research Department has an excellent record of scientific innovation backed by strong commercial and engineering resources. This combination has placed ICI in the forefront of the developments in Biotechnology.

Applicants should possess a good honours degree in the appropriate discipline with a PhD demonstrating original thinking and commensurate technical skills. Post Doctoral or industrial/academic experience whilst desirable is not essential, but more mature candidates with this background are encouraged to apply.

Remuneration will be commensurate with qualifications and experience. The Company operates house purchase, profit sharing and contributory pension schemes and offers financial assistance towards removal expenses.

Applications giving details of age, qualifications and experience should be sent as soon as possible to:-

Mr M A J W Pegg, Personnel Department, Imperial Chemical Industries PLC, Agricultural Division, PO Box No 1, Billingham, Cleveland, TS23 1LB.

(1248)A

INTERNATIONAL CROPS RESEARCH INSTITUTE FOR THE SEMI-ARID TROPICS

(ICRISAT)

ICRISAT

near Hyderabad, India needs

PROGRAM LEADER (Millet Improvement)

To provide scientific and administrative leadership to the program of Millet Improvement at ICRISAT Center under the general supervision of the Director of Research. He will formulate and implement research programs that will meet the program goals set by the Institute. The Millet Improvement Program currently has subprograms in Breeding, Pathology, Physiology, and Microbiology involving 14 scientists. The Program Leader will coordinate research with other programs at ICRISAT Center, and between research at headquarters and in other countries. He will participate in the overall guidance and management of the Institute, in its global activities, and in fostering appropriate institutional interrelationships. *Qualifications:* Doctorate in an appropriate discipline with an excellent academic record, proven ability to lead a team of scientists and contribute to interdisciplinary research programs, and ability to speak and write English well are essential. Substantial experience in plant breeding, at least ten years post-doctorate research experience, and ability to speak French are desirable.

Salary for the position is at principal staff level, according to qualifications and experience, with attractive fringe benefits. Work would be centered at ICRISAT Center (1394 ha) near Hyderabad, India, where excellent scientific and technical support is available. Hyderabad has international airline connections and good living conditions, recreational facilities, and medical and educational facilities (for children to age 10-12 years).

Send résumé and names of three referees by 31 March, 1984, to Director General, ICRISAT Patancheru PO 502 324, Andhra Pradesh, India. (W753)A

PROTEIN BIOCHEMIST

A senior biochemist is required to join a team working on scrapie and the related unconventional slow infections of the CNS. The appointee will be expected to develop and lead an innovative research programme to characterise (a) the infectious unit of scrapie (b) a gene product controlling the disease (c) cerebral amyloid and (d) scrapie-associated fibrils.

Applicants should have a good honours degree in chemistry or biochemistry and a PhD or the equivalent. A considerable proven research record in protein biochemistry is essential, proferably with experience in the analysis of hydrophobic proteins. The appointment will be as Principal Scientific Officer with salary in the range £11,343 – £14,931.

Applications giving full curriculum vitae and names of two referees to The Secretary, AFRC MRC Neuropathogenesis Unit, West Mains Rd., Edinburgh EH9 3JF. (1176)A

TRANSGENE

As a consequence of continued growth and expansion, and of a recent move into new, larger premises, TRANSGENE, a leading genetic engineering company based in STRASBOURG, FRANCE, has immediate openings in the following positions.

– SENIOR MOLECULAR BIOLOGIST

with extensive experience in eukaryotic cell vectors and in the expression of foreign proteins in cultured cells.

– BACTERIOLOGIST

with research experience in the physiology and genetic manipulation of microorganisms of industrial importance (the streptococci, lactobacilli, streptomyces . . .).

– MOLECULAR BIOLOGIST

with 2-3 years practical experience of cDNA cloning techniques.

– PROTEIN CHEMIST

with practical experience in the synthesis of peptides.

TRANSGENE is an independent recombinant DNA research and development company, backed by a group of major French industrial and financial organizations.

Interested candidates are invited to submit, in confidence, a full curriculum vitae, a list of publications, and the names and addresses of three referees to:

Dr. J. P. LECOCQ
Scientific Director
11 rue de Molsheim
67000 STRASBOURG
FRANCE

RESEARCH ASSOCIATE IN STRUCTURAL BIOCHEMISTRY AND MASS SPECTROMETRY

The Department of Pharmaceutical Chemistry and the NIH National Mass Spectrometry Resource at UCSF have a long-term staff position at the Adjunct Assistant or Adjunct Associate Professor level available immediately with a salary range from $23,000 – $38,000. We are seeking an individual with experience in elucidation of structures of peptides and proteins including hormones, peptide mapping of cloned gene products, covalently modified proteins, antigenic determinants and/or substrate receptor complexes. The person must have experience in peptide and protein chemistry, photoaffinity labeling and sequencing by biochemical as well as mass spectrometric techniques. A strong candidate with appropriate isolation, degradation, and structural characterization credentials and a strong interest in learning the present advanced techniques of mass spectrometry will also be considered. The successful applicant will be expected to develop a strong core and collaborative research program, devote a portion of his/her effort to interdisciplinary training and service projects, and contribute to graduate teaching.

Applicants should sumbit curriculum vitae, a brief description of their proposed research and teaching interests, copies of their reprints and manuscripts, and three letters of recommendation to Prof. A. L. Burlingame, Dept. of Pharmaceutical Chemistry, University of California, San Francisco, CA 94143. The University is an Equal Opportunity/Affirmative Action employer. Women and minorities are encouraged to apply. (NW307)A

Synthetic Organic Chemists For Drug Discovery

In the middle of 1984, as part of a major expansion programme, we shall be opening an additional 70,000 sq ft of laboratory and office space at our research centre at Sandwich, Kent. This will enable us to increase our commitment to human drug research, especially in the cardiovascular area.

We are looking for:

A Project Leader

to take charge of one of our cardiovascular projects.

Our need is for a synthetic organic chemist with 6/10 years' post-doctoral experience, mainly in the drug industry. He/she will probably be leading a small team already and seeking to broaden his/her responsibilities as a scientist. Experience in the cardiovascular area would be preferable but not essential.

Three Post-Doctoral Chemists

with experience in synthetic organic chemistry coupled with a desire to discover drugs. Close collaboration with biological colleagues is essential in our multi-disciplinary project teams.

Our need here is for one chemist with 3/5 years' research experience in the pharmaceutical or agricultural/veterinary industry and two chemists who are completing 2/3 years' post-doctoral research.

Graduate/GRSC/LRSC Chemists

We need several young, energetic chemists experienced in modern methods to synthesise novel molecules for biological evaluation.

Pfizer

Our laboratories are modern and well equipped with up-to-date instrumentation and support services. All our chemists have ready access to the Research Division computers and molecular graphic techniques are used regularly to aid the design of biologically active molecules.

If you have the necessary qualifications and experience and want to further your career in drug discovery please send your cv to: **D. W. Sells, Personnel Manager, Pfizer Central Research, Ramsgate Road, Sandwich, Kent CT13 9NJ.**

If you have applied for a similar position with us in the past two years your previous application will be considered automatically; there is no need to reapply. All applications will be treated in strict confidence.

(1216)A

1979

Reproductive Biologist

Experienced embryologist with Ph.D. required to manage busy laboratory and devoted to both service and research of human infertility.

Facilities include a successful IVF programme (16 delivered infants to date) gamete and embryo cryopreservation, techniques for the study and treatment of oligospermia, the induction and intensive monitoring of ovulation and active research into the causes and treatment of early pregnancy wastage.

The laboratory has a nucleus staff of 3 biologists and 2 technologists and is linked to a large private Infertility Clinic with research undertaken in affiliation with the University of Western Australia. The successful applicant is expected to manage the laboratory, supervise research projects and liaise with the clinical staff to optimise patient management.

Salary negotiable in keeping with applicant's experience and expectations.

Apply by 31st March 1984 with detailed curriculum vitae to:
Dr. J.L. Yovich, Director, PIVET Laboratory, 442 Barker Road, Subiaco, Western Australia. Tel: 09-382-1677.

IMMUNO

SABBATICAL LEAVE IN SPANISH LABORATORIES

In order to promote the interaction between the Spanish Scientific Community and scientists working outside Spain, the CAICYT (Spanish National Council for Research & Development) is launching a program encouraging scientists to spend their Sabbatical leave in Spanish Laboratories. The maximum length of stay is one year and the Program will be in operation from 1st September 1984 to 31st July 1986. The visiting scientists will receive a salary that will be awarded on the basis of qualifications and of the percentage of their current salary that is maintained by their home institution. Also some funds for expendable material in the receiving institution will be provided.

Scientists willing to take part in this Program are requested to contact the Spanish laboratory in which they intend to stay. The CAICYT will also help, on request, to establish a connection between Scientists eventually interested in the Program and those Spanish laboratories working in their area of interest. These contacts should result in a joint proposal that must be submitted to CAICYT before 1st June 1984.

Full details of the data that will be required are available either from the Spanish institutions or from CAICYT. The selected candidates will be notified not later than 1st July 1984.

All information concerning this advertisment should be requested from *Dr. Marisa Pacios, Caicyt, Edificio Torre Rioja, calle Rosario Pino, 14-16, Madrid 20, Spain. Tel: (34)-1-4501063.* (W752)A

PREMIER'S DEPARTMENT
THE AUSTRALIAN MUSEUM

SCIENTIFIC OFFICER

Curator of Birds or Mammals, (one position) Position No: AUS 83/11. Wage: A$17,110 range A$37,751. Subject to certain conditions, successful applicants may be eligible for reclassification as research scientist/senior research scientist/principal research scientist, with progression to $A39,051.

Qualification: Essential — University degree in zoology with research experience in an appropriate field. Applicants should have some knowledge of modern museum curatorial practice. Research interests should be orientated towards work which involves the use of the collections, with research on systematics (especially at supraspecific levels), evolutionary biology and biogeography preferred. A wide knowledge of mammalian or avian biology is essential and is more important than a thorough knowledge of Australian mammals or Birds. Duties: To curate the mammal or bird collections and to be responsible for the answering of public and professional scientific enquiries. To participate in the museum's display and educational programmes in the appointee's field of study, and to carry out an active programme of research in some field of Australian mammalogy or ornithology. Conditons: Subject to certain conditions, the successful applicant will be eligible for: payment of fares to Sydney, Financial assistance towards cost of removal expenses, and Financial assistance towards initial accommodation expenses.

Enquiries: Telephone (02) 339-8111 (Dr. Cogger). Applications are to be sent to the Staff Clerk, The Australian Museum, 6-8 College Street, Sydney 2001, by 10 April, 1984. (W751)A

THE UNIVERSITY OF CALGARY

Department of Chemistry Graduate Studies

Chemistry: Analytical, Inorganic, Organic, Physical and Theoretical Chemistry, and Applied Chemistry in projects dealing with Energy Conversion, Oil Sands Recovery, Sulphur Chemistry, and Synthetic Membrane Technology.

Programs leading to PhD and MSc degrees; Excellent laboratory, instrument, and library facilities; Minimum stipend of approximately $10,000 p.a. for Teaching and Research Assistantships; Maximum stipend of approximately $13,000 p.a. for outstanding students holding Scholarship combined with part-time Teaching Assistantships; Program fees remitted for full-time teaching appointments; travel allowance available.

For further information and descriptive brochures write to the following, indicating field of interest:

Chairman of Graduate Studies
Department of Chemistry
The University of Calgary
Calgary, Alberta T2N 1N4
Canada (NW192)A

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF PHYSIOLOGY

UNIVERSITY LECTURER

Applications are invited for a University Lectureship, the appointment to commence on 1 October 1984. Candidates should hold a Ph.D. degree in some area of physiology, or a Medical or Veterinary qualification together with some experience of physiological research.

The appointment will be for three years, with the possibility of reappointment to the retiring age.

The pensionable scale of stipends, for persons not ordinarily resident in college, is £9,875 a year, rising by eleven annual increments to £15,085. There is no grade of Senior Lecturer.

Further information about the duties and conditions of appointment may be obtained from the Secretary of the Appointments Committee for the Faculty of Biology 'B', 19 Trumpington Street, Cambridge, CB2 1QA, to whom applications (12 copies), including a curriculum vitae, list of publications and the names of not more than three referees, should be sent so as to reach him not later than 1 April 1984. A candidate resident overseas may submit only one copy of an application. (1229)A

APPLICATIONS are invited for the post of a Temporary Research Technician Grade 5 to work on enzyme activity in field crops. The work is based at the University farm at Bramham where accommodation may be available. The appointment is for 10 months starting 1st March or as soon as possible thereafter at a salary of £6,279 pa. Applicants should have HNC or a Degree and relevant experience. Apply to Professor J Elston, Department of Plant Sciences, Agricultural Sciences Building, Leeds University LS2 9JT. (1223)A

PURDUE UNIVERSITY

LABORATORY OF RENEWABLE RESOURCES ENGINEERING

POSDOCTORAL POSITION AVAILABLE IMMEDIATELY

Applicants should have background in Microbiology, Molecular Genetics and/or Protein Chemistry. Experience in recombinant DNA, DNA-sequencing, and protein purification, particularly the latter is desired; nevertheless, interest and enthusiasm are equally important. Stipend is competitive.

Send curriculum vitae, transcripts, description of current research interests and objectives, and three letters of recommendation to: Dr N W Y Ho, Molecular Genetics Group, Laboratory of Renewable Resources Engineering, Purdue University, West Lafayette, IN 47907. Purdue is an equal opportunity/affirmative action employer. (NW297)A

UNIVERSITY CHEMICAL Laboratory, Cambridge. Applications are invited for a position as a post-doctoral assistant (SERC-funded in the IA salary scale, £8,080-£8,530) to work with Dr Ian Fleming on stereocontrolled organic synthesis using silicon-containing compounds. Appointment will be for up to 2 years starting 1 Oct 1984. Curriculum vitae and the names of 2 referees should be sent to Dr Ian Fleming, University Chemical Laboratory, Lensfield Road, Cambridge CB2 1EW. (1203)A

THE KENNEDY INSTITUTE

POST DOCTORAL RESEARCH FELLOW

Applications are invited for a Cellular or Molecular Biologist to join an active group led by Dr T E Hardingham and Professor H Muir FRS investigating the molecular basis of articular joint function. Previous experience investigating phenotypic expression in primary cell culture or mRNA isolation, in vitro translation and development of cDNA probes would be an advantage. The post is available immediately and is funded by the MRC until November 1986. Starting salary up to £10,161 (including London allowance) depending on age and experience.

Applications, together with the names of two referees, should be sent to the General Secretary, Mathilda and Terence Kennedy Institute of Rheumatology, 6 Bute Gardens, London W6 7DW. (1231)A

Allelix INC

POST-DOCTORAL RESEARCH Positions in MOLECULAR BIOLOGY

Allelix Inc., Canada's first major biotechnology company, has a number of post-doctoral positions available within the Molecular Biology Division. Applications are particularly invited from young scientists with experience in yeast molecular biology/genetics who will be available in the near future, but molecular biologists of all backgrounds are encouraged to apply, as emphasis will be placed on scientific ability rather than field of experience.

Allelix provides the opportunity to learn from and interact with experienced staff scientists in addition to the immediate project leader, in a well-equipped modern laboratory with strong links to local universities. Salaries benefits are at fully competitive levels.

Interested candidates are asked to send complete résumés, including three references and quoting file number 0061, to:

Dr. R. W. Davies
Allelix Inc.
6850 Goreway Drive
Mississagua, Ontario
L4V 1P1

(NW291)A

SANDOZ, a world leader in the development of ethical pharmaceuticals, has an opening in Preclinical Research for a well-qualified

Pharmacologist

to work on the development of new drugs for the treatment of degenerative diseases of the CNS, particularly senile dementia.

The successful candidate will be responsible for designing and supervising *in vivo* and *in vitro* experiments to elucidate the central and peripheral pharmacological profiles of newly synthesized compounds.

Applicants for this permanent post should have relevant post-doctoral experience in the use of classical and modern pharmacological techniques, and should be keen to work as a member of a multidisciplinary team comprising medicinal chemists, biochemical and behavioural pharmacologists, and electrophysiologists. The candidate should desire to pursue a research career, and will be expected to initiate and design scientific projects.

Applications, including a detailed curriculum vitae, should be addressed to:

Sandoz LTD.,
The Personnel Department, Ref. 8415
CH-4002 Basle, Switzerland (W757)A

SANDOZ

WANTED a young scientist with expertise in immunology or virology for a tenure track position with guaranteed funding for five years and a joint appointment in the Departments of Opthalmology and Microbiology at the College of Physicians & Surgeons of Columbia University. Candidate will be expected to develop an independent vision oriented research program. Interested candidates should send their curriculum vitae and names of three references to either: Peter Gouras, MD, Director of Research, Department of Opthalmology or Harold Ginsberg, MD, Chairman, Department of Microbiology, College of Physicians & Surgeons, Columbia University, 630 W 168 St, New York, NY 10032. (NW292)A

UNIVERSITY OF OXFORD IN ASSOCIATION WITH WORCESTER COLLEGE

UNIVERSITY LECTURERSHIP IN PHARMACOLOGY

Applications are invited for the above post. Stipend according to age on the scale £7,190 to £15,085.

The successful candidate may be offered a stipendiary Tutorial Fellowship by Worcester College. Details from: Sir William Paton, Department of Pharmacology, South Parks Road, Oxford OX1 3QT, to whom applications (nine typed copies; two for overseas applicants) with the names of three referees should be sent by 30 April 1984. (1215)A

WASHINGTON UNIVERSITY SCHOOL OF MEDICINE POSTDOCTORAL RESEARCH FELLOW

Available immediately. Applications are invited for a 2-3 year postdoctoral research appointment in molecular biology/protein chemistry to investigate structure/function of oncogenes, growth factors, and transforming proteins.

Apply with curriculum vitae and two references to Dr Thomas F Deuel, Division of Hematology, Washington University School of Medicine, 216 S Kingshighway, St Louis, MO 63110. (NW271)A

UNIVERSITY OF UTAH

DEPARTMENT OF BIOENGINEERING

Applications from candidates with an earned doctorate are invited for one/two tenure track faculty positions, assistant to full professor level. The appointee(s) will teach courses in bioengineering and will be expected to conduct an outstanding independent program of research. Joint appointments with other departments possible.

Send curriculum vitae and three recent publications to: Prof Richard A Normann, Department of Bioengineering, University of Utah, Salt Lake City, Utah, 84112. Application deadline April 15, 1984. An affirmative action/equal opportunity employer. (NW294)A

ARMAGH OBSERVATORY

Armagh, N. Ireland

RESEARCH ASTRONOMER

Applications are invited for the post of Research Astronomer tenable from 1st June 1984. Salary will be at an appropriate point on the University Lecturer's scale £7,190 — £14,125 p.a. according to qualifications and experience. Applicants should send a detailed curriculum vitae and the names of three referees before 31 March 1984 to The Secretary, Armagh Observatory, Armagh BT61 9DG, N. Ireland from whom further particulars may be obtained. (1235)A

THE UNIVERSITY OF SHEFFIELD

WEST RIDING CHAIR OF MICROBIOLOGY

Applications are invited for the above Chair, which fell vacant on the appointment of Professor J R Quale, FRS to the Vice-Chancellorship of the University of Bath.

The Chair will be tenable from 1 October 1984. Salary in the range for professorial appointments (average £20,300: minimum £17,275).

Particulars from the Registrar and Secretary (Staffing), The University, Sheffield S10 2TN to whom applications (one copy), quoting the names of three referees, should be sent by 5 March 1984.

Quote ref: R32/G. (1134)A

POSTDOCTORAL Position. Available immediately, to study gene expression and recombination in mammalian cells using a bovine papilloma virus vector. Involves gene cloning, cell transformation, and somatic cell genetics. Experience in nucleic acid biochemistry desirable. Send CV and names of references to: Dr William T McAllister, Department of Microbiology, University of Medicine and Dentistry of New Jersey — Rutgers Medical School, PO Box 101, Piscataway, New Jersey 08854. An Equal Opportunity/Affirmative Action Employer. (NW289)A

MEDICAL RESEARCH COUNCIL NATIONAL INSTITUTE FOR MEDICAL RESEARCH DIVISION OF PARASITOLOGY

A postdoctoral protein chemist is required for a WHO funded fellowship for a period of up to three years studying surface antigens of schistosomes. Experience in protein purification, peptide analysis and microsequencing is essential.

The salary will be in the range £8,530 - £10,250 per annum plus £1,186 London allowance, with superannuation provision.

Applications should include a curriculum vitae and the names of two referees and should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA, before 16th March 1984, quoting ref: P/5/SRM. (1210)A

Post Doctoral Scientists Biochemistry/Biochemical Pharmacology

SmithKline Beckman, a leader in pharmaceutical research, is seeking Post Doctoral Scientists to work with Dr. Philip Schein in an environment designed to foster creative, innovative research and to promote personal and professional growth.

We consider post doctoral studies to be of major importance in an individual's career and encourage publication of findings in leading journals and a full interaction with the scientific community.

Our postdoctoral appointments are of 1 year duration and with mutual agreement, renewable for a 2nd year. The successful candidates will join a multidisciplinary team whose goal is to understand the biochemical mechanism of anticancer agent cytotoxicity and tissue-specific selectivity. We are particularly interested in seeking individuals who can make a significant contribution to one of the following current programs:

- structure-activity analyses of sites of alkylating agent binding and repair in transcriptionally active chromatin and chromatin substructure.
- define methods of modulating the structure and function of chromatin.
- determination of sites within chromatin which are critical for alkylating agent cytotoxicity.
- identification of anticancer agents that have specificity for neoplastic tissue.

Candidates are required to have a Ph.D. in Biochemistry and/or Biochemical Pharmacology with 0-3 years post doctoral experience.

Preference will be given to candidates having a strong background in biochemistry/ biochemical pharmacology and relevant publications in major scientific journals.

We offer excellent compensation and benefits and an attractive relocation policy. For confidential consideration, send your CV and names of three references to: Mr. Walter B. Flagg, **SMITHKLINE BECKMAN CORPORATION,** 1596 Spring Garden Street, Philadelphia, 19101. We are an equal opportunity employer, M/F/H/V.

UNIVERSITY OF KONSTANZ
Federal Republic of Germany

RESEARCH FELLOW ELECTROPHYSIOLOGY

Applications are invited for the above position to work on the electrophysiology of active ion transport in cell membranes.

Applications, with curriculum vitae, giving details of experience and the names of two referees should be sent to Prof. Dr. P. Läuger, Department of Biology, University of Konstanz, post-office-box 5560, D - 7750 Konstanz / Germany.

(W759)A

PUBLIC HEALTH LABORATORY SERVICE BOARD
PHLS Centre for Applied Microbiology and Research
MICROBIAL TECHNOLOGY LABORATORY

A Post-graduate Biochemist is required to evaluate novel support matrices for the large scale affinity chromatography of proteins. This post is sponsored by the Engineering Sciences Division of AERE Harwell under the auspices of the BIOSEP project and is available for one year in the first instance. Applicants should have a PhD or an equivalent research qualification. Experience in the purification of proteins on a larger than normal laboratory scale and some understanding of the engineering aspects of large scale chromatography is desirable.

Appointments, subject to qualification and experience will be made on the post-probationary basic grade scale, £6,520 – £8,349. NHS terms and conditions will apply.

Applications with full curriculum vitae and the names and addresses fo two professional or academic referees should be sent to: Mrs. M. Bushby, Personnel Officer, PHLS Centre for Applied Microbiology and Research, Porton Down, Salisbury, Wiltshire SP4 0JG. Candidates seeking further information should contact Dr. M. Scawen on Idmiston (0908) 610391 extension 220.

Closing date for applications will be 2 March 1984. (1236)A

STATE UNIVERSITY OF NEW YORK
POSTDOCTORAL BIOPHYSICS AND PHYSIOLOGY

Intracellular recording and patch clamping. Contact K N Leibovic, Department of Biophysics, Suny at Buffalo, 14214. (716) 831-3249 or 836-5837. (NW287)A

CENTRAL BIRMINGHAM HEALTH AUTHORITY
Birmingham Maternity Hospital
BASIC GRADE CYTOGENETICIST

Applications are invited for a Basic Grade Cytogeneticist. The Cytogenetics Laboratory is situated in the Infant Development Unit at the above Hospital. This Laboratory provides a comprehensive service for the Birmingham area and a large part of the West Midlands Region. Applicants should hold a 1st or 2nd Class Science Honours Degree. The salary scale is £6,277 – £7,953 per annum.

Arrangements to visit the Laboratory may be made with Mrs S Bowser-Riley, Principal Cytogeneticist.

For an application form and job description, please telephone the Personnel Department on 021-472 1377 ext 118.

Closing date: Thursday 1st March 1984. (1206)A

UNIVERSITY OF THE WITWATERSRAND JOHANNESBURG
MRC/UNIVERSITY CIRCULATION RESEARCH UNIT
ASSISTANT RESEARCH OFFICER

Applications are invited from suitably qualified persons, regardless of sex, race, colour or national origin for appointment to the post of Assistant Research Officer in the University Circulation Research Unit.

The Assistant Research officer will be expected to participate in an on-going programme on the control of coronary blood flow in health and disease, as well as the biochemistry of autonomic receptors in the cardiovascular system. Applicants should have at least a BSc Honours degree with a background in physiology, biology, zoology biochemistry or veterinary science.

The salary attached to this post wil be within the range R9,075 – R14,21' per annum. A pensionable allowanc of 12% is also payable. The initia notch will be determined by th qualifications and experience of th successful applicant.

Intending applicants should obtair the information sheet relating to thi post from the Secretary, Soutl African Universities Office Chichester House, 278 High Holborn London WC1V 7HE, England o from the Assistant Registra (Academic Staffing) University of th Witwatersrand, 1 Jan Smuts Avenue Johannesburg 2001 South Africa wit whom applications should be lodge not later than 31 March 1984.

Ethical Pharmaceuticals

Director of Research

S E England — Not less than £30,000 + car etc

My client is a profitable, sizeable and autonomous subsidiary of one of the world's most prestigious drug companies. In the UK it is engaged in the research, manufacture and marketing of a wide range of ethical pharmaceuticals.

It now wishes to appoint a new Director of Research, who will earn and use the support of a young, energetic and interested Board and prove worthy of appointment to it. Reporting to the Managing Director, the Director of Research will have full responsibility for the considerable Research Function, its enviable facilities and more than 200 staff.

The highest academic research record is vital; skills in leadership, management and development of the research teams must combine with a wholehearted and effective input to this multinational's research operations worldwide for the discovery of drugs that are medically valuable and commercially viable.

If you are interested in the very real challenge and rewards (salary will not be a limiting factor) of this job, write or phone me, Mrs. Indira Brown, Corporate Resourcing Group Ltd., 6 Westminster Palace Gardens, Artillery Row, London SW1P 1RL. Telephone: 01-222 5555. As an independent consultant, I shall treat your enquiry with complete discretion.

UNIVERSITY OF ARIZONA

ASSISTANT/ASSOCIATE PROFESSOR

Microbiologist/Immunologist

Applications are being invited for several tenure track positions in the recently reorganized Department of Microbiology and Immunology at the Assistant or Associate Professor level, to begin summer-fall semester, 1984. Duties include teaching undergraduate students, medical students, and graduate students, and conducting an independent research program. Research interests should be within the broad area of microbiology/immunology. Individuals with a strong background in immunology, pathogenics, bacterial physiology, and virology are particularly being sought. The successful candidate must have a doctoral degree and a record of excellence and productivity in scholarly work. Postdoctoral experience is preferred.

Qualified applicants should send a résumé and arrange to have three letters of recommendation sent to Professor William Meinke, Search Committee Chairman, Department of Microbiology and Immunology, College of Medicine, University of Arizona, Health Sciences Center, Tucson, Arizona 85724. Complete applications should be received by April 1, 1984. The University of Arizona is an Equal Opportunity/Affirmative Action Employer. (NW279)A

THE MEDICAL COLLEGE of ST. BARTHOLOMEW'S HOSPITAL (University of London) and ST. MARK'S HOSPITAL for DISEASES OF THE RECTUM AND COLON (The City & Hackney Health Authority)

SENIOR LECTURER

(HONORARY CONSULTANT) IN HISTOPATHOLOGY

Applications are invited for the post of whole-time Senior Lecturer (Honorary Consultant) in Histopathology at St. Mark's Hospital for Diseases of the Rectum and Colon and in the Medical College of St. Bartholomew's Hospital.

This newly estabished post is wholly funded by the Imperial Cancer Research Fund and is tenable for a period of ten years in the first instance. The successful applicant will work in the ICRF Colo-rectal Cancer Unit at St. Mark's Hospital. Clinical duties in histopathology will be largely confined to furtherance of the ICRF colo-rectal cancer studies. Some undergraduate and postgraduate teaching will be undertaken at St. Mark's and St. Bartholomew's Hospital Medical College.

The salary will be on the Senior Lecturer/Consultant scale.

Candidates are invited to discuss the post with Dr B. Morson at St. Mark's Hospital (01-253 1050), with Prof G. Slavin at St. Bartholomew's Hospital (01-600 9000 ext 2865) and with the Dean of the Medical College (01-606 7404). Copies of the job description can be obtained by telephoning 01-606 7404.

Applications, in the form of a curriculum vitae (10 copies please — overseas applicants 1 copy) should be sent to the Dean of the Medical College, West Smithfield, London EC1A 7BE, together with the names of three referees, by Monday 16th March 1984. (1197)A

POSTDOCTORAL Position Available to Study (1) the nucleic acid-protein interaction, (2) the mechanism and regulation of gene expression in both prokaryotic and eukaryotic systems, using biophysical, biochemical or recombinant DNA techniques. Applicant should send curriculum vitae and three letters of recommendation to Professor Cheng-Wen Wu, Department of Pharmacological Sciences, SUNY Stony Brook, Stony Brook, NY 11794. SUNY Stony Brook is an equal opportunity/affirmative action employer. AK No 21-84. (NW303)A

JOHN INNES INSTITUTE

DEPARTMENT OF APPLIED GENETICS

HIGHER SCIENTIFIC OFFICER

required to assess genetic variation for photosynthesis in Pisum sativum and to relate this to other physiological and biochemical projects aimed at improving the dried pea crop.

The post, funded by the Perry Foundation, will be initially for one year, but with the expectation of an extension for a further two years.

Applicants should possess a First or Upper Second Class honours degree plus at least two years relevant post qualifying experience and have a working knowledge of techniques for determining net CO_2 exchange. A PhD would be preferred.

The salary on the Higher Scientific Officer scale will be in the scale £7149 — £9561. Non-contributory superannuation.

Applications, quoting reference AG/155, giving full particulars and experience and the names of two referees, should be sent to the Secretary, John Innes Institute, Colney Lane, Norwich, NR4 7UH, not later than 9 March 1984. (1219)A

MRC CELL BIOPHYSICS UNIT

Applications are invited for a three-year, short-term

POSTDOCTORAL RESEARCH POSITION

available from 1 October 1984, to work on the molecular biology of dedifferentiation and morphogenesis in amphibian limb regeneration. This position is part of a collaboration between Dr Jeremy Brockes and Dr Roger Patient involving the analysis of gene expression in relation to these phenomena. Recent studies have led to the development of monoclonal antibodies as markers for blastemal and differentiated cell types both in vivo and in vitro; further studies will also involve the application of nucleic acid methodology. Experience in recombinant DNA techniques would be an advantage.

The salary will be on the scale £8,376 — £11,896 inclusive per annum; MRC superannuation scheme.

Applications with the names and addresses of two referees should be sent by 29 February 1984 to Mr D M Drummie, MRC Cell Biophysics Unit, King's College London, 26-29 Drury Lane, London WC2B 5RL; telephone 01-836 8851. (1159)A

ROTHAMSTED EXPERIMENTAL STATION
Harpenden, Herts, AL5 2JQ

SCIENTIFIC OFFICER/ HIGHER SCIENTIFIC OFFICER — MOLECULAR BIOLOGIST

Applications are invited for a Scientific Officer/Higher Scientific Officer to join a team in the Biochemistry Department involved in the isolation and transfer of plant genes between crop plant species. The work will involve the characterisation of cDNA and genomic clones and ultimately the study of the expression of transferred genes. The person appointed is likely to be a graduate in Biochemistry or a related subject and with practical experience in some aspects of recombinant DNA technology. The work is funded by the EEC and involves collaborative work with other European laboratories. The appointment is from May 1st, or as soon as possible thereafter, for a period up to March 1986.

Qualifications: First or upper second class honours degree in Biochemistry or related subject with at least two years relevant post-qualifying experience for HSO.

Appointment in grade of Scientific Officer (£5,682 — £7,765) or Higher Scientific Officer (£7,149 — £9,561). Non-contributory superannuation.

Apply in writing to the Secretary giving names and addresses of two referees and quoting Ref: 548 by 9th March 1984. Further details on request. (1243)A

University of Oxford Sir William Dunn School of Pathology

MEMBRANE BIOCHEMIST/ MOLECULAR BIOLOGIST

Grade IA Salary £7190–£11,615

Applications are invited for a postdoctoral research position, funded by a programme grant from the Medical Research Council. The research concerns the characterisation of macrophage plasma membrane antigens with a view to further studies on gene expression in macrophages. Experience in membrane biochemistry, immunochemistry and/or molecular genetics is essential. The appointment, starting as soon as possible after 1 June 1984, is likely to be for five years. Applications, including curriculum vitae and the names and addresses of two referees, should be sent to Dr. S. Gordon, Sir William Dunn School of Pathology, South Parks Road, Oxford OX1 3RE (1234)A

POST DOCTORAL research position available, industry funded, to study the energy metabolism of anaerobic bacteria. Experience in bioenergetics, membrane transport and/or anaerobic organisms desirable. Please send your curriculum vitae and names of three references to Dr Eva R Kashket, Department of Microbiology, Boston University School of Medicine, 80 E Concord St, Boston, MA 02118, US. An affirmative action/equal opportunity employer. (NW299)A

THE UNIVERSITY OF LEEDS

PROCTER DEPARTMENT OF FOOD SCIENCE

LECTURER

Applications are invited from Biochemists or Chemists for the above post. The successful applicant will be required to develop an interest in meat science and in modern developments in the processing of animal products.

Salary on the scale for Lecturers (£7,190 — £14,125) according to age, qualifications and experience.

Informal enquiries should be made to Professor David S Robinson, telephone (0532) 431751, ext 540.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference no 72/17, to whom applications should be addressed. Closing date for applications 8 March 1984. (1242)A

ATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

MICROBIOLOGY DEPARTMENT

A RESEARCH SCIENTIST

required to devise and develop new apid methods for estimating the bacriological quality of milk, milk roducts and other foods. The urther development and automation f the direct epifluorescent filtration echnique (DEFT) is envisaged. dditionally, the application of adioimmune, ELISA, and allied echniques for food analysis will be xplored.

Appointment will be as Scientific Officer (£5,682 — £7,765) or Higher Scientific Officer (£7,149 — £9,561). Non-contributory superannuation.

Candidates should have a First or Upper Second Class Honours degree in biological or physical sciences with at least two years' relevant postqualifying experience for appointment as HSO.

Applications to the Secretary, NIRD Shinfield, Reading RG2 9AT.

Please quote reference 83/19 (1205)A

UNIVERSITY OF GÖTTINGEN

DEPARTMENT OF HUMAN GENETICS

POSTDOCTORAL RESEARCH FELLOW

Applications are invited from persons with a background in recombinant DNA research to work on human genome mapping and the molecular diagnosis of genetic disease. The appointment will be initially for 20 months, from May 1st, 1984, with the possibility of renewal. Knowledge of German is not essential.

Applications including CV and names of two referees should be sent to Dr Jörg Schmidtke, Institut für Humangenetik der Universität, Nikolausberger Weg 5a, D-3400 Göttingen, FRG. (W749)A

UNIVERSITY OF NEW BRUNSWICK

DEPARTMENT OF BIOLOGY

Fredericton Campus requires a

GENETICIST

with expertise in Botany or Plant Science with a main responsibility to teach genetics and to carry out a vigorous research program. The candidate must have a PhD degree and proven ability in research and teaching.

Assistant Professor, 2-year term appointment possibly leading to tenure track, to start July 1, 1984, subject to budgetary approval.

Apply, giving full c/v, a letter indicating the nature of a proposed research program and names of three academic referees to: Dr M D B Burt, Chairman, Department of Biology, University of New Brunswick, Bag Service 45111, Fredericton, NB E3B 6E1.

In accordance with the Canadian Immigration requirements, this advertisement is directed to Canadian Citizens and permanent residents. (NW286)A

WELSH NATIONAL SCHOOL OF MEDICINE

(University of Wales)

DEPARTMENT OF SURGERY

POST-DOCTORAL RESEARCH OFFICER IN CELL BIOLOGY

is required to work on a 3-year project to establish the roles of intracellular regulators in oxygen radical production by phagocytes and their importance in inflammatory diseases. Candidates should have a first degree in a relevant discipline and recently have obtained or submitted a thesis for a PhD. Previous research experience in cell separation, cell culture and fluorescence microscope techniques would be advantageous though not essential. Starting salary up to £7,190 per annum.

Further particulars (quoting ref No S19/2/67) are available from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN to whom application in the form of a curriculum vitae with the names and addresses of two referees should be submitted by 19th March, 1984. (1213)A

UNIVERSITY OF ABERDEEN

CHAIR OF CHEMISTRY

Applications are invited from candidates with a proven record in any branch of chemistry for the Chair of Chemistry which will become vacant on 1 October 1984 following the retirement of Professor P Meares.

Further particulars and application forms from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 23 March 1984. (1221)A

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF PURE AND APPLIED BIOLOGY

POSTDOCTORAL SCIENTIST

required for a three year World Health Organisation-funded project which is part of a new group on the immunology of nematode infections and involves an antigenic analysis of filarial parasites, combining monoclonal antibody production with a range of immunochemical techniques for immunodiagnostic development. There will also be an opportunity for field work in endemic areas. Post available from May 1984, although a later starting date will be considered for suitable applicants. Salary on scale £7,190 — £11,615 plus £1,186 London Allowance.

Further details from Dr R M Maizels, Department of Pure and Applied Biology, Imperial College, London SW7 2BB (01-589 5111 ext 2252) to whom applications should be submitted by 23 March 1984. (1237)A

---

nature

the weekly international journal of science

seeks an unusual sub-editor

to help 500,000 readers keep up with science

Essential qualifications:
Literacy — Zeal — Meticulousness — Tact

Also desirable, **two or more** of the following:
Two years experience as a sub-editor
Wide general knowledge of science
Scientific or technical degree
Work experience in a professional environment
First-hand experience of research

Duties include negotiation with scientist authors of acceptable and intelligible forms of words and preparation of manuscripts for the press. Opportunities for other journalistic work not excluded. Salary by negotiation. Age, Sex, etc. immaterial. Applications from exceptional part-timers considered.

Replies by 8 March with full *curriculum vitae* to the Editor, *Nature*, Macmillan Journals Limited, 4 Little Essex Street, London WC2A 3LF. (1233)A

BIOCHEMIST

The Department of Biochemistry, at the Faculty of Medicine, invites applications for a full-time Faculty Position to commence by the summer of 1984. Appointment is at the Assistant Professor level. Preference will be given to candidates with programmatic expertise in molecular and/or cellular biology with particular reference to mammalian systems; but outstanding candidates in other biochemistry subspecialities will be given full consideration. Post doctoral training and potential for an independent career as an experimental scientist is a prerequisite. An interest in developing expertise and a desire to become an effective educator are desirable qualities.

The position is open to both women and men. In accordance with Canadian Immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada. For full consideration, send a concise description of projected research goals and interests, a list of a minimum of 4 individuals for letters of reference, a curriculum vitae and any additional information to:
Dr. J. N. Kanfer, Department of Biochemistry, Faculty of Medicine, University of Manitoba, 770 Bannatyne Avenue, Winnipeg, Manitoba, Canada R3E 0W3. (NW300)A

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF MICROBIOLOGY

GENE EXPRESSION AND MANIPULATION

Applications are invited for a Postdoctoral Research Assistant financed by the SERC for work on the expression and in vitro mutagenesis of the genes encoding the respiratory succinate dehydrogenase of E coli. Tenable from 1 May 1984 or later, for 17 months.

Initial salary £7,190 — £8,975 a year, Range IA. Experience in molecular genetics or protein biochemistry desirable, but not essential.

Further information, by letter or telephone (0742 — 78555 ext 4406) from Professor J R Guest, Department of Microbiology, The University, Sheffield S10 2TN, to whom applications, including curriculum vitae and the names of two referees, should be sent by 5 March 1984. Quote ref: R36/G (1241)A

The Queen's University of Belfast

POSTDOCTORAL OR GRADUATE RESEARCH ASSISTANT

Department of Agriculture and Food Chemistry

Applications are invited from graduates with either a doctorate or a good honours degreee for a two-year research assistantship funded by the Livestock Marketing Commission for Northern Ireland to investigate the physico-chemical properties of mechanically-deboned beef. The work will include a study of the rheological properties of mechanically-deboned beef in comparison with normal meat systems and an investigation of the functional properties of mechanically-deboned beef to clearly identify its potential for use in food products. Applicants should preferably have experience in the area of meat science or food engineering.

Commencing salary is in the range of £6312 – £8082 per annum, initial placing depending on experience and qualifications.

Further particulars may be obtained from the Personnel Officer, The Queen's University of Belfast, Northern Ireland, BT7 1NN. Closing date: 16th March 1984. (Please quote Ref. 84/N). (1218)A.

CHAIRPERSON
DEPARTMENT OF CELL AND TUMOR BIOLOGY

As a comprehensive cancer center involved in basic, clinical, and educational programs in cancer, Roswell Park Memorial Institute requests nominations or applications for the above position which involves leadership of a major research program in the molecular and cellular biology of cancer and which is presently staffed by sixty individuals, including thirty scientists.

Qualified candidates should minimally posses a PhD or MD degree and have a distinguished record in research on molecular and cellular aspects for cancer and have demonstrated capacities for scientific administration. Preference will be given to individuals with a record of collaborative studies with clinical colleagues on the molecular biology of human cancers.

Applications by qualified women and minority candidates are welcomed. Nominations and applications should be sent to: Dr. Timothy E. O'Connor, Associate Director for Scientific Affairs, Roswell Park Memorial Institute, 666 Elm Street, Buffalo, NY, 14263.

An Affirmative Action, Equal Opportunity Employer.

(NW298)A

UNIVERSITY OF THE WITWATERSRAND JOHANNESBURG

DEPARTMENT OF PHYSIOLOGY

SENIOR LECTURER/ LECTURER

Applications are invited from suitably qualified persons, regardless of sex, race, colour or national origin, for appointment to the above posts in the Department of Physiology. Applicants should hold a higher science degree or a medical or veterinary qualification.

Successful applicants will be expected to participate in the teaching and research programmes of the Department. The major research interests of the Department of Physiology include: cardiovascular physiology, neurophysiology, thermoregulation, biomechanics/ energetics, mathematical biology, and computer simulation.

The Department offers outstanding opportunities for research. In the case of registered medical practitioners arrangements can be made for a remunerated part-time attachment to a clinical department for the purpose of patient care and research.

The salary will be in the range: Senior Lecturer: R22,533 — R28,185 per annum; Lecturer: R14,880 — R25,080 per annum.

A pensionable allowance of 12% is also payable.

The initial salary notch will be determined according to the qualifications and experience of the successful applicants. Benefits include an annual bonus, medical aid, a housing subsidy for those eligible and substantial removal aid.

Intending applicants should obtain the information sheet relating to this post from the Secretary, South African Universities Office, Chichester House, 278 High Holborn, London WC1V 7HE, England or from the Assistant Registrar (Academic Staffing) University of the Witwatersrand, 1 Jan Smuts Avenue, Johannesburg 2001 South Africa with whom applications should be lodged not later than 31 March 1984.

(W755)A

THE UNIVERSITY OF BIRMINGHAM

FACULTY OF MEDICINE AND DENISTRY

CLINICAL GENETICS

A vacancy has arisen in the above department for a Research Associate to work on cytogenetic aspect of mental retardation.

Salary — Research Associate 1B £6310 — £8530 (plus superannuation) for two years.

Further information from Assistant Registrar, The Medical School, Birmingham B15 2TJ to whom applications (three copies) must be sent by 9th March 1984. Quote ref RA/CG/TW. (1247)A

UNIVERSITY COLLEGE DUBLIN
DEPARTMENT OF PHARMACOLOGY

Applications are invited for the following posts which are funded by University College Dublin and the E.E.C. Research and Development Programme in the field of Environment. The project is headed by Dr C. Regan and will investigate the effects of lead toxicity on neuronal cell surface functions believed to be involved in brain development.

RESEARCH ASSISTANT

The successful candidate will be expected to have a good basic degree in a biological science. Experience in tissue culture is advantageous but not essential. Salary will be in the range of IR£4,500 — 5,000 per annum.

POSTDOCTORAL RESEARCH ASSOCIATE

Applicants should possess a PhD degree (or shortly expect to receive one) and have some experience in protein chemistry. Salary will be in the range of IR£7,500 — 8,000 per annum.

Applications, including curriculum vitae and the names of two referees, should be sent as soon as possible to Dr C Regan, Department of Pharmacology, University College, Fosters Avenue, Blackrock, Co Dublin, Ireland. Tel (01) 693244 ext 557. (1239)A

Southampton THE UNIVERSITY

DEPARTMENT OF OCEANOGRAPHY
RESEARCH ASSISTANT PHYSICAL OCEANOGRAPHY/ REMOTE SENSING

A good honours graduate in physical science is required very soon to fill a post in connection with a M.O.D. research contract using satellite data to study the dynamics of the N. Atlantic Ocean. Salary range IB (from £6,310 — £8,530). Enrolment of a research degree encouraged.

Applications with full cv and names of two referees to Dr I S Robinson, Department of Oceanography, University of Southampton, SO9 5NH, UK from whom further information is available.

(1225)A

CHAIRMAN

DEPARTMENT OF ANATOMY

Applications are invited for the position of Professor and Chairman, Department of Anatomy, Schools of Medicine and Dentistry, University of Alabama in Birmingham. We are seeking candidates with research and teaching experience, leadership qualities, and administrative skills. This department has teaching responsibilities for graduate students in anatomy, medical, dental and other students.

Please submit applications and a curriculum vitae to: Antonietta D Hyche, Administrative Officer, University of Alabama School of Medicine, Dean's Office — MEB 306, Birmingham, Alabama 35294. An Equal Opportunity/Affirmative Action Employer. (NW263)A

THE SCHOOL OF PHARMACY UNIVERSITY OF LONDON

DEPARTMENT OF PHARMACOLOGY

LECTURESHIP

Applications are invited from suitably qualified candidates for the above post. The successful applicant will be required to pursue research on fundamental mechanisms of drug action and to contribute substantially to the teaching of pharmacology and/or related subjects to students undertaking the University of London BPharm and BSc Toxicology and Pharmacology degrees.

Salary within the Lecturer range — £7,190 — £14,125 pa + LA £1,186 pa.

Enquiries to Professor D A Brown, Department of Pharmacology, The School of Pharmacy (Tel: 01-837 7651 ext 31).

Applications, including names of two referees, to: Personnel Officer, The School of Pharmacy, 29/39 Brunswick Square, London WC1N 1AX, by 9 March 1984. (1226)A

University College of Swansea

Chair of Mechanical Engineering and Headship of Department

Applications are invited for the Chair and Headship of the Department of Mechanical Engineering from October 1, 1984.

Further particulars may be obtained from the undersigned, University College of Swansea, Singleton Park, Swansea SA2 8PP, to whom applications (15 copies) should be sent by *March 16, 1984*.

V.J. Carney
Registrar
(1198)A

CONFERENCES and COURSES

JAPANESE BIOTECHNOLOGY STUDY TOUR

An in-depth series of site visits, conferences and seminars with some of Japan's leading industrial scientists and executives in biotechnology.

This exclusive study tour is designed to give western scientists and executives an opportunity to become acquainted with the Japanese marketing and research capacity. The mission will be led by Christopher G. Edwards, Editor in Chief of BIO/TECHNOLOGY, and organized by the Technology Transfer Institute. Visits will be conducted throughout Japan from March 31-April 15.

For further information, contact: Technology Transfer Institute — New York, One Penn Plaza, Suite 1411, 250 W. 34th St., New York, N.Y. 10119. 212-947-2648 telex 420057TTIUI. Attention: Mr. Hashizume. (NW174)C

4TH CONFERENCE OF EUROPEAN SOCIETY FOR COMPARATIVE SKIN BIOLOGY

In Grenoble from 3-6 July 1984. Details from Professor P. Sengel, Laboratoire de Zoologie, Université scientifique et medicale de Grenoble, BP N°68, 38402 Saint Martin D'Heres, France. (1212)C

EMBO Course on

RECOMBINANT DNA TECHNIQUES

September 17–29, 1984

National Research Foundation, Athens, Greece

The course will provide training in the basic techniques of molecular cloning. It will be suitable for participants at an advanced predoctoral or post-doctoral level who wish to utilize recombinant DNA techniques in their research. Basic nucleic acid and microbiological techniques will be taught. No previous knowledge of cloning technology will be assumed. Participants will prepare and screen cDNA and genomic clone banks and characterize the isolated recombinants. A lecture programme will cover areas which cannot be included in the practical course and will include invited speakers. The course language will be English. Applications should include a short curriculum vitae, statement of research interests and a letter of recommendation. The registration fee is 5.000 Dr. Upon motivated request some fellowships for board and lodging will be granted.

The closing date for applications is April 30, 1984

Those accepted will be notified not later than June 15, 1984. Applications should be sent to: G.J. Dimitriadis, Biological Research Center, National Hellenic Research Foundation, 48 Vas. Con/nou Av., Athens 11635, Greece (W762)C

Royal Postgraduate Medical School

(University of London)

MSc Degree Course

in Experimental Pathology (Toxicology)

Applications are invited for the above, one-year, full-time course which is being offered from 1 October 1984.

Applicants should possess a first degree in medicine, veterinary medicine or an appropriate science subject.

It is hoped that a number of Medical Research Council Studentships will be available.

Further details and application forms are available from:
School Office (MSc)
Royal Postgraduate Medical School
Hammersmith Hospital
Du Cane Road
London W12 0HS
Telephone: 01-743 2030 ext 351

Please note that the closing date for receipt of applications will be: 11 May 1984. (1195)C

MOLECULAR BIOLOGY FOR IMMUNOLOGISTS A BRITISH SOCIETY OF IMMUNOLOTY

SUMMER SCHOOL Edinburgh July 2nd-4th 1984

This is an introductory lecture course aimed at individuals with little or no experience in the molecular cloning field. The lectures will cover the basic steps included in molecular cloning and will illustrate how recently developed cloning techniques can be used to study both basic immunological systems and in the diagnosis and treatment of disease.

SPEAKERS INCLUDE:

Dr F. Baralle, Oxford.
Professor S. Cohen, London.
Dr D. Cosman, Seattle, U.S.A.
Dr W. Cushley, Glasgow.
Dr S. Emtage, Slough.
Dr F. Grosveld, London.
Dr T. Harris, Slough.
Dr N. Hastie, Edinburgh.
Dr C. Hentschel, Slough.
Dr A. Kingsman, Oxford.
Dr A. Mellor, London.
Professor R. Old, Warwick.
Dr M. Owen, London.
Dr K. Reid, Oxford.
Dr J. Williams, London.
Prof. R. Williamson, London.

Further details of this programme and registration forms can be obtained by writing to Dr Keith James, Education Secretary, British Society for Immunology, Department of Surgery, University of Edinburgh Medical School, Teviot Place, Edinburgh EH8 9AG.

Closing date for applications — 31st May 1984. (1244)C

STUDENTSHIPS

THE OPEN UNIVERSITY

RESEARCH STUDENTSHIPS IN SCIENCE

The Faculty of Science at the Open University invites applications for full-time research studentships, tenable from 1st October, 1984 at Milton Keynes and the Oxford Research Unit. A wide variety of research topics is available within the following Disciplines and research groups:

BIOLOGY including BRAIN RESEARCH GROUP

CHEMISTRY

EARTH SCIENCES including PETROGENESIS RESEARCH GROUP

PHYSICS including OXFORD RESEARCH UNIT

Successful applicants will be awarded either an Open University or Research Council research studentship. Applicants should normally have (or expect to gain in 1984) a good honours degree.

For further particulars and application forms please send a POSTCARD to the Higher Degrees Office S/3, The Open University, PO Box 49, Walton Hall, Milton Keynes MK7 6AD or telephone Milton Keynes (0908) 653806.

PLEASE SPECIFY THE AREA(S) IN WHICH YOU ARE INTERESTED AND QUOTE REFERENCE S/3.

Applications should be submitted as soon as possible.

(1227)F

UNIVERSITY OF NOTTINGHAM MRC INSTITUTE OF HEARING RESEARCH POSTGRADUATE RESEARCH

Applications are invited for MRC Studentship(s) for research in auditory physiology and anatomy leading to a higher degree at the MRC Institute of Hearing Research. Current research emphasises development of structure and function in hereditary deafness, and mechanisms of drug interaction which damage hearing. Students(s) have the opportunity to learn a variety of electrophysiological techniques, scanning and transmission electron microscopy, and computer programming.

The successful candidate(s) will have (or expect to obtain during 1984) at least an upper second class honours degree in any biological subject.

Applications are also invited from those with degrees in any appropriate subject and interested in human experimental work on hearing, covering perception, speech, ergonomics and social factors in disability and service take-up.

For further information, please write to: Dr G Bock, MRC Institute of Hearing Research, University of Nottingham, University Park, Nottingham NG7 2RD. (1209)F

UNIVERSITY OF DUNDEE

THE DEPARTMENT OF PHARMACOLOGY AND CLINICAL PHARMACOLOGY (DUNDEE)

Applications are invited for a

THREE-YEAR ORGANON-SUPPORTED RESEARCH STUDENTSHIP

to work on a project under the supervision of Dr J J Lambert using radioligand binding, patch clamp and other electrophysiological techniques to investigate the action of calcium channel blockers on isolated cardiac myocytes.

Applicants should hold at least an upper second class Honours degree in physiology, pharmacology, biophysics, electronics or related disciplines. Financial conditions are similar to those of an SERC studentship.

For further information please contact Dr J J Lambert, Department of Pharmacology and Clinical Pharmacology, University Medical School, Ninewells Hospital, Dundee, Scotland as soon as possible (Tel Dundee 60111 ext 2527/2161). Applications (including the names of two referees) should be sent to Dr Lambert by 15th March 1984.

(1196)F

UNIVERSITY OF EDINBURGH

DEPARTMENT OF BOTANY

in conjunction with

UNILEVER RESEARCH

COLWORTH LABORATORY

PLANT BIOCHEMISTRY

A case studentship has been awarded for studies on the role of cytoplasmic calcium and membrane-bound protein kinase in controlling the division cycle of cultured plant cells and protoplasts.

Appointment is for 3 years with registration for M.Phil/Ph.D degree. Undergraduates (or graduates) in Biochemistry/Plant Biochemistry or Biology/Botany with a strong physiological or biochemical bias may send applications (c.v. + 2 referees) to Dr. A. Trewavas, Botany Department, University of Edinburgh, Edinburgh EH9 3JH or Dr. W. Hughes, Unilever Research, Colworth House, Sharnbrook, Bedford. (1232)F

UNIVERSITY OF OXFORD

INORGANIC CHEMISTRY LABORATORY

CASE RESEARCH STUDENTSHIPS

Applications are invited for an SERC CASE Studentship with BP Chemicals Ltd as the co-operating industrial body. The studentship is intended to lead to a DPhil degree.

The research project is entitled 'Activation of Carbon Dioxide in Low-temperature Matrices' and preference will be given to applicants having interests and background experience in the methods of vibrational spectroscopy and/or synthetic inorganic or organometallic chemistry.

Applications, with the names of two referees, should be sent to Dr A J Downs, Inorganic Chemistry Laboratory, University of Oxford, South Parks Road, Oxford OX1 3QR. (1240)F

AWARDS

THE UNIVERSITY OF OXFORD GRADUATE AWARDS AT ST. CATHERINE'S COLLEGE

The College proposes to award five Graduate Scholarships of £200 per annum, tenable for two years in the first instance, for men or women commencing a research degree at Oxford in October 1984 in any subject. The awards are intended for those who have taken first degrees at universities within the UK and European Community (except Oxford).

The College also offers a Graduate Scholarship of £1,500 per annum, for two years, and five Bursaries of £200 intended for graduates who are NOT citizens of a European Member State.

Further details may be obtained, before 30 April 1984, from the Senior Tutor, St. Catherine's College, Oxford OX1 3UJ. (1222)N

FELLOWSHIPS

THE ROYAL SOCIETY OF EDINBURGH

ROBERT CORMACK BEQUEST FELLOWSHIP

Applications are invited from 1st Class University Honours graduates for a Robert Cormack Bequest Fellowship in astronomy or subjects directly related thereto, tenable from October 1st, 1984.

Further details and application forms, which should be returned no later than March 31st, 1984, may be obtained from the Executive Secretary, The Royal Society of Edinburgh, 22/24 George Street, Edinburgh EH2 2PQ. (1204)E

NEWNHAM COLLEGE CAMBRIDGE VISITING RESEARCH FELLOWSHIP IN THE SCIENCES

Applications are invited fro academically qualified women wh wish to pursue research Cambridge. The Fellowship, tenab at Newnham College, is for a perio of at most eleven months (between 1 October and 31st August) and may b awarded either for 1984-85 or fo 1985-86.

The purpose of the Fellowship is t enable visitors to the University particularly those on sabbatic leave, to take part in the life of th College while undertaking their ow work. No stipend is offered, bu holders of the Fellowship a provided with a study in College an are entitled to meals without charg at the High Table. If require further living accommodation ma also be provided at a charge to b agreed with the College.

Further information may b obtained from the College Secretar Newnham College CB3 9DF. Th closing date for applications is 31 March 1984. (1207)E

A POSTDOCTORAL Fellowship available in protein crystallograph related to active sites and regulato mechanisms, including enzym modified at the DNA level by recor binant techniques. Applicants fro the area of small molecule cryst lography will also be considere Applicants may write to Pr William N Lipscomb, Gibb Chemical Laboratory, Harvard Un versity, Cambridge, MA 0213 USA. Harvard University is Affirmative Action/Equal Oppo tunity Employer. (NW301)E

THE UNIVERSITY OF LEICESTER

DEPARTMENT OF BIOCHEMISTRY

POST-DOCTORAL FELLOWSHIP

Applications are invited for a po doctoral research position (CR funded) to work on an ongoi project directed toward clarifying t relationship between Tyrosin specific phosphorylation of the cyt skeletal protein vinculin, and t morphology of cells transformed Rous sarcoma virus (RSV).

Methods involved will include c culture (transformation of prima chick cells with RSV), immun chemical and immunofluorescen techniques.

Applicants should have a PhD Biochemistry and experience in so area of Tumour Biology is desirab

Salary £7,190 to £8,975.

The position is availat immediately, although the starti date is negotiable, and will be fo years.

Applications (along with t names of two referees) should be s to Dr D R Critchley, Department Biochemistry, University Leicester, University Road, Leices LE1 7RN. (1202)E

THE UNIVERSITY OF LEICESTER

DEPARTMENT OF BIOCHEMISTRY

POST-DOCTORAL FELLOWSHIP

Applications are invited for a post-doctoral research position (MRC-funded) to work on the interaction between tetanus toxin and neural tissue. The project will include studies on (1) the "receptor" for tetanus toxin (2) the biochemical and ultrastructural features of the internalization process and (3) structure function relationships within the toxin molecule itself.

Techniques involved will be in part similar to those previously developed to study the interaction of cholera toxin with target tissues (J Biol Chem 256 (1981) 8724), but will also involve the extensive use of monoclonal antibodies.

Applicants should have a PhD in Biochemistry or related discipline, and preference may be given to those with experience in cell culture and immunochemical techniques, and with an interest in membranes.

Salary: £7,190 to £8,080.

The position is immediately available although the starting date is negotiable, and will be for a maximum of 3 years.

Applications (along with the names of two referees) should be sent to Dr D R Critchley, Department of Biochemistry, University of Leicester, University Road, Leicester LE1 7RN. (1201)E

UNIVERSITY OF GLASGOW

DEPARTMENT OF GENETICS

POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a Post-doctoral Research Fellow to work with Dr R G Sutcliffe on a three year MRC-supported project that is aimed at the cloning and analysis of the gene for human placental alkaline phosphatase (PLAP). This is a tissue specific member of a presumptive multigene family of alkaline phosphatases, which exhibits a notable degree of polymorphism and is reactivated in certain tumours. In addition, our recent work suggests that PLAP exists in soluble and membrane-associated forms, which are structurally distant.

Prior experience in recombinant DNA methodology is essential.

The starting salary will be within Range 1A of the salary scale for Research and Analogous staff (£8,530 — £9,425 plus superannuation), with an early starting date.

Applications (citing two referees) and enquiries should be to: Roger Sutcliffe, Department of Genetics, University of Glasgow, Glasgow G11 5JS (041-339 8855 ext 7108).

In reply please quote Ref No 5198M. (1211)E

UNIVERSITY OF WARWICK

Applications are invited for the following research posts in the Department of Chemistry and Molecular Sciences:

(a) Postdoctoral Research Fellowship (Physical Chemistry/Physics) To investigate the potential of Langmuir-Blodgett Films, coated on electronic devices, as sensors for chemicals. Applicants should have background in either physical chemistry or physics and should have an interest in both Langmuir-Blodgett films and in solid-state devices. The post is for two years. Initial salary up to £8,530 p.a. on the Research Range IA scale £7,190 — £11,615 p.a.

(b) Postdoctoral Fellowship (Membrane Biochemistry). To study the structure and properties of olfactory sensory membranes. Applicants should have a strong background in membrane biochemistry or enzymes and an interest in receptor proteins. The post is for two years. Initial salary up to £8,080 p.a. on the Research Range IA scale £7,190 — £11,615 p.a.

(c) Research Assistant (Biochemistry). Graduate research associate to study the biochemical aspects of flavour perception. The work will involve both binding studies and chemical modification methods. Applicants should have a good honours degree in biochemistry or biological chemistry. Initial salary up to £7,190 p.a. on the Research Range IB scale £6,310 — £8,530 p.a.

Applicants should state for which post they wish to be considered. Applications (no forms) should include a full curriculum vitae and the names of two referees to Dr G H Dodd, Department of Chemistry and Molecular Sciences, University of Warwick, Coventry CV4 7AL to whom informal enquiries may be made. (tel. 0203-24011-extn. 2234). (1246)E

UNIVERSITY OF KARLSRUHE

POSTDOCTORAL FELLOWSHIP

Applications of molecular biologists are invited to join the bacteriological research group working on bioenergetics of anaerobic respiration. Individuals are expected to have experience in molecular cloning and recombinant DNA techniques. Microbiologists or biochemists with corresponding experience will also be given strong consideration.

The position is available immediately for at least two years, to be renewed after first year. Salary is equivalent to German Government Employees (BAT IIA).

Send application with full cv, research experience, and three references to Prof Dr W Zumft, Lehrstuhl Fuer Mikrobiologie, Universitaet Karlsruhe, Kaiserstr 12, D-7500 Karlsruhe 1, West Germany (Closing Date April 1). (W760)E

MYRON A. BANTRELL POSTDOCTORAL FELLOWSHIPS FOR SCIENTIFIC AND ENGINEERING RESEARCH

The California Institute of Technology, Massachusetts Institute of Technology, and The Weizmann Institute of Science (Israel) will award a number of Bantrell Fellowships for postdoctoral study for the academic year 1984-85, beginning September 1, 1984.

The Fellowship will be granted for one year and will be extended for an additional year upon recommendation of the host institution. In recognition of outstanding academic achievements, the Fellowship may be extended, to those Fellows who have been abroad, for a third year of study in the Fellow's home country (Israeli citizens shall be eligible for such a third year fellowship only at The Weizmann Institute), thus enabling the Fellow to select a position in research or industry.

According to the local practice at the host institution, this Fellowship may include a generous stipend for the Fellow, a travel allowance (one round trip for the Fellow) to the host institution, travel to scientific conferences, and health and life insurance. The program is restricted to citizens of Israel and the United States. US citizens must be less than 30 years of age, and preference will be given to Israeli citizens.

The Bantrell Fellowship Program has been established to offer scientists the best possible opportunity to develop their talents. Fellowships will be granted in the following fields:

California Institute of Technology: Biology, Chemical Catalysis, Earthquake Seismology, Microscience of Materials (Applied Physics), and Theoretical Physics, Astrophysics, and Optical Astronomy.

Massachusetts Institute of Technology: Computer Logic, Energy Conversion, Mechanics of Fluids, Molecular Biology of Higher Organisms, Neurosciences, and Surface Science.

The Weizmann Institute of Science: Chemistry, Life Sciences, Physics, and the Study and Development of National Resources of Israel.

Application and materials in support of any nomination should include a curriculum vitae, bibliography of publications, preprints of manuscripts not yet published, a letter of nomination from the dean or chair in the candidate's university, and two letters of recommendation from faculty who are familiar with the candidate's research. Notification will be mailed by June 30, 1984.

Applications should be sent to the appropriate institution and should arrive by April, 1984. Mail to:

Provost's Office,
California Institute of Technology,
Pasadena, California 91125.

Kenneth A. Smith,
Associate Provost and Vice President for Research,
Massachusetts Institute of Technology,
Cambridge, Massachusetts 02139.

Professor Shmuel Shaltiel,
Dean, Feinberg Graduate School,
The Weizmann Institute of Science,
Rehovot, Israel 76100.

(NW302)E

GRANTS and SCHOLARSHIPS

THE NUFFIELD FOUNDATION

OLIVER BIRD FUND for RESEARCH INTO RHEUMATISM

Applications are invited for research grants for work directed to the better understanding, and treatment, of rheumatic disease. The Oliver Bird Fund, from which over £150,000 was spent on research grants during 1983, is administered by the Trustees of the Nuffield Foundation on the advice of an expert committee whose chairman is Dr D.A.J. Tyrell, CBE, FRC. Grants may be made only for research in UK institutions.

Further details of how to apply are available from the Nuffield Foundation. The closing date for applications is 31st March 1984.

Applications will be considered at a meeting in May, 1984.

The Director
Nuffield Foundation, Nuffield Lodge
Regents's Park, London NW1 4RS

(1230)H

THE ROYAL SOCIETY

Travel and Subsistence Grants from the Parliamentary Grant-in-Aid

Notice is hereby given that the following closing dates will apply in respect of applications for travel and subsistence grants: 1 March, 1 June, 1 October and 1 December 1984. Grants are awarded only in respect of short scientific visits overseas of up to 13 days (generally for Conference attendance), and applications should be submitted on forms to be obtained from the Executive Secretary, (Ref BdeV), The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG, (01-839 5561, ext 222). Grants are only available to scientists of at least PhD status who are ordinarily resident in the UK and are not in the employ of governmental or research council institutions.

For certain major conferences there may be special closing dates and those who may wish to apply should inquire as far in advance as possible, and in requesting forms should indicate the meeting they wish to attend.

Applications in respect of longer term visits overseas can be considered under other schemes administered by the Society, and those wishing to apply should inquire well in advance of travel indicating the approximate duration of the visit, and the country to be visited. (1199)H

CONGRESS

SECOND INTERNATIONAL CONGRESS ON COMPUTERS IN SCIENCE

CALL FOR PAPERS

The Second Conference on Computers in Science, sponsored by Science Magazine, in conjunction with Scherago Associates, will be held in Washington DC. from 28 October – 1 November 1984. The conference will emphasize the use of the workstation for the scientist. There will be invited talks in a number of areas including Biology Workstations, Computer Aided Molecular Design, Workstation Hardware, Artificial Intelligence, Databases, Laboratory Automation and Robotics, and Management of the Electronic Laboratory. In addition there will be submitted poster talks, workshops in a number of areas and a large vendor exhibition. Prospective authors should send for an abstract form, registration and hotel information to Ed Ruffing, Scherago Associates, 1515 Broadway, New York, New York 10036 (212) 730-1050. Completed abstracts should be sent to the conference chairman, Dr. Stephen R. Heller, EPA, PM-218, Washington DC 20460 (202) 382-2424.

Circle No.17 on Reader Service Card.

WORKSHOP

Ninth International Herpesvirus Workshop, August 24-29, 1984
Seattle, Washington

Organizers: Dr Denise Galloway, Fred Hutchinson Cancer Research Center, Seattle: Dr Jack Stevens, University of California, Los Angeles

For information contact: Ms Tamara Moats, Conferences and Institutes, University of Washington DW-50, Seattle, WA 98195 (206) 543 5280. (NW8)V

MISCELLANEOUS

RESEARCH VESSEL FOR ECONOMICAL WORLD WIDE CHARTER

A 55'6" × 19' crabber/seiner design of Ed Monk with a range of 6,000 miles at eight knots. Party of six, experienced crew, extensive electronics including SATNAV.

Spice Island Traders, One Boston Place, Boston, MA 02108 (617) 723-1955. (NW750)J

ACCOMMODATION

AMERICAN going on sabbatical year seeking 2-3 bedroom flat with central heating, washer and dryer for family beginning 1 August, 1984 in Swiss Cottage-Hampstead-Golders Green-Finchley area. Possibility of exchange for 3 bedroom house in Philadelphia suburb (Wynnewood). Contact Prof M M Civan (Physiology Dept, U of Pennsylvania, Richards Bldg/G4, Phila, PA 19104, USA). (NW293)S

ASSISTANTSHIPS

UNIVERSITY OF BRISTOL

DEPARTMENT OF PHYSICS

RESEARCH ASSISTANTSHIPS IN FIBROUS BIOPOLYMER RESEARCH

Applications are invited for thr posts to undertake structural studi in fibrous biopolymers. The resear will be supported by the Agricultur and Food Research Council's Li Group Scheme, on the basis of colaboration between tl University's Physics Department a the Council's Meat Researc Institute. This project is part of ongoing research programn concerned with structure a morphology of fibrous biopolyme using X-ray diffraction, electr microscopy, Fourier transform infr red spectroscopy and biochemi analysis and characterisation.

Prospective candidates shou have a PhD degree and experience biophysics, biochemistry or materi science. The posts are tenat immediately and renewable for up three years. Salary range £8,530 £9,425 pa plus superannuation.

Applications by letter, wi curriculum vitae and the names two referees should be sent Professor E D T Atkins, H H Wi Physics Laboratory, Tynd Avenue, University of Bristol, Brist BS8 1TL, as soon as possible but later than February 29th, 1984. (1214)P

POSITIONS WANTED

APPOINTMENTS WANTE advertise your qualities and qual cations through the most influen science weekly in the world a special reduced cost of *25p a wo* (Personal Box Numbers £1). Advertisements must be pre-paid sent to: Nature Classified (Ap Wtd), 4 Little Essex Street, Lond WC2R 3LF. (890)

nature is keeping ahead. Are you being left behind?

New research results, the very latest international science news, key papers by the world's leading scientists and speed of publication ensure *Nature* remains one of the foremost weekly scientific journals in the world.

But if you're tied in to a circulation list at work, all this vital weekly information will undoubtedly reach you late, often incomplete and sometimes not at all.

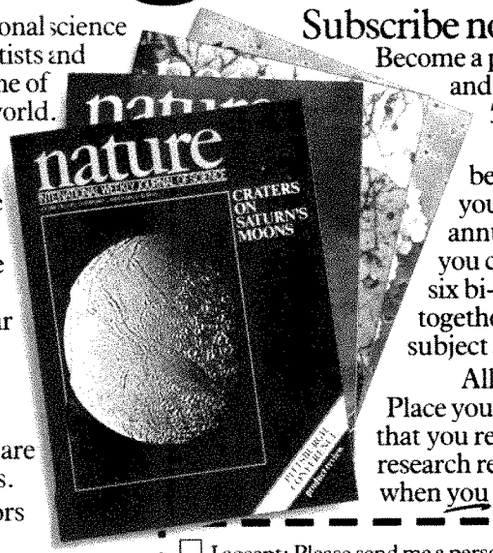
With your own personal copy, you solve the problem. Every week you'll have all the latest research results and science news in your hands within days of publication:

News reports from throughout the world of science and technology.

A **News and Views** section, where new ideas are analysed and discussed by leading researchers.

Articles and Letters in which key investigators disclose their work for the first time.

Book Reviews – Eminent figures offer expert judgments on a wide variety of recent publications.



Special Issues providing an in-depth treatment of topics of importance.

Product Reviews – Detailed descriptions of laboratory equipment newly available.

Classified Advertisements for a wide variety of positions all over the world.

You will no longer be dependent upon other people passing down the 'list' copy, and because you will automatically receive every issue, you won't risk missing a single copy through absence from work. Moreover, you keep all this key information for permanent reference.

Through your door every week

Subscribe now – at Half Price

Become a personal subscriber now and you will receive a discount of 50% off the full rate.

All 51 weekly issues will be delivered to the address of your choice. You can start your annual subscription with any issue you choose. And you will receive six bi-monthly author indexes, together with the annual index of subject and author.

All this for just 94p a week.

Place your order now and make certain that you receive the scientific news and research results crucial to your work when you want them.

☐ I accept: Please send me a personal subscription to *Nature* for one year (51 issues) at the special half-price rate of £49.00.

☐ I enclose my personal cheque for £49.00 made payable to *Nature*. (Note: Institutional cheques cannot be accepted at this special rate).

☐ Please charge to my credit card account.

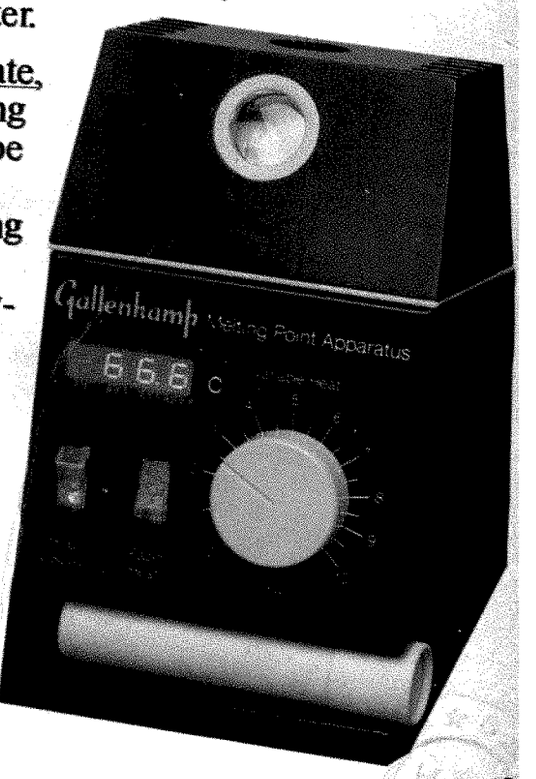
Melts the sample - freezes the reading

It's as easy as that when you use Gallenkamp's new Melting Point Apparatus. Housed in a stylish case it will make melting point determinations easier, quicker and more accurate.



Easier, because the operator can concentrate entirely on the melting sample – no need to keep half an eye on the thermometer.

Quicker, because the platinum resistance sensor responds more quickly to temperature change than a mercury-in-glass thermometer.

More accurate, because the melting temperature can be immediately 'frozen' by pressing the hold button as soon as melting is observed – ordinary mercury-in-glass thermometers can go on rising and errors can be made.

Isn't it time you threw away your old mercury thermometer?

For further details, please write to, or telephone Gallenkamp.

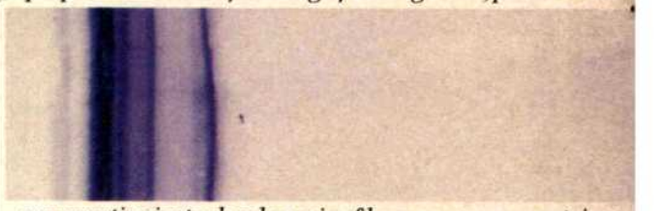
OSTRICHES PRIMITIVE NOT DEGENERATE

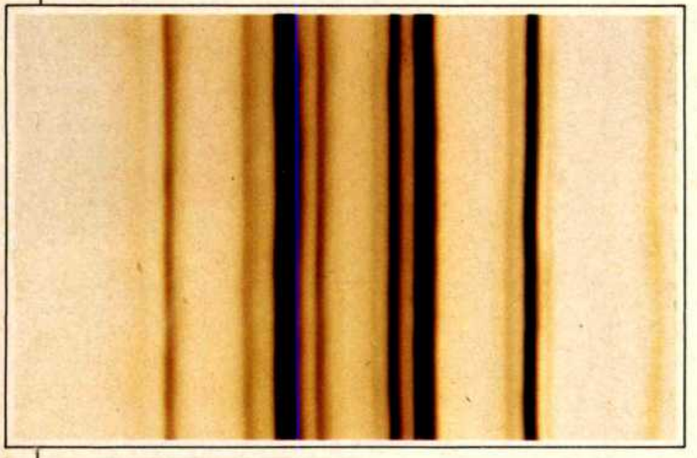
MICROBIOLOGY
product review

Only with the new LKB Horizontal Electrophoresis System do you also get...



A choice of 3 preparative methods

Preparative electrofocusing in Immobiline gels is the newest, most efficient way of separating proteins in quantities up to 1 gram. LKB Immobilines combine greatly improved resolution with sample recovery rates of up to 98%. And the absence of soluble carrier ampholytes means that high resolution preparative electrofocusing of low molecular weight substances is now fully practicable.



Preparative electrofocusing in granular gels is a more traditional method using Ampholine carrier ampholytes, and is also catered for by the LKB Horizontal Electrophoresis System. The enlarged cooling plate of the new Multiphor II doubles the sample capacity, while the movable electrodes give increased flexibility.

– preparative electrofocusing of hemoglobin, pH 6.0–8.5

–preparative isotachophoresis of human serum proteins

Preparative isotachophoresis is the third choice offered by the LKB Horizontal Electrophoresis System, and is a low-cost alternative giving good resolution for separations based on protein mobility. The twin integral buffer reservoirs permit gels to be run either across or along the length of the cooling plate.

◀ *– preparative electrofocusing of hemoglobin using Immobiline, pH 6.5 to 8.5*

This is one in a series of advertisements describing the unrivalled versatility of the LKB Horizontal Electrophoresis System. For further information about preparative methods, and the many other applications of the system, send today for our brochure.

THE LKB SYSTEM

Only LKB can offer the research scientist a complete, integrated system in which each component works with and complements all the others. Based on the new and improved Multiphor II, the system also includes a 5KV power supply, thermostatic circulator, laser densitometer and data evaluation software.

In addition to the instrumentation, LKB provides a range of 18 major kits plus a complete programme of high quality chemicals, supplies and accessories, backed by the full worldwide support of the market leader in electrophoresis and electrofocusing.

LKB – the electrophoresis experts.

DESIGNED FOR A MAJOR ADVANCE IN PEPTIDE SYNTHESIS

THE CRB PEPSYNTHESISER

The first peptide synthesiser incorporating the simplicity and high efficiency of the 'Fmoc-POLYAMIDE' solid phase method with the speed, economy and ease of operation of a CONTINUOUS FLOW SYSTEM.

- Low cost
- Exceptionally mild reaction conditions
- High product yield
- Simple, rapid procedure
- Continuous UV monitoring of reaction progress
- High product purity

The Fmoc-Polyamide Method as developed by Dr. R.C. Sheppard and his group replaces the customary polystyrene resin with a polar polyamide resin. This resin is freely permeated by polar solvents such as dimethylformamide which is a particularly good reaction medium for peptide synthesis. The use of Fmoc amino acids and t-butyl protecting groups avoids the repetitive and vigorous acid treatments required in conventional synthesis and considerably reduces the accumulation of byproducts.

The Continuous Flow System for removal of excess reactants through a column is inherently more efficient than batchwise washing which is used in conventional peptide synthesisers. our continuous flow system has been designed especially for use with 'PEPSYN K'. This polyamide resin is held within the pores of an inert inorganic support which allows the rapid diffusion of reactants without generation of high back pressure.

The Continuous UV Monitoring of both the amino acid addition and the deprotection steps provides reassuring evidence that the synthesis is proceeding normally.

Pepsyn Reagents are provided as a complete range of high purity products prepared specially to ensure maximum success with the versatile Fmoc-Polyamide method. They include Fmoc amino acids and derivatised resins for the synthesis of free peptides, peptide amides and side chain protected peptides.

Technical Support is based on highly successful and extensive use of the Fmoc-Polyamide method in our own laboratories.

Now safe for laboratory use!
WORTHINGTON
PURIFIED RICIN-A CHAIN
for targeted cytotoxicity

GREATLY REDUCED TOXICITY

- Free of B chain mediator of cell entry
- 10,000 times less toxic to whole cells than complete Ricin
- Non-toxic laboratory handling

SUITABLE FOR THERAPEUTIC PRODUCT DEVELOPMENT

- Highly purified for use in whole animal injection studies
- Can be conjugated to monoclonal antibodies, hormones or other ligands to target cytotoxic effect
- Projected human LD_{50} of 1 to 3 grams based on animal studies

STABLE FOR LABORATORY USE

- Shipped in solution
- Remains soluble while stored frozen

NOW EVEN MORE EFFECTIVE WITH THE INTRODUCTION OF RICIN-B CHAIN (THE NATURAL MEDIATOR OF RICIN-A CELL ENTRY)

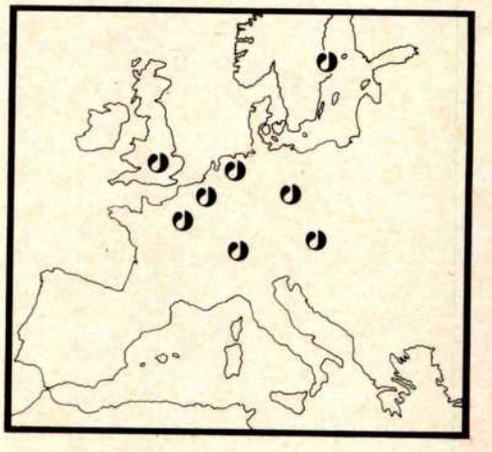
Now order your research biochemicals...

As a result of the recent merger with P-L Biochemicals, Pharmacia Fine Chemicals are now able to bring you a wide range of over 2,200 high quality products for molecular biology and biochemical research.

And all you have to do to order any of our speciality biochemicals is to contact your local Pharmacia office who are holding large stocks ready for



faster than you can say oligodeoxynucleotides

immediate delivery.

We will ensure a fast delivery at quality which you expect when you order from Pharmacia.

So while you are trying to say Oligodeoxynucleotides, remember...we are only a telephone call away.

Send for your free Pharmacia P-L Biochemicals Catalogue now.

Mycoplasma Detection and Identification

Can You Really Afford to Wait?

In five days, you can know whether mycoplasmas are infecting your cells. In five hours, you can know which kind.
BRL introduces MYCOTECT™ and MYCOSPEC™.

Detecting mycoplasmas was always a lengthy, tedious and expensive procedure. Therefore, most laboratories tested cell lines only when they looked infected. By that time, the infection frequently had already spread to other cells.

Determining the mycoplasma species is an important step in tracking down its source and preventing future infections. Until now, however, the process was too long, complicated and expensive to be practical.

BRL has changed all that.

With MYCOTECT and MYCOSPEC, available *exclusively* from BRL, you can detect and identify mycoplasmas easily and inexpensively, right in your laboratory.

MYCOTECT

MYCOTECT is cytotoxic to mycoplasma-infected cells. After incubation of cell samples with MYCOTECT and exposure to crystal violet, cell monolayers in uninfected wells stain more intensely, and therefore can be easily distinguished from the sparse cell layers found in mycoplasma-infected wells. The entire process takes only five days -less than one fifth the time needed for detection by conventional methods. The cost of a MYCOTECT assay is only a fraction of the cost of current tests, and the only equipment needed is a 24-well plate.

MYCOSPEC

MYCOSPEC is a rapid, simple and inexpensive assay for the five major mycoplasma species that account for more than 95% of all laboratory mycoplasma infections. Mycoplasma samples are incubated separately with monoclonal antibodies to each of the five species, then

with a biotinylated secondary antibody and finally with a streptavidin-horseradish peroxidase complex. The sample that stains when diaminobenzidine is added contains the monoclonal to the infecting species. With MYCOSPEC, identification is complete within five hours.

MYCOTECT and MYCOSPEC. Only from BRL. Now you don't have to wait.

NATURE VOL 307 23 FEBRUARY 1984

COVER

The tarsal region in flightless birds develops quite differently from that in flying birds like the quail shown on the cover, and has a structure similar to that found in theropod dinosaurs. This suggests that flightless birds have arisen from an independent ancestral stock and are not derived from flying birds (see p.733).

Nature (ISSN 0028-0836) is published weekly on Thursday, except the last week in December, by Macmillan Journals Ltd and includes the Annual Index (mailed in February). Annual subscription for USA and Canada US $230 (for subscription prices elsewhere, see next page). USA and Canadian orders only to: *Nature*, Subscription Dept PO Box 1018, Manasquan, New Jersey 08736, USA. All other orders to *Nature*, Brunel Road Basingstoke, Hants RG21 2XS, UK. Second class postage paid at New York, NY10010 and additional mailing offices. US Postmaster send form for 3579 to: *Nature*, 15 East 26 Street, New York, NY 10010. Published in Japan by Macmillan Shuppan K.K., 5th Floor Eikow Building, 1-10-9 Hongo, Bunkyo-ku, Tokyo, Japan. 1984 Macmillan Journals Ltd.

New ligands

- Affinity labelling reagent for oestrogen receptors
  [*ring*-^{3}H]Tamoxifen aziridine — TRK.788
- Calcium channel blocker
  (+)-[*methyl*-^{3}H]PN 200–110 — TRK.787
- Selective ligand for opiate receptor
  [*tyrosyl*-3,5(n)-^{3}H]Dynorphin (1-9) — TRK.795
- Muscarinic agonist
  [*N-methyl*-^{3}H]Oxotremorine M acetate — TRK.794
- Dopamine agonist
  [^{3}H]5,6-DPAT — TRK.792
- Selective α_2 antagonist
  [^{3}H]RX 781094* — TRK.799
- Exclusive adenosine agonist
  (−)-[^{125}I]HPIA — IM.153
- Receptor grade [^{125}I]insulin, human
  [^{125}I]-(A14)-monoiodinated human insulin — IM.166
  [^{125}I]-(B26)-monoiodinated human insulin — IM.167

Next week in *Nature*:

- What economists can tell governments
- The effects of nuclear war
- Laboratory model of Jupiter's Red Spot
- Polar glaciation and ice ages
- Insight in pigeons
- Benzodiazepines and postsynaptic GABA sensitivity
- Homology of human T-cell leukaemia virus envelope
- Cryo-electron microscopy of viruses
- Transepithelial transport of immunoglobulins
- H.N.V. Temperley reviews S.J. Brams's *Superior Beings: If They Exist, How Would We Know*

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

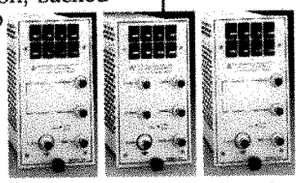
Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

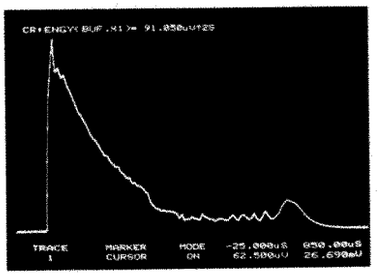


We Make Transients Talk.

Transient analysis is a complex job: capture, digitizing, storage, display, analysis and data transfer. It's harder still if you need remote control capability. Most general purpose instruments can't handle more than one or two of these steps. But the Data 6000 Universal Waveform Analyzer does them all...with speed and power you won't find in any other single instrument. In fact, the Data 6000 offers more powerful capabilities than you could obtain from an entire roomful of equipment at many times the cost. Nothing else even comes close to the Data 6000, which offers you:

Faster Data Acquisition

No matter how short-lived the event, you'll capture it with high resolution, thanks to the Data 6000 100 kHz and 100 MHz digitizing modules. Sample times as short as 10 nanoseconds, with full 8-bit resolution, give you the accuracy you need. Only Data Precision, backed by Analogic's leadership in A/D conversion and data acquisition could have offered the Data 6000's powerful acquisition capabilities.



And that's only the front end of the Data 6000's power.

Model 610 2ch 100KHz | Model 611 4ch 100KHz | Model 620 2ch 100MHz

Quicker on the Trigger

Trigger level may be set with minimum 8-bit precision, to eliminate false triggering on noisy signals without sacrificing sensitivity. And event display can begin precisely at the moment you select. View pre- and post-trigger events up to 100% of selected time-base away from the moment of triggering...from milliseconds to months before *and* after. You'll never miss a shot with the Data 6000's smart trigger.

Compute and display a wide variety of functions from the captured signal. Useful functions for transient analysis are Rise, Fall, Settling, and Display Times; Overshoot, Maximum, Minimum, Peak to Peak, Area or Energy under the curve; Real and Complex Magnitude Spectra; Real and Complex Log Magnitude Spectra; and many more...all available with a single keystroke!

More Digital Storage

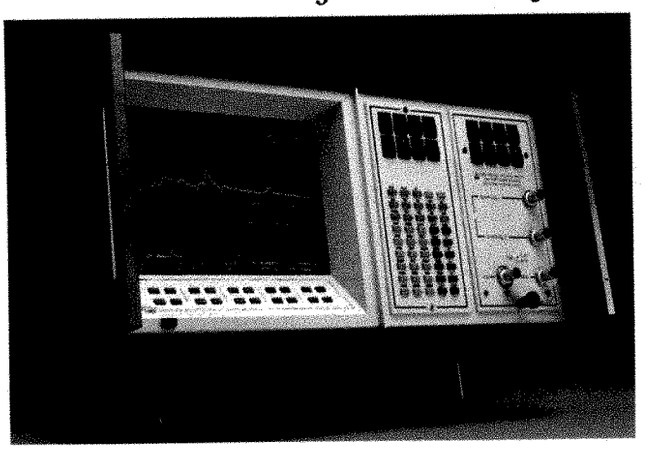
Up to 56,000 points of data may be stored in on-board storage memory, with unlimited expansion available on accessory floppy disk or your mass storage media. Data acquisition memory holds up to 56,000 points per channel (with the 610 and 611 plug-ins; 16,000 points for the 620).

And data storage is accurate, supporting full 5-decimal place readouts. Double precision accumulators are standard. The high resolution CRT display lets you view waveforms as accurately as they are stored, and a comfortable screen angle permits easy use. The large display has full alphanumerics for on-screen labelling and documentation of functions.

On-Board M68000

How does the Data 6000 do so much more than an ordinary A/D converter, digital waveform recorder, digital storage oscilloscope, and engineering microcomputer? The answer is inside: a fast, powerful M68000 microprocessor, armed with the fastest Fast Fourier Transform Algorithm, and capable of quick, user-friendly communications and remarkable computational power. And when you need to go beyond the Data 6000's stand-alone capabilities, versatile data transfer is available through the RS-232 port. And IEEE-488 bus compatibility allows full integration of the Data 6000 with your system.

IEEE-488



Superior. Demonstrably Superior.

The Data 6000's unique capabilities with transient waveforms are reason enough to have it on your bench. But if you need further reasons, the Data 6000 has them. An instrument this powerful can do much more than transient analysis. Consider it as:

- ☐ A Storage Oscilloscope
- ☐ A Spectrum Analyzer
- ☐ An Auto/Cross Correlator
- ☐ A Transient Recorder
- ☐ An RF or Audio Signal Analyzer
- ☐ An ATE Subsystem
- ☐ A Vibration Analyzer

For transient analysis with unprecedented ease, and much more, try the Data 6000. For further information, call:
800-343-8150
Or in Massachusetts, 800-892-0528.

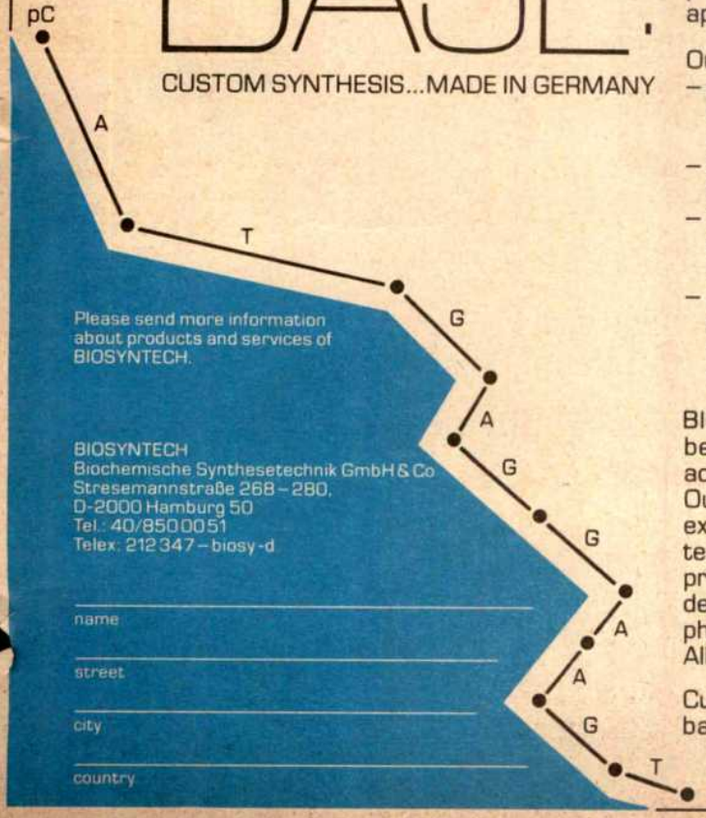
Code-Breakers and Code-Makers BIOSYNTECH

OUR BUSINESS IS YOUR BASE.



CUSTOM SYNTHESIS...MADE IN GERMANY

BIOSYNTECH is the first company in Western Germany which has an experienced and professional team to support your genetic engineering programmes in either research or industrial application.

Our main product lines
- Custom synthesis of primers and probes (mixed probes) including the incorporation of modified bases.
- Synthesis of linker/adapter molecules also following your individual requirements.
- Total or partial synthesis of structural genes and regulatory DNA sequences (signal structures).
- Design and development of genetic engineered microorganisms for the production of proteins useful for medicine, pharmacy and agriculture.

BIOSYNTECH guarantees all DNA fragments to be of highest purity available. Every shipment is accompanied by a purity certificate.
Our "contract discount" programme offers you exceptionally favourable conditions for long term cooperation. Modern technology and a professional team imply a quick delivery of the desired sequences. You simply order by telephone or telex thus saving time and costs.
All orders will be handled in strictest confidence.

Custom synthesis is our business, and your base.

Please send more information about products and services of BIOSYNTECH.

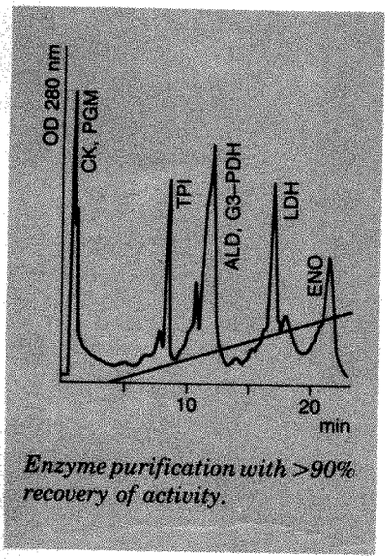
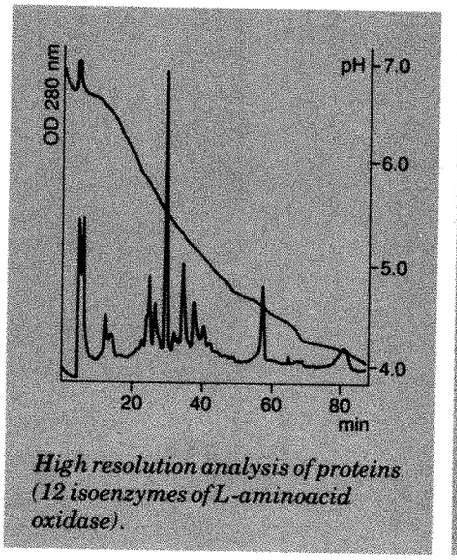
FPLC means ...

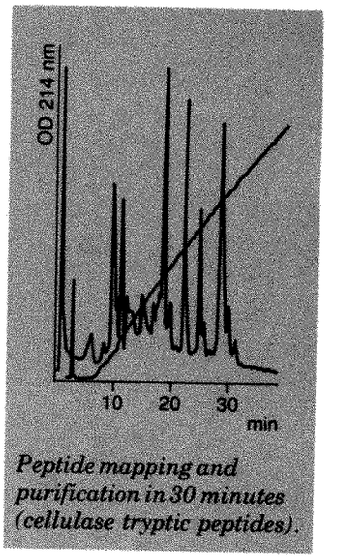


Separation power



Fast Protein/Peptide/Polynucleotide Liquid Chromatography – but speed is not its only virtue.

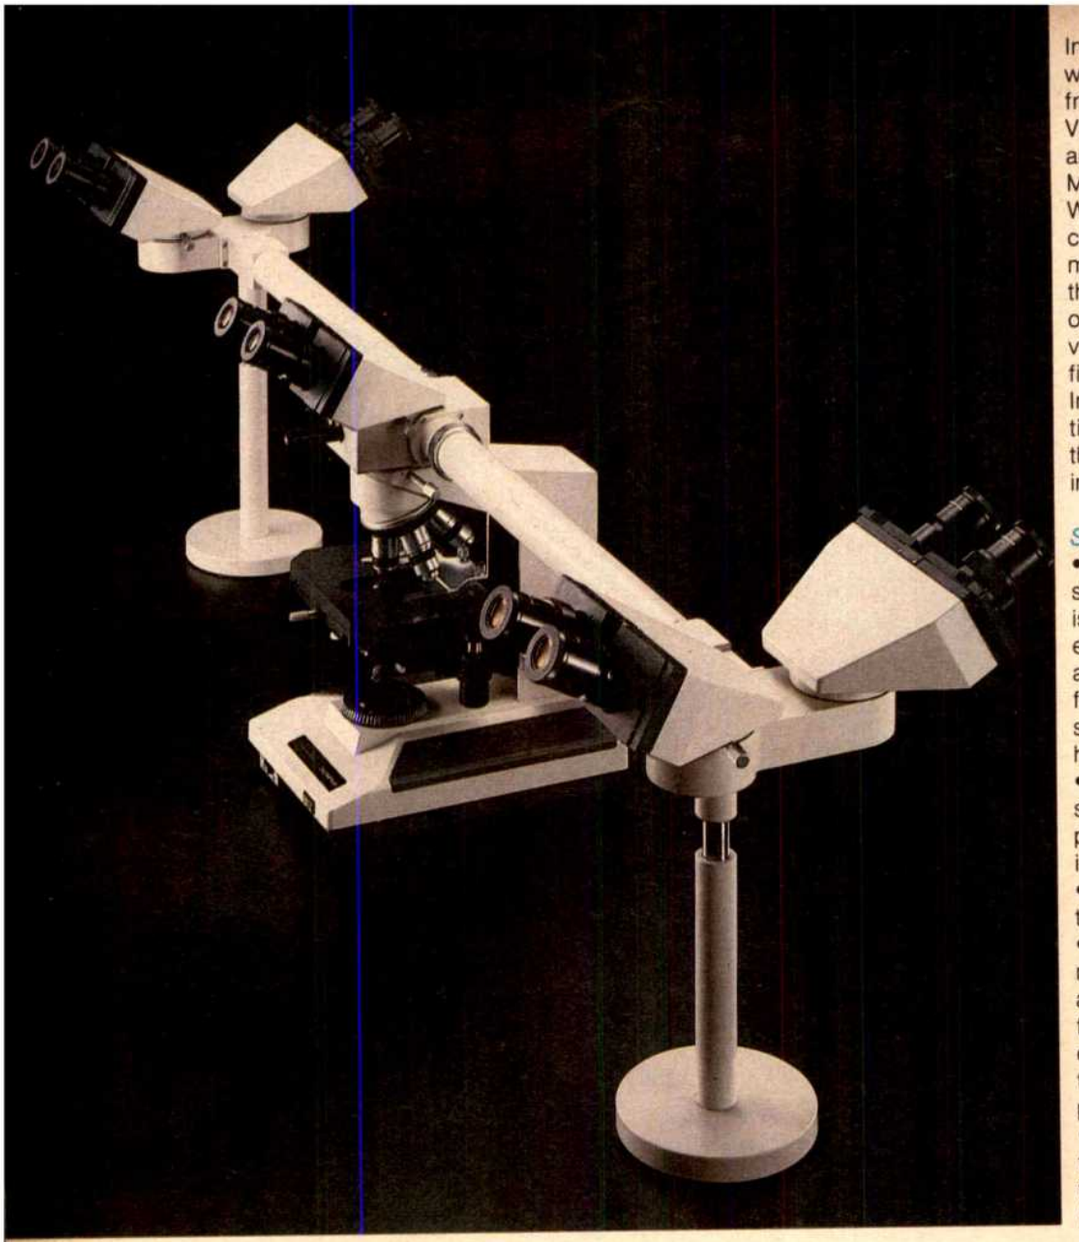
FPLC means new unique, hydrophilic, monodisperse media providing high performance resolution and high recovery of biological activity: and new silica based media providing high performance resolution, superior yields of proteins, peptides and polynucleotides – with sample sizes up to 100 mg.



FPLC means new instruments, new media and methods – the combination of which is a high performance liquid chromatography system providing a degree of resolution, capacity and speed previously unattainable for purifying proteins, peptides and polynucleotides.

Enzyme purification with >90% recovery of activity.

High resolution analysis of proteins (12 isoenzymes of L-aminoacid oxidase).



Peptide mapping and purification in 30 minutes (cellulase tryptic peptides).

For further information about the separation power of the FPLC System, please contact your local representative of Pharmacia Fine Chemicals.

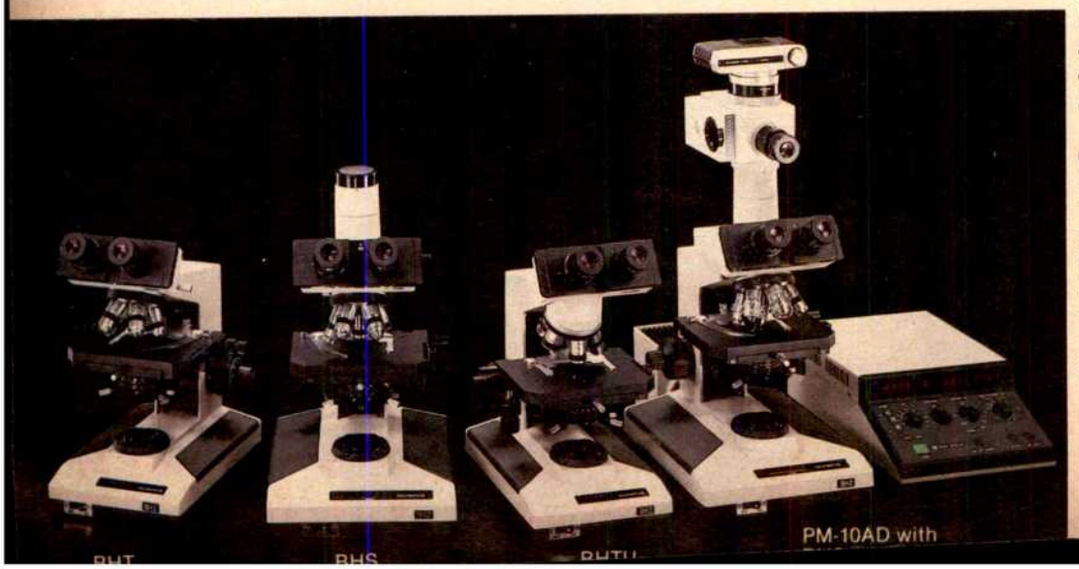
Pharmacia Fine Chemicals

Circle No.52 on Reader Service Card.

In response to an increasing demand worldwide for a multi-head microscope from Olympus, the BH2-MDO Multi-Viewing Attachment is now available as an accessory of the BH-2 System Microscope.

With the BH2-MDO, up to five observers can view and study the same specimen at the same time. Not only does this provide better efficiency in medical or scientific studies, but it is also highly valuable in educational and industrial fields.



Indeed, microscope users in all scientific and technological areas will find the BH2-MDO an important new tool for instruction, consultation and training.

Special Features:

- All five viewers see the image in the same orientation. Magnification factor is 1x. The field of view is the same for each observer. A unique feature of this attachment, this is particularly useful for instructors and students and represents a major advance over what has hitherto been available.
- Thanks to superior optics and a special coating, every observation tube provides the same uniformly bright image.
- Phase contrast observation is consistently bright up to 40x magnification.
- As with our dual observation attachment, a moveable illuminated pointer appears either green or yellow in the field of view to provide maximum contrast with the specimen stain so the area under discussion can be pointed out easily and clearly.
- The distance between the observation tubes is such that viewers can observe the specimen comfortably, without interfering with each other.

AN ADVANCE IN SCIENTIFIC ACHIEVEMENT

The BH2-MDO–Now, five persons can view simultaneously

The BH2-MDO Multi-viewing Attachment is an advance in scientific achievement—an advance that means greater efficiency.

Why S&S goes to such lengths in a minicolumn.

S&S doesn't take any shortcuts with the Elutip™-d.

For DNA purification, the Elutip-d optimizes both sample recovery and time savings. More effort goes into manufacturing this reliable, efficient minicolumn. And that's why more researchers rely on it.

There's no reason to sacrifice sample recovery for speed. The flow rate of the Elutip-d column ensures maximum recovery of DNA. The ideal combination of particle sizes in the Elutip-d matrix maximizes the adsorption of sample. Elutip-d easily fits any Luer-lock syringe, thus saving time by allowing samples to be pushed through during elution, eliminating time-consuming gravity flow. No special pipetters are needed.

Then, there's greater capacity—up to 100 µg of DNA. In fact, it's 2½ times the capacity of the closest competitor—more than enough for any test. The Elutip-d adds security to your sample recovery no matter how small your sample.

Ask for the "original" DNA purification minicolumn for more time savings and assurance with valuable samples. S&S puts more into Elutip-d, so you get more out of it.

Contact S&S for more information on the Elutip-d column and to receive your copy of the latest issue of the S&S Elutip "Tips for Recovery"—*Recovery of DNA from Low Gel Temperature Agarose.*

A Dream Becomes Reality....

Colorimetric DNA Probe Detection of Pathogens

Visualization of Herpes virus using an Enzo Patho-Gene™ Kit.

Introducing....

Enzo Patho-Gene™ Kits

For detection of HSV I & II, CMV, EBV, HBV, and Adenovirus.

For years researchers have sought a means for recognition of unique genes as the ultimate method of pathogen identification.

Now, for the first time, this dream is realized. The direct detection of specific viral DNAs can be quickly and safely carried out with Enzo Biochem's Patho-Gene™ Kits, the newest additions to The Enzo Bio-Probe™ System. Currently, kits are available for the identification of Herpes Simplex Virus I and II, Cytomegalovirus, Epstein Barr Virus, Hepatitis B Virus, and Adenovirus 2.

Patho-Gene™ Kit detection is based on DNA hybridization and visualization of hybridized probe DNA by color producing enzymes. The viral DNA probe is tagged with biotin a safe, stable reporter molecule. Upon hybridization to viral target DNA, detection is accomplished using Enzo's streptavidin-horseradish peroxidase detection complex.

The kit provides ready to use biotinylated probe DNA and enzymatic detection complex.

Enzo Patho-Gene™ Kits are for research purposes only.

Herpes Simplex Virus I and II Patho-Gene™ Kit	EBP-HSV-855
Cytomegalovirus Patho-Gene™ Kit	EBP-CMV-852
Hepatitis B Virus Patho-Gene™ Kit	EBP-HBV-853

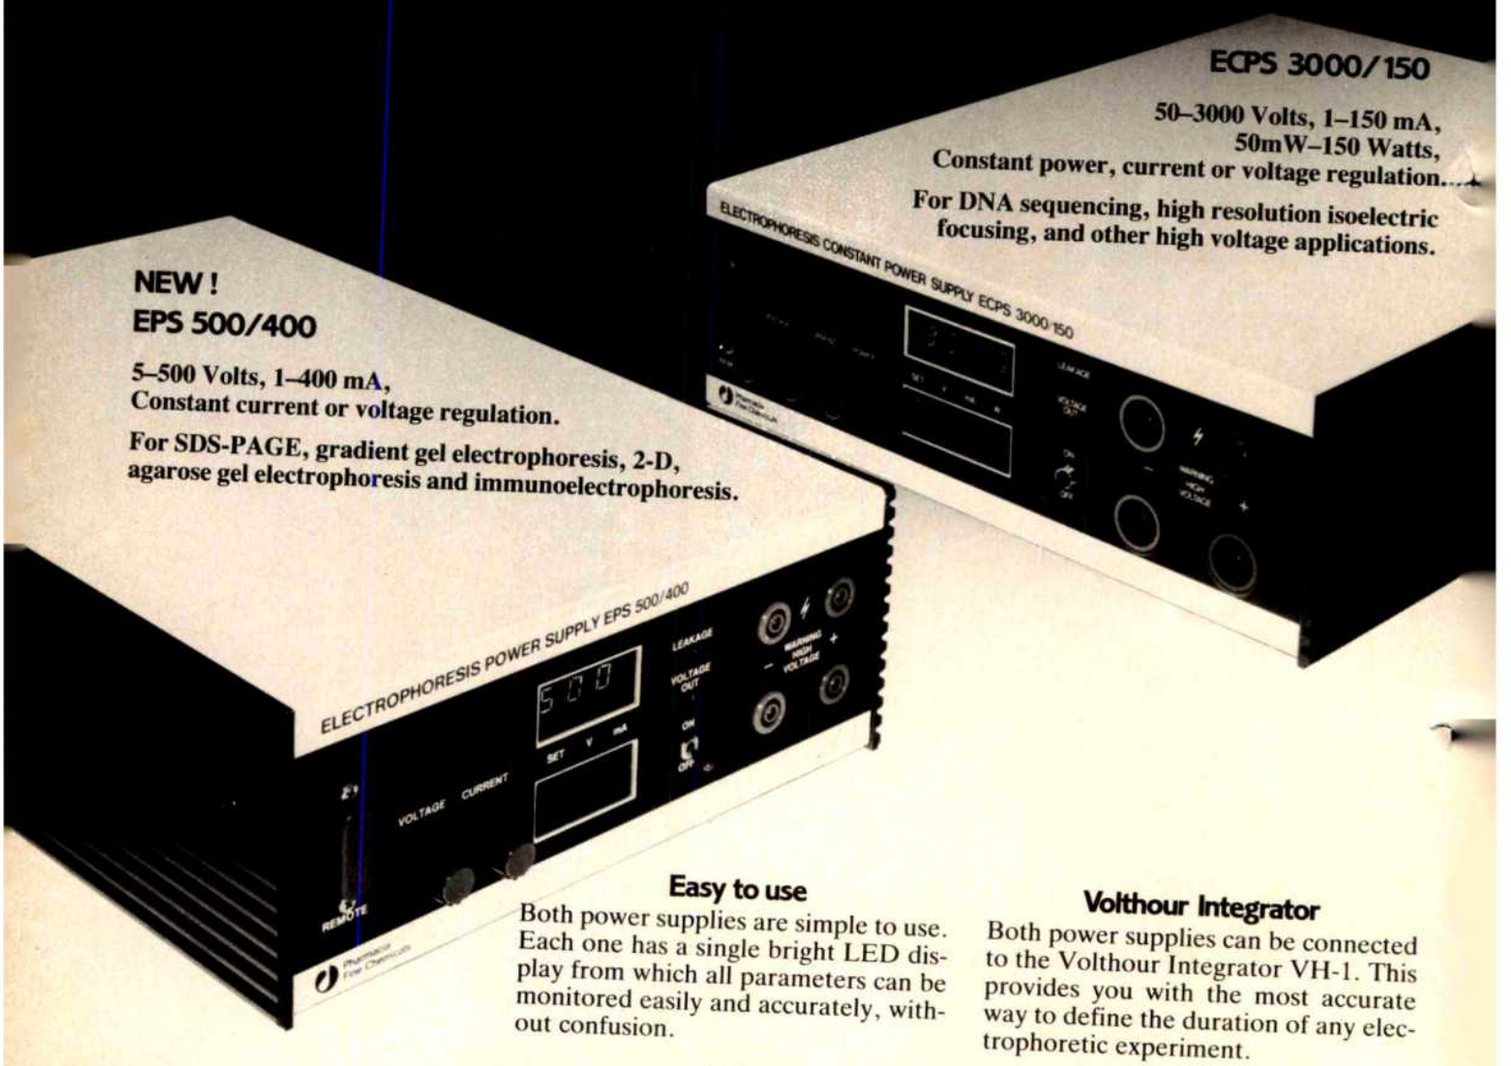
From Pharmacia
Two Power Supplies
500 Volts and 3000 Volts

for all your gel electrophoresis needs

ECPS 3000/150



50–3000 Volts, 1–150 mA,
50mW–150 Watts,
Constant power, current or voltage regulation.

For DNA sequencing, high resolution isoelectric focusing, and other high voltage applications.

NEW !
EPS 500/400

5–500 Volts, 1–400 mA,
Constant current or voltage regulation.

For SDS-PAGE, gradient gel electrophoresis, 2-D, agarose gel electrophoresis and immunoelectrophoresis.

Easy to use

Both power supplies are simple to use. Each one has a single bright LED display from which all parameters can be monitored easily and accurately, without confusion.

Safe

When working at high voltages, operator safety is of prime concern. Both power supplies incorporate inbuilt safety features which include a ground leakage circuit, and a unique load fault detector.

Volthour Integrator

Both power supplies can be connected to the Volthour Integrator VH-1. This provides you with the most accurate way to define the duration of any electrophoretic experiment.

For further information on the Pharmacia Power Supplies and the VH-1 contact your local Pharmacia representative.

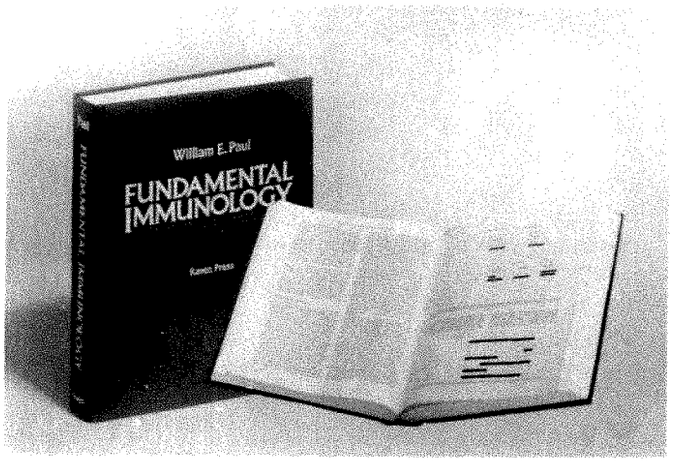
The definitive textbook of basic immunology... a landmark contribution....



PAUL'S FUNDAMENTAL IMMUNOLOGY

Edited by
William E. Paul, M.D.
Chief, Laboratory
of Immunology
National Institutes
of Health
National Institute of
Allergy and Infectious
Diseases
Bethesda, Maryland /
U.S.A.

The unprecedented growth of the field of immunology has created a need for a definitive fundamental text—a source that can serve as a complete introduction for the student and a detailed, sophisticated reference for the researcher. FUNDAMENTAL IMMUNOLOGY is the first book available to meet this need. Under Dr. Paul's superb editorial direction, a roster of experts sets forth the key concepts of contemporary immunology.

The book begins with a coherent discussion of the organization of the immune system and the history of immunology. Building on this framework, the text offers thorough coverage of:

- cells of the immune system
- antibodies and receptors
- immunogenetics
- regulation of the immune response
- effector mechanisms of immunity

Reflecting the contributions of modern genetics and cell biology, the authors describe such methods as hybridomas and monoclonal antibodies, cellular identification and separation, and long-term culture of immunocompetent cells.

No other source provides such intensive coverage of the basic issues of modern immunology. Whether you're a newcomer to this exciting discipline or a researcher seeking an up-to-date refresher, this landmark text is a book you will find indispensable.

1984 / 880 pp. / 206 illus. / 165 tables / $80.00
Order Code 1307

INTRODUCING

Centricon™

THE INGENIOUS NEW DISPOSABLE MICROCONCENTRATOR

1. Fast

Pipette your 1-2ml sample into the top reservoir and spin in a centrifuge. That concentrates the sample down to 25-40µl in less than one hour—with no danger of spinning to dryness.

2. Simple

Then invert the top half and spin again briefly. That brings your retentate out where you want it—perfectly accessible in the cone-shaped cup.

3. Efficient

You get high recovery. Desalting or buffer exchange is performed in the same Centricon simultaneously with concentration. And all with no special equipment, no awkward procedures, no cleanup. Centricon is disposable.

Centricon is ideal for concentrating small biological samples containing proteins, peptides, nucleic acids, viruses, bacteria, and other macromolecular solutions. Send for the complete story on this unique new timesaver. Or call Technical Service: 800-343-1397.

Patent Pending

amicon

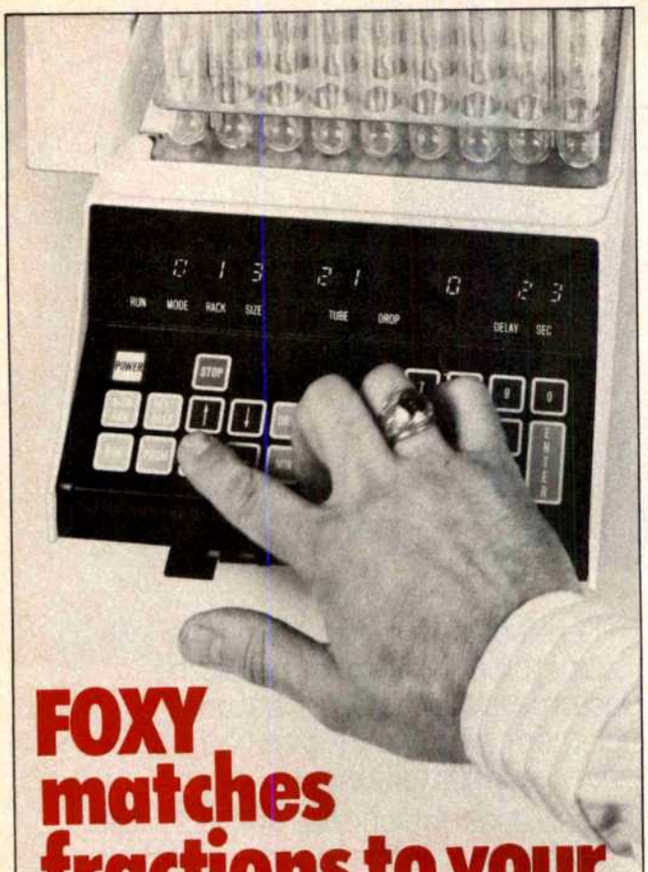
Scientific Systems Division Cherry Hill Drive. Danvers, MA 01923
To order call: 800-343-0696 (In MA and international:617-777-4550)

Visit AMICON at ASM Booth 126-128 and FASEB Booth A42-A46.

Sometimes a good idea begins with a product or service you didn't know about. That's where our technical representatives can help.

There's always a possibility that something you're doing could be accomplished faster, or better, or more efficiently if you had the needed information.

Often enough your NEN representative has that information—whether it be a new method, a better product, or one of NEN's extra services.



Just ask. The answer will come from solid training and experience. More detailed technical answers are quickly available, too. Our representative will see that the question is handled by the most appropriate of several sources at NEN, such as our Technical Services Group, who specialize in customer assistance.

But first talk with the person who represents it all. A good idea may be only a conversation away.

FOXY matches fractions to your chromatogram.

Not to the clock.

Program your collection by absorbance peaks, retention times, timed intervals, counted drops, or pumped volumes. You can even enter fraction size directly in ml if you have an ISCO WIZ peristaltic pump. FOXY rejects void volumes, locates and saves desired peaks, controls valves and pumps to make gradients or automate your system, and changes racks and volumes according to peaks or time. For HPLC, collect successive injections without resetting, and overlay repeated injections of the same sample to collect identical peaks in the same tubes. The sloped keyboard, 12-digit display, and logical programming make it all easy to do.

FOXY takes practically any size test tube, plus 28 mm scintillation vials and even 500 mm bottles. It holds up to four columns and 288 tubes on just a narrow slice of your bench. The most capable fraction collector ever made costs less than you'd think. For a complete catalog, write: ISCO, Box 5347, Lincoln, NE 68505, U.S.A.

See us in booths 9017-10018 at Pittsburgh Conference

RATS!!!
CARDIAC OUTPUT BY THERMODILUTION

"CARDIOMAX-II-R" is the only computer which can measure cardiac output of rats (also guinea pigs, rabbits, dogs, chickens, horses and humans). For rats, it uses unique Columbus Instruments thermodilution microprobes **1/3 mm in size!** It also measures systolic, diastolic and mean blood pressures and heart rate up to 1000 beats per minute. Stroke volume is also automatically computed.

Why Measure Cardiac Output of Rats?

Development of salt sensitive and salt resistive strains of rats provided inexpensive models for studying hypertension. Dynamics of rat circulatory system is similar to dogs or humans. Studies on rats cost only a fraction of studies using dogs.

Automatic Measurements Without Supervision

All parameters (cardiac output, stroke volume, three blood pressures, blood temperature, heart rate, time of day) can automatically be measured periodically and printed when using **"Cardiomax-II-R"** with Columbus Instruments Automatic Injector and Printer.

For more information, call or write to:

O_2-consumption
CO_2-production
Respiration Rate

Simultaneously measured in 1 to 8 animal cages

FEATURES

• One controller for 1 to 8 animal cages • Continuous measurement of O_2, CO_2 and Respiration Rate over a 24 hour period in ml/kg of body weight/hour in STP units. • Printer prints results every four (4) minutes for each of 1 to 8 animals as well as oxygen percent level in each animal cage • System adaptable to small or large animals • Continuous airflow through system with oxygen level measurements at the output and input • High accuracy, >98% of full measuring range e.g. typical error ±30 ml oxygen/kg/hour in 3000 ml oxygen/kg/hour range • User adjustable alarm warns user of possible hypoxia • Reuseable absorbants • Auto reference assures high accuracy, system periodically measures ambient air and corrects itself • Optional RS-232 interface for communication with other computers • Insensitive to temperature variations in the animal cage.

Columbus Instruments also supplies monitors for: Animal Activity, Cardiac Output, Drinking and Feeding, Respiration Rate and Startle Response.

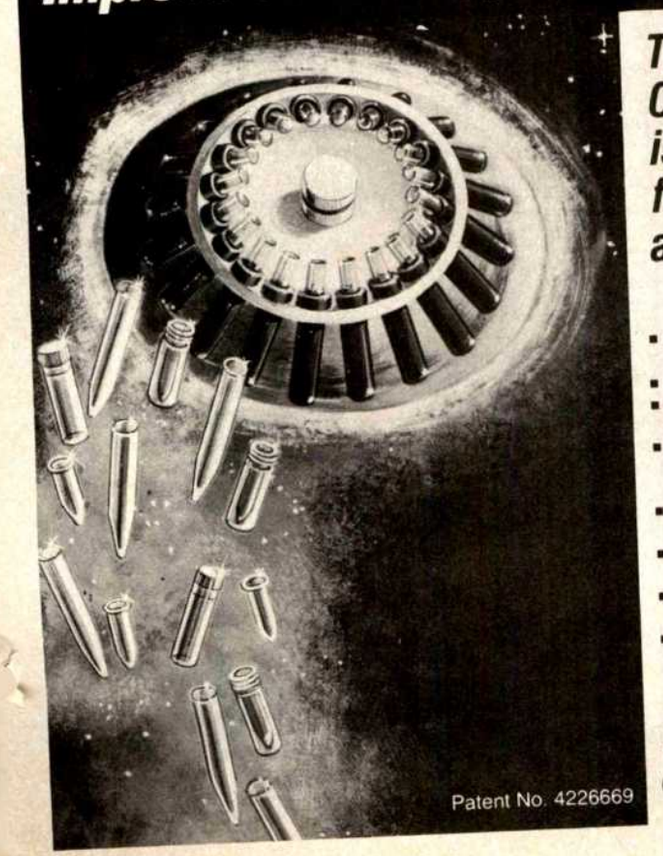
GIVE YOUR T-CELLS ONE TO GROW ON.

Our Human T-Cell Growth Factor (Interleukin-2) makes the best sense of all when you want to achieve active, longterm proliferating growth of T-lymphocytes every time.

It's prepared from large pools of human macrophage-depleted lymphocytes stimulated by PHA. And its activity is enhanced by using active macrophages and by the intensity of the mixed lymphocyte reaction.

We offer three TCGF preparations. Crude. 10X Crude. And Lectin-Free. Each can be relied upon to produce quickly growing T-Cell populations every time.



Call us toll free to place a trial order. Or ask for our free brochure.

Improve Your Assays in Any Biochemical Procedure!

The Savant "NO BUMP" Speed Vac Concentrator/Evaporator is now standard procedure for the following and many other applications.

Achieve 100% Sample Recovery!

- **HPLC** sample preparation where a dried, concentrated sample is important.
- **GLC** sample preparation . . . as above.
- **DNA** sequencing — evaporation of piperdine.
- **PHOSPHOLIPID** separation by HPLC — total evaporation of Acetonitrile-Water Solvent.
- **TRIETHANOL AMINE** carbonate evaporation.
- **SOMATOSTATIN** concentration by evaporation of acetic acid.
- **INTERFERON** purification by dialysis and evaporation of solvent phase.
- **TRI-CYCLIC** anti-depressant drug blood levels measured after a series of extractions and evaporations to dryness.
- **NEUROTRANSMITTERS** such as Acetylcholine, Dopa, etc. Now include the Speed Vac Concentrator for the essential evaporation step.
- **AMINO ACID** and Peptide analysis.
- **SUBSTANCE P** concentration and assay.
- **HORMONE** and Enzyme assays.
- **TISSUE EXTRACTS** and Column eluates concentrated by "NO BUMP" solvent removal.
- **ELECTROPHORESIS AND CHROMATOGRAPHY** is greatly improved by concentration prior to application of sample to the support medium.

NATURE'S BIOREACTOR

The New Bio-Response MCT* (Mass Culturing Technique) System Delivers Monoclonal Antibodies And Other Mammalian Cell Products When You Need Them—From Grams To Kilograms.

Insufficient quantities of desired peptides are a key cause of expensive research and production delays. The MCT system is a *new* and *unique* mammalian cell culturing process designed to overcome the obstacle of insufficient quantities of peptides by delivering the quantity you need...*when you need it!* Additionally, every step in MCT production has been developed to contain costs now and in the future while maintaining exceptional purity and quality in mammalian cell proteins.

Quantity

Unlike conventional cell-culture methods, the MCT system uses "fresh," free-flowing lymph directly from a cow. Following treatment, the lymph is continuously diffused into and out of a growth chamber. This nearly *in vivo* growth environment stimulates continuous and optimal protein secretion. The result? Large quantities of desired proteins enabling you to move to the clinic or market...*faster.*

Cost

Unlike conventional cell-culture methods that require extensive labor forces and expensive growth mediums, Bio-Response's MCT is a closed, steady-state system. In essence, the MCT system starts with a low-cost lifeline—a feeding cow—and ends with a pure, quality product. MCT ...*an optimal system at low cost.*

Purity

Unlike conventional cell-culture methods, the MCT system is designed to insure purity without tedious processing. By directing the lymph across semi-permeable membranes, MCT provides both separation of media protein from desired cell products, and a continuous nutrient flow. The ability to add or withdraw from the chamber to maintain optimal cell density permits continuous harvest of a highly pure product.

Quality

Unlike conventional methods of production that attempt to create biologically active mammalian cell products, the MCT system provides a pure-mammalian product—an exact copy of the original protein and, in the case of non-antibody polypeptides, uncompromised by inappropriate glycosylation and disulfide bond formation. There is a growing consensus favoring products produced in a mammalian cell-culture system, such as the Bio-Response MCT system.

Peptide Soup.

Peptide Soup. That's all you'll get if you use inferior bioactive peptides in your research.

Avoid costly, time-consuming, and embarrassing errors by using quality bioactive peptides from Vega Biotechnologies, Inc.

Vega's peptides are subjected to multiple testing — HPLC, TLC, Amino Acid Composition, and Optical Rotation — to assure their purity. Typical specifications include 97-99% purity by HPLC, Amino Acid Analysis ±4% of theory, and Optical Rotation ±5% of literature value.

A Certificate of Analysis is available with each lot to verify the test results. This certificate also assures you that Vega bioactive peptides meet our strict quality control standards.

Vega synthesizes its own peptides using the highest quality reagents. We routinely check purity at frequent intervals during inventory storage. This ensures that product quality is maintained on each lot produced.

To show you how confident we are of our purity, Vega bioactive peptides are guaranteed. If you're not completely satisfied, we'll replace your order or refund your money in full.

As an added benefit, our efficient bulk manufacturing saves you time and money. The peptides you need are available when you need them... at significant savings. Peptides like CRF, GRF, Enkephalins, Substance P Analogs, Bradykinins, Pituitary peptides, Angiotensins, Neurotensins, and many others of current research interest.

Call us toll-free at 1-800-528-4882 and ask for a complete list of our bioactive peptides and biochemicals, all found in the 1983/84 Vega Catalog.

Vega bioactive peptides. They'll get you out of the soup and into consistent research results.

Tomorrow, synthetic DNA will be used as routinely as pipettes are today.

And Biosearch will supply it.

Biosearch is a leader in DNA synthesis, currently supplying synthetic oligonucleotides to molecular biologists who are using them as a routine research tool in such applications as:

- **whole gene synthesis**
- **hybridization probes**
- **selective mutagenesis**
- **linkers and adapters**
- **primers.**

And of course, new applications are appearing every day.

From Our Shelf . . . or Yours!

The question is, will you know where to turn when you need DNA?

To meet our own demand for synthetic DNA, Biosearch *more than a year ago* invented the fully-automatic, chemically-programmable SAM ONE DNA Synthesizer. Today, leading laboratories worldwide are using the SAM ONE to make DNA.

So when the time comes, your choice will be easy: you can order your custom DNA from us . . . or you can make it yourself—automatically.

We'll be ready when you are.

Synthetic chemicals for tomorrow . . . today!

SB9 CENTRIFUGAL FREEZE DRYING

Economical Bench Top Unit

The S.B.9 is a 1 litre capacity Freeze Drier with a built in spin freeze facility. Standard carrier plates accommodate either 116 x 0.5 ml or 24 x 2.5 ml ampoules. A demountable shelf is provided for tray drying and a rubber vacuum value, located on the condenser window, provides for flask or bottle drying. The unit is suitable for general laboratory use or small scale production, and the visible condenser is of particular interest to teaching establishments. A vacuum pump is not provided as standard as many laboratories already have spare pumps available.

Secrecy beyond reason

The Reagan Administration continues to apply widely its demand for secrecy in scientific matters that have any bearing on national security. It is time for more vocal opposition.

CAN only two years have passed since officials of the Reagan Administration were visiting scientific meetings and warning American researchers that academic science was "the soft underbelly" of national security? In 1982, the administration's apparent obsession with the notion that Soviet spies were tricking American scientists into giving away the nation's technological secrets set the government and the universities at loggerheads. In several celebrated cases, the universities (notably and creditably Stanford University in California) refused State Department requests to act as policemen when Soviet and Chinese scholars visited their campuses. To defuse the situation, the National Academy of Sciences published a report, *Scientific Communication and National Security*, which tried to find a reasonable compromise between the legitimate worries of the defence establishment and the traditional commitment of the United States to free and open communication in science. By 1984, technology transfer — at least insofar as it affects the universities — appears to have become the great forgotten issue of US science policy.

A famous victory for the National Academy of Sciences? Hardly. If little is heard about technology transfer, it is not because the Reagan Administration has promptly accepted the recommendations put forward by the academy's report. In a choice irony, the deafening silence from the White House is a product of a decision that the administration's response to the academy's report on scientific communication should itself be kept secret. Dr Frank Press, the academy's president, originally expected an early response from the White House science office. Later, the job was handed from the science office to a senior inter-agency group meeting under the aegis of the National Security Council. Now, the response is believed to be complete but it has been classified as secret.

It would be tempting to believe that there was little cause for concern. After all, most recent cases of government intervention in technology transfer have consisted of efforts to prevent Eastern bloc nations from illegally importing bits of American hardware, such as sophisticated computers. It was always the contention of the universities that technological transfers of that kind — rather than international communication in academic science — were the only really significant examples of hostile countries gaining militarily useful information. The National Academy panel, chaired by Cornell University's former president, Dale Corson, concluded that academic science was a relatively unimportant source of Soviet poaching, and that the dispute between the universities and the administration could be resolved by building tall fences around a very small number of areas of great sensitivity. The universities have been as good as their word; their voluntary agreement to submit papers on cryptography for prepublication screening has, for example, worked remarkably well.

There is however, little reason to suppose that the administration has decided to accept the general philosophy of the Corson report. The available evidence suggests the opposite. Far from agreeing to confine its attention to a small number of highly sensitive technologies, the administration appears to want to extend its control over scientific communication as far as possible. In a little-noticed recent directive, for example, the Department of Defense has begun to insist that all basic and applied contract research it sponsors in universities must be submitted for prepublication screening. Only if the research cannot be placed within a very loose definition of "sensitivity" can it be submitted for publication without pre-screening.

It is too early to say whether this new policy will result in the suppression of articles that could otherwise be published without compromising national security. One hopeful sign is that the Department of Defense has at last set up an internal appeals board to review borderline decisions. But there are also ominous signs that the department's aggressive attitude towards technology transfer is fostering something akin to a siege mentality in which relatively low-ranking officers are opting for secrecy simply because they want to play safe or, in some cases, because they do not understand the complex rules through which the administration's technology transfer policy is being implemented. Recent meetings on materials science, held at the University of Dayton, Ohio, and the University of California, Los Angeles, have been closed to foreign nationals, including scientists from North Atlantic Treaty Organization (NATO) countries. And last month a meeting of the American Ceramics Society in Cocoa Beach, Florida, was split into two halves with one, technically no longer a meeting of the society, being sponsored separately by the Department of Defense and the National Aeronautical and Space Administration and restricted to US citizens.

The prevalence of secrecy in government departments which sponsor scientific research is bad enough. What is worse is the apparent unwillingness of academic scientists to kick up a fuss when unwarranted restrictions are placed on publications and meetings. In 1982, it was the readiness of scientists to insist on the importance of open scientific communication that prompted the National Academy to produce the Corson report. Now that the report appears to have vanished without trace, the need for vigilance is all the greater. □

Time to back Europe

When research ministers meet in Brussels next week, they should back the Commision.

THE French launched the idea of "a European 'space' for science and technology" in their all-but forgotten memorandum to the Athens summit last December. In Toulouse a couple of weeks ago, socialists from the European Parliament backed the same idea. The meeting was unfocused and hence ineffectual, but at least it indicated concern: Europe is certainly not a "space for science", but a polyglot and divided continent where scientific mobility is almost non-existent.

Something must be done! The cry has echoed around the laboratories of Europe for years — but now there is a new determination to find structures that will work, to avoid institutional atrophy and tired bureaucracy. The goal is real, flexible, European collaboration in science and technology.

Even that temple of bureaucracy and powerhouse of paper in Brussels — the European Commission, the executive arm of the European Economic Community (EEC) — is fired with the new zeal. It burns brightest in the person of research and industry commissioner (and vice-president) Etienne Davignon, a Belgian tipped for the presidency next year, and in his director-general for research, Italian biologist Professor Paolo Fasella. With the aid

0028-0836/84/080671-01$01.00

© 1984 Macmillan Journals Ltd

of their enthusiastic staff, they aim to revitalize research in Europe and to prepare the ground for European industries based on the new technologies. That is why, next week, when European research ministers meet in Brussels to discuss Commission proposals, they should have the courage to back them without regard to the suffocating weight of the "budget problem".

The research ministers, who meet for no more than a few hours a year on European issues, must be prepared to delegate some responsibility — and call for European cooperation. The Brussels hierarchy for science has never been in a better state than now to accept the responsibility. Moreover, the Brussels research budget is tiny, less than two per cent of what is spent on research and development by the ten member states, and only a tiny fraction of the total Brussels budget (two-thirds of which goes to support over-productive European agriculture). A little courage to back excellence, in this situation, would go a long way to remind the world — and Europeans — that Europe can be a constructive as well as a destructive union.

Admittedly, Brussels-backed research has had its faults. Even the new $1,000 million information technology research programme, ESPRIT, a key paper on the ministers' table next Tuesday, is not faultless. (It could pay greater attention to training.) The Commission also has a legacy of *ad hoc* research programmes dating from old post-war treaties, and a sometimes burdensome in-house research centre at Ispra near Milan. But almost everything that can humanly be done with this legacy seems to be being done. Last year council approved the "framework programme", which for the first time relates Brussels research support to a list of political priorities, and moves as far as possible towards a conceptual and practical unity for the work. More imaginatively, the Commision launched CODEST, a small group of illustrous technocrats which aims to spend where the money will get greatest leverage: in part, in creating mobility across almost impenetrable European borders and in part on an eight-laboratory collaboration in optoelectronics. All well and good. But when the Commission asked for more cash, the Council of Ministers only managed to approve the principle.

Another item on next week's agenda is biotechnology, where the Commission has proposed a large-scale programme that faces several Community issues (such as feedstock prices). The Commission does not dare hope for approval, but the faintest nod would be encouraging. And the Council should remember a previous far-sighted biotechnology, first put on the table many years ago, which took literally years to approve. The programme, much trimmed, now goes under the title of "biomolecular engineering" and by all accounts is a great success.

What if the ministers fail to provide backing? Suppose they are so frozen in Europe's recrystallizing nationalism that they can offer Messrs Davignon and Fasella — and Europe — no life-line. Is that the end of European scientific collaboration, and so of any hope of a European high-tech reply to Japan and the United States? No, because frustration is bound to spill over into some solution whatever happens to the EEC.

An example is a body called CERFACS, still a dream at present. This proposed "European centre for advanced research and training in computer sciences" is the result of an astronomer's holiday in the Pyrenees, when Dr Jean-Pierre Poyet of the Observatoire du Pic du Midi near Toulouse met a member of the European Movement (out of which the idea for EEC originally emerged). The European Movement in Toulouse, still rather active, was seeking European projects for the region, and Poyet — frustrated by the death of expertise in vectorial computing in Europe (the kind that needs Crays) — invented CERFACS, which would fill the gap. That was a years ago. The idea has been enthusiastically adopted in France, by researchers and industry alike, but if it shows signs of becoming a reality Poyet would like to see it avoid the EEC maelstrom, by becoming a multilateral project. Even the European Parliament appears to agree: it has given money for a feasibility study. The moral: if research ministers refuse to back imagination in Brussels, there is yet hope that it will emerge elsewhere. □

Supercomputermania

Japanese advances should be welcomed by scientists, not treated as national threats.

THE argument of last resort in US science policy debates is inevitably the invocation of the Soviet peril. If that fails, the Japanese peril will do. It is never a very intelligent way to carry on a debate, but in an administration that feels threatened by the Soviets' use of vacuum tubes in their fighter planes and in a country that has been shaken to the core by Japan's ability to build cars that do not fall apart, it hits home. Thus the news that Fujitsu is soon to produce a supercomputer to rival those made in the United States seems to be doing more to excite interest in supercomputing than all past arguments about the urgent need for more supercomputing facilities for US researchers.

This need was detailed most recently by a working group set up by the National Science Board, the governing body of the National Science Foundation (NSF). The working group recommended that NSF commit hundreds of millions of dollars over the next few years to the establishment of academic supercomputer centres to fill the void left by current facilities, which are either in industry (the oil companies, for example, are very interested in numerical modelling of petroleum reservoirs) or the national weapons laboratories (which are very interested, still, in what happens when a thermonuclear bomb goes off). Meanwhile, astrophysicists and chemical engineers, who could benefit from large-scale numerical modelling, have nowhere to go.

The arguments failed to carry the day in this year's budget proposals. NSF is still apparently reluctant to get back into the business of supporting mainframe computer centres, having abandoned that policy years ago in favour of supporting the purchase of laboratory-sized mini- and microcomputers. Most campus-wide computer centres have fallen into disrepute among scientific researchers — whether as a cause or effect of this policy shift it is not clear. Into the breach have fallen the research projects that demand a massive number-crunching capability.

At least NSF director Edward Knapp has been able to announce a modest programme to support the use of existing supercomputers by researchers — but not without invoking the Japanese peril. And there was the start last week of what will surely become a major stir when reports came trickling in from US scientists who had seen prototypes of Fujitsu's new machine, with *The New York Times* printing what is coming to be the standard "Japan outstrips the West" story.

Yet, in reality, the Japanese development is good news for science everywhere. Whether or not the Fujitsu is faster than US machines is not the point. What the Japanese are commendably doing is to develop the software that will make these machines appealing to business as well as scientific users — the Fujitsu will reportedly be compatible with IBM software. Ninety per cent of supercomputer costs are at present spent in developing software peculiar to non-standard machines. If the Japanese can change that, they will sell a good many more supercomputers, which can only bring the price down and allow more scientists access to them. If supercomputers are broght within the reach of more people, more uses will be developed for them. That will be good news to the computer industry everywhere — even to IBM. □

Nature in Tokyo

***Nature* has opened an office in Tokyo. Dr Alun Anderson, for the past few years in charge of the News and Views section of *Nature*, will be in charge of the office for an initial period of one year. By this means, *Nature* hopes more efficiently to cover news of developments in Japan and also to provide tangible help to Japanese scientists wishing to submit research papers or other communications to *Nature*.**

Dr Anderson's address is *Nature*, Macmillan Shuppan KK, Eikow Building, 10-9, Hongo 1-chome, Bunkyo-ku, Tokyo 113 (Telephone (03) 816 3756/7; Telex JATOK J32121 MSKK). □

Illmensee inquiry

Fraud charge unproven, researcher resumes duties

THE commission set up by the University of Geneva to investigate allegations of fraud against a leading embryologist, Professor Karl Illmensee, has concluded that there is no compelling evidence that he fabricated his data. But in a report that is highly critical of Illmensee's experimental records, the six members of the commission are unable to reach agreement on whether "the hypothesis that the protocols were fabricated could be upheld"; some felt it could, others considered "there was no compelling evidence to support or refute the hypothesis". Releasing the full report last week, the university blandly stated that Professor Illmensee is resuming all his duties in the faculty.

The commission had been considering since last August allegations made against Illmensee by three members of his laboratory. The allegations centre on a series of experiments that Illmensee carried out in Geneva between April and August 1982. Growing suspicious of their professor, three members of the laboratory compiled evidence of fraud until, after a talk by Illmensee in January 1983, Dr Kurt Bürki publicly stated that he and his colleagues could not accept the results. An internal investigation of their accusations culminated in what some took to be an admission of fraud by Illmensee (who has since consistently denied it). The rector of the university then publicly announced that the affair would be investigated by a commission which included Dr Anne McLaren of University College London, Professor Pierre Chambon of the University of Strasbourg and professor Richard Gardner of the University of Oxford.

Their report concentrates on three matters — Illmensee's apparent admission of fraud, the numerous errors, discrepancies and corrections discovered in his experimental protocols and errors in a grant application he submitted to the US National Institutes of Health (NIH).

Illmensee's admission amounted to a signed statement that "Protocols of experiments of Dr Karl Illmensee have been manipulated in a way which is contrary to scientific ethics in some period of 1982". It was countersigned by three members of the faculty of sciences of the University of Geneva and dated 17 May 1983. But what exactly did it mean? The faculty members, in a letter that accompanied the statement when it was sent to the dean, said that "Illmensee clearly recognized having falsified ("faked") protocols. . .", a view which they subsequently maintained under questioning by the commission. Professor Illmensee, however, maintained throughout the commission's enquiries and last week that he had admitted only errors in writing up his protocols, not falsification.

Speaking from Geneva, Illmensee said he was so shocked at the accusations made at his meeting with the faculty members that he could not defend himself properly and allowed words to be put in his mouth. Faced with contradictory statements, the commission was finally unable to decide whether Illmensee "did or did not recognize by his signature that experiments were falsified".

It was the day after he signed the admission that Illmensee wrote to NIH withdrawing a sentence, concerned with a particular chimaeric mouse, from his grant application. Faced with contrary evidence, Illmensee acknowledged that the mouse could not be the product of the experiments he had claimed it to be in the application. Subsequently he corrected his "slip" but with a claim that has since become as doubtful as the first. The report concludes: "At the present time, the Commission, as well as Professor Illmensee, do not know which mouse, if any, was the chimaeric male referred to in the NIH grant application." Last week Illmensee disagreed, saying that the words "of two" should replace "if any" since somebody other than himself must have mistakenly mixed up two animals.

As to the accumulation of errors, corrections and discrepancies in his records which, according to the report, "are such as to throw grave doubt on the validity of the conclusions" of the series of experiments, Illmensee admits that his recording system was too prone to error and says that a contributory factor was the stress caused by his impending move to new buildings. He emphasized the report's conclusion that the errors and discrepancies discovered do not bias the results claimed.

Responding to criticism by the commission of his secretive way of working and failure to share techniques with his colleagues, Illmensee said this was exaggerated. He had shared each part of the technique with some colleagues although not every step could be carried out by anyone in his laboratory and certainly not with the level of success he could achieve. The techniques are highly skilled and "it takes Ashkenazy to play Rachmininov properly" said Illmensee.

The report does not reserve its criticism for Illmensee. It is also critical of the university for not making Dr Bürki's written accusations available to Illmensee for several months even though they had been given to other members of the university staff. Moreover, it criticizes those members of the university who felt concerned about the case for not analysing the Bürki report in sufficient detail before drawing their conclusions and not discussing it with Illmensee.

As for Dr Bürki and the two other accusers, the commission acknowledges their sincerity but is mildly critical "of their failure rigorously to assess their evidence" and for their lack of "on-the-spot documentation to support their accusations", because lack of such documentation complicated the commission's task.

Professor Illmensee expressed satisfaction with the way the commission worked (he was allowed to attend all hearings with his lawyer) and with the result. He will now have to reconstruct his laboratory — the accusers and their sympathizers will be leaving — and attempt to repeat the dubious experiments as a collaborative project with full scientific rigour, as suggested by the commission. So far he has no definite plans for that and also has to await the reaction of NIH to his grant application and the Swiss National Fund's decision on a grant that was blocked half way through its 3-year term, pending the outcome of the commission.

Dr Bürki, who did not receive a copy of the report in advance of its publication, said last week that he accepts the report as it is and was glad that the scientific community would be able to read it for themselves. (More than 700 pages of transcripts from the commission's hearings are also open to anyone who wishes to travel to Geneva.) **Peter Newmark**

Orlov appeal

DR Yurii Orlov, the Russian physicist and human rights campaigner, who completed a seven year prison-camp sentence on 10 February (see *Nature* 16 February, p.585), is to serve the second part of his sentence, five years' internal exile, in the Yakut Autonomous Republic, one of the bleakest areas in Siberia.

The decision to send Dr Orlov to Yakutia was taken on 6 February — three days before the death of Mr Andropov. Mr John Macdonald, the London lawyer who has been a noted campaigner for Dr Orlov's release, has therefore made a new appeal to Mr Chernenko "to make a gesture towards the scientific community throughout the world and release Orlov".

To show Dr Orlov that his colleagues abroad have not forgotten him, the members of the "Orlov Committee" at the European Organization for Nuclear Research (CERN) this week applied for a visa for one of their number to visit Orlov in exile, although they realize that the chances of obtaining it are small. More practically, they are organizing their colleagues to send greetings cards and scientific journals to Orlov. The following address should be sufficient: Dr Orlov, Yu. F. Yakutskaya ASSR, Leninskii Raion, Poselok Nurbachan, USSR. Vera Rich

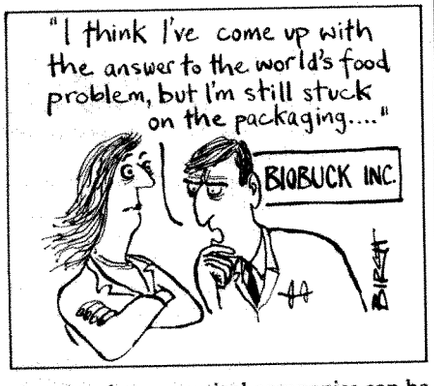
US biotechnology

Information instead of products



Fort Lauderdale, Florida

THE biotechnology industry has been given warning that in the absence of products or revenue it must keep the investment community up to date with as much information as possible on product development, marketing strategies and other internal management and financial plans.

"Uncertainty is the bane of existence for the stock market", said Nelson Schneider of E.F. Hutton at a meeting here sponsored by the Industrial Biotechnology Association to bring together its member companies and representatives of the investment community. Schneider and other stock analysts at the meeting noted that with so many venture capital companies going public, Wall Street finds it difficult enough as it is to evaluate their worth and that conventional methods could easily conclude that many of the biotechnology stocks are in fact worthless.

Robert Johnston of Johnston Associates pointed out that valuations based on such traditional methods as comparisons with other stocks are of little value in biotechnology, where expectations, supply and demand of the stocks and the "greater fool theory" — the belief that a stock is a bargain because someone else is willing to pay more — operate.

Robert Fildes, president of Cetus, retorted that the new biotechnology companies were being asked by the analysts to "take down their trousers", while the pharmaceutical companies' privacy was respected. And he dismissed the analysts' arguments

that the pharmaceutical companies can be rated by their track record and product stream: "What you're saying is that they have a bigger war-chest than we do", he said, "but they'll go under too, eventually, if they don't produce".

Many of the industry's representatives noted that going public is an essential step in raising the funds needed to become a business selling products rather than being merely a research and development firm. Hugh D'Andrade of Schering-Plough said that his company has a sales force of over 5,000. "It's more than brilliant scientists who turn discoveries into products." D'Andrade said that manufacturing expertise, quality control, packaging and management are crucial elements that many of the new biotechnology companies are only beginning to assemble.

The hazards of going public, however, are sufficient to stop some, at least for the time being. Gabriel Schmergel, president of the Genetics Institute, said his company would remain private for the "foreseeable future". He was conscious of the pressures of going public, one of which is the very uncertainty the market feels for the industry. "The long-term nature of our business is not fully appreciated by the public", he said. Fluctuations in the value of stock on the market can be particularly unnerving, he said, both for management and for the staff who own stock.

A number of biotechnology companies, including Genex, Agrigenetics and Genentech, have resorted recently to commercial bank loans to support their operations, which Schneider said may indicate "a useful new movement".

Stephen Budiansky

Nuclear Pakistan

"Islamic bomb" scare resurfaces

THE vexed question of Pakistan's nuclear capability has surfaced again, first in rumours widely reported last month in the Asian press, but since strongly denied, that China had supplied Pakistan with nuclear bombs and second through a published interview with a leading Pakistani nuclear scientist, Dr Abdul Qadeer Khan, director of the Kahuta uranium enrichment plant.

In this interview, which appeared first in the newspaper *Nawa-e Waqt,* and was repeated next day on Lahore radio, Dr Khan said that he felt "cornered" by questions about a possible Pakistani bomb, and did not know whether to answer yes or no. This remark immediately produced a counterblast from Soviet television which alleged that Dr Khan had boasted that it was within Pakistan's capability to create its own bomb. (The Soviet commentator incidentally identified Dr Abdul Qadeer Khan as head of the Pakistani Atomic Energy Commission — a

Harvard's Ptashne patent disappoints

Washington

HARVARD University is embarrassed in its efforts to sell the rights to a fundamental genetic engineering process developed by Professor Mark Ptashne, a Harvard faculty member. After approaching hundreds of companies, Harvard has succeeded in interesting fewer than a half dozen in purchasing a licence to the pair of patents covering Ptashne's invention.

Harvard was trying to duplicate Stanford University's success with the Cohen–Boyer genetic engineering patent, which currently has 68 licensees, each paying a fee of $10,000 a year against future royalty payments of ½ per cent of net sales. The Ptashne patent covers another fundamental step in genetic engineering: the method for attaching a bacterial promoter to a gene of non-bacterial origin, such as that coding for human growth hormone. Harvard, which also wanted $10,000 a year and ½ per cent royalty on sales, apparently misread both the importance of the Ptashne patents and the mood of the industry. Ironically, Genetics Institute, the Boston-based biotechnology company that Ptashne founded and with which he remains closely associated, did not even take out a licence; its president, Gabriel Schmergel, said that Harvard's terms were "onerous" and that "alternative routes to achieve the same end result" of the Ptashne process are available.

Albert Halluin, patent counsel for Cetus Corporation, attributed the poor response to the reluctance biotechnology companies to head down a path of a whole series of basic process patents, each taking a ½ per cent bite out of sales. And he says that the companies have become much more knowledgeable about patents. "After the history of the Cohen–Boyer patent" — the validity of which has come under considerable question since the companies first signed up — "people are saying maybe we should take a hard look at these. Now people have learned that any patent may have flaws if you look hard enough."

Halluin also noted that many companies took licences to the Cohen–Boyer patent at least partly to show that they were "one of the club" of new biotechnology companies. On that basis, and with a cut-price initial licensing offer, Stanford collected more than $3 million from licensees even before the first products were sold. Harvard also announced that stiffer licensing terms would operate after termination of the initial offering — at the end of 1983.

Schmergel cited another reason behind his company's decision: he said Genetics Institute was "upset" by what he termed Harvard's preferential treatment in the granting of exclusive licences on some of its other biotechnology patents to companies founded by the original inventors of the patents — in particular Dr Walter Gilbert of Biogen and Dr Max Essex of Cambridge Biosystems.

Schmergel said Genetics Institute had discussed with Harvard the possibility of obtaining an exclusive licence on the Ptashne patent but had been unable to reach an agreement.

Stephen Budiansky

post actually held by Dr Munir Ahmed Khan, who claims to have little to do with his namesake from Kahuta.)

Dr Abdul Qadeer Khan, in fact, has stressed the entirely peaceful intentions of the Pakistani nuclear programme. He said that unlike India, where the nuclear power programme had been "based from the very beginning on sound foundations" under the patronage of the late Pandit Jawaharlal Nehru, Pakistan had made a relatively late and initially ill-organized start. Moreover, India, at least initially, could get encouragement and help from developed countries, but fear of an "Islamic bomb", which could be disseminated to all Muslim countries, had led the developed countries to impose restrictions on the export to Pakistan of even "the most minor products".

A bomb-making capacity depends, ultimately, on a uranium enrichment facility. On this point Dr Khan did not explicitly commit himself. He claimed only that Pakistan was far in advance of India in uranium enrichment and "not far behind foreign experts" in any field. The Pakistani Government is at present, he said, trying to purchase a 900 MW light-water reactor, and the uranium processing plant at Kahuta was being used to produced the necessary fuel.

Since it would take at least 10 years to obtain, install and operate such a reactor, the Atomic Energy Commission was "positive" that the fuel supply would be ready when needed. Those who thought that the plant was being used for uranium enrichment were deluding themselves, he said. A few minutes later, however, he observed that "as far as the supply of enriched uranium is concerned, we shall supply the Atomic Energy Commission, God willing, with as much as it needs."

Had they come from a politician, Dr Khan's words might well, for reasons of national prestige, be trying to imply a self-sufficiency which has not yet been attained. Dr Khan, however, is a scientist, and moreover, something of a special case. He was sent to study in Europe and them worked at the Almelo uranium enrichment centre in the Netherlands, returning to Pakistan in December 1975. He was subsequently charged, *in absentia,* by the Dutch government with industrial espionage, and he was sentenced, still *in absentia,* to four years imprisonment — a verdict which for prestige reasons, the Pakistan Government is still trying to get reversed.

As Dr Khan admitted in his interview, a special Dutch parliamentary committee appointed to investigate the affair stressed that Pakistan had gained much capability and saved considerable research expenditure on uranium enrichment as a result of his activities — although he maintains that the Dutch judgment was "unjust", "contrary to all the canons of law" and inspired by "anti-Pakistan and anti-Islam" elements.

Vera Rich

Nuclear power

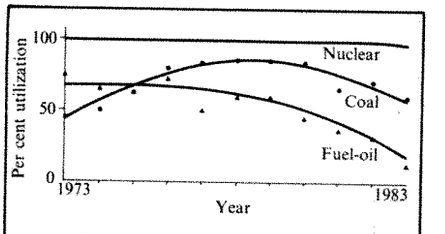
French, plentiful and cheap

THE French national electricity utility EDF is making money at last, despite the enormous cost of the French nuclear power programme, which left EDF with debts of FF 150,000 million (£12,500 million). So claimed EDF director-general M. Jean Guilhamon during a visit to London, in a talk orchestrated by Sir Walter Marshall, chairman of the British Central Electricity Generating Board. Sir Walter, despairing of the future of nuclear power in the United Kingdom, used the opportunity of Guilhamon's visit to sign a fast breeder agreement (*Nature* 9 February, p.495) to ask him to demonstrate that in France, at least, nuclear power works. M. Guilhamon kindly obliged.

The giant EDF debt — in order of magnitude not far from the national debt of Brazil — has been amplified over the past two years by the halving of the value of the French franc against the US dollar — in which currency EDF borrowed much of its capital. But even allowing for making repayments and interest at commercial rates and for depreciation of plant, EDF is now making a profit, says Guilhamon.

France now produces 54 per cent of its electric power by nuclear plant (mostly pressurized water reactors), and with 26 more reactors already under construction or on order, the figure will be 70 per cent by 1990. That is near the practical maximum, given that it is difficult to switch off nuclear power to cope with nightly falls in demand — although EDF is offering customers cheap rates if they will take power nearly continuously.

Opponents of nuclear power have condemned the cost of building the stations, but the tables are now turning, Guilhamon claims. During the construction programme, the government set a low electricity price which made EDF unprofitable, he says. But the price encouraged new electricity consumers: for example, two-thirds of housing starts in France are now all-electric. Now, as more and more nuclear power stations turn on, displacing costly oil- and coal-fired plant, the profits of the programme are beginning to appear.



"In 1976 we were burning 14 million tonnes of oil. In 1984 we will burn less than 2 million tonnes", said Guilhamon. Coal burning has also fallen from 18 million tonnes to 11–12 million tonnes. "So we are now getting a very good return on our investment" at electricity prices at around 30 per cent below those of other countries in Europe.

Guilhamon compared the whole French nuclear power programme, which by 1990 will amount to some 50,000 MW and spare France the purchase of some 50–60 million tonnes of oil, with the scale of British North Sea oil production.

Sir Walter Marshall, meanwhile, openly feared the loss of key British industries to French soil, when in the 1990s French commercial electricity could cost only half the price of British power. Imperial Chemical Industries (Britain's biggest chemicals company) and British Steel might decamp to France, Marshall suggested.

Meanwhile, however, EDF does have a few problems caused by over-capacity and strong political pressure to burn French coal, and so keep the French miners happy. The surplus to traditional French markets will reach 50,000 million kWh in 1990, according to EDF, or around 15 per cent of total production. EDF will seek to place 20,000 million kWh in new markets it hopes to create in industry (for example, electricity to power boilers) and to export the other 30,000 million kWh. Certainly, at present French prices, electricity exports are increasing: 13,000 million kWh last year compared with 4,000 million kWh in 1982.

The pressure from coal, however, may be more difficult to withstand. Last week the government was attempting to arbitrate

Utilization of the average net operating power available from France's power stations. Coal and oil powered plants are used well below their capacity. The 100 per cent figure for nuclear power plants hides the loss in capacity due to structural defects and engineering problems.

between the French mining company Charbonnage de France (CdF) and EDF over a dispute in which CdF insists that EDF must buy fixed amounts of coal, or pay a fixed amount of money to CdF, for the next four years. EDF calculates this would cost it FF 2,500 million (£200 million) a year, essentially to support CdF. EDF does not wish to pay the bill (and since both companies are nationalized, the transfer of funds is somewhat notional); but it may have to.

Robert Walgate

● Meanwhile, accountants commissioned in 1982 by the then British energy secretary, Mr Nigel Lawson, to look into CEGB's pricing policy have argued forcefully that British electricity was not only over-priced (Sir Walter Marshall would agree with that — the government has set the price too high, he says) but ineptly priced (a comment less palatable at CEGB). The complex calculations by which the CEGB set its rate to bulk industrial customers are not based on sound economics, the accountants say. A proper pricing formula would result in cuts of 5–10 per cent followed by a few years' freeze. □

West German universities

Minister responds to Knopp

LAST week, West German Minister of Education, Dr Dorothee Wilms, announced her intention to recast the federal university law in line with the recent Knopp report (*see nature* 26 January, p.305). The existing law, the 1976 *Hochschulrahmengesetz* which was designed to provide a unifying framework within which the *Länder* could develop their own legislation, was brought in by a social democratic (SDP) government. Now in opposition, SDP finds the commission asked the wrong questions and came up with the wrong answers. "Partly useless, partly unnecessary, and partly reactionary", commented Eckart Kuhlwein, SDP spokesman.

On the other hand, the West German Rectors' Conference (WDRK), representing the heads of universities, agrees with the report that modest change is needed to create more flexibility within which the *Länder* can act, especially in the areas of personnel, career grades and financing from sources outside the universities.

Controversy still centres on the power of the professors — of feudal proportions before the 1976 law. The report suggests strengthening faculty representation and ensuring professorial majorities in decision-making processes. Both the government and WDRK favour this change. The vice-president of the Free University of Berlin, however, has pointed out that this is tantamount to a return to hierarchy and less equality, towards scientific freedom away from communal control in the coordination of teaching and research. He points out that the universities could not have met the challenge of increasing student numbers without the middle grades of academic staff, which the report suggests should in future assume a still lower position relative to the professors.

A recent conference at the Berlin Aspen Institute pinpointed the failure of West Germany's universities to produce the quantity and quality of trained people the country needs. Large numbers of students, straitened finances, long periods of study, and centralized administrations have created a system in which it is often impossible for the gifted student to distinguish himself. Employment bottlenecks on the academic ladder make it difficult to maintain the pool of academic talent. One highly controversial remedy was presented by the Free Democratic leader and Foreign Secretary Hans-Dietrich Genscher, who restated his party's support for private universities and institutes. A positive comment on the private university at Wittne/Herdecke suggests that the Christian Democratic administration warms to this idea. Others point out that private can mean second-rate.

Policy formation for West German higher education is inscrutable to the point of opacity, emerging from a fog of relationships between the *Länder* and federal institutions and a series of quasi-official advisory bodies, including WDRK, the Wissenschaftsrat, the Conference of Ministers of Culture and the Federal-Land Commission for Educational Planning. These bodies are criticized for being outside parliamentary control, for their obscure nomination procedures, for overworking senior personnel, for consensus policies, and for a general lack of democratic legitimacy and openness.

This system will produce the new *Hochschulrahmengesestz*, which must also be seen as one facet of the administration's overall drive for industrial growth based on science and technology. **Sarah Tooze**

China

Storm over beancurds

AN attempt by the director of a Chinese research institute to add "technological pilferage" to the list of ideological shortcomings against which there is a current drive in the country has backfired. As a result, Ge Fengheng, director of the Liaoning Provincial Commercial Science Research Institute, has found himself the object of a campaign against "local monarchs in science" that may be widely applied.

The incident, known as the "beancurd storm", began last October when an engineer from the Liaoning Institute, Wu Wentao, read to a meeting on food additives a report about a new variety of "liquid beancurd" he had developed. This evoked widespread interest, since beancurd, a staple protein source, is in short supply in many places in China, and the new product could do much to fill the gap. A special meeting of the institute's academic council was accordingly convened, at which director Ge congratulated Wu and immediately accused him of "pilferage". According to Ge, Wu had presented his work without asking the institute or reporting to it afterwards, worked on a project not assigned by the institute, included foreign data in his report, and placed special emphasis on his use of additives to distinguish between his beancurd and other types already in production.

The Liaoning Commercial Department ordered an investigation, and on 7 December reported that the production of such beancurd was unnecessary. By this time the distinguished journal *Shipin Gexue* (Food Science) had published Wu's preliminary research report. This apparently brought the matter to the attention of the party newspaper, the *People's Daily*, which discovered that during the past few years, Ge had repeatedly criticized the work of the institute's researchers as "pilferage", forbidding them to discuss the line their research should take, and used his position and power to penalize those who showed signs of opposing him. As a result, *People's Daily* concluded, there had been "serious losses" to the prestige of the party and to the "party's cause of scientific research".

The "beancurd storm", says *People's Daily*, has implications far beyond Liaoning, raising the issue of the personal qualities needed in the head of a research institute. Beijing radio went even further: "local monarchs" like Ge would not have been able to function were there not also "mistakes and a bureaucratic style of work" in the bodies responsible for administering the country's science. **Vera Rich**

Italy's biotechnology

FAST action

Milan

ALTHOUGH basic biotechnological research is good in Italy, the same cannot be said of its application in industry. Thus concludes a report on Italian biotechnology published by the Federation of Scientific and Technical Associations (FAST), which calls for the establishment of a study committee to decide on some priority applications.

That call was endorsed by Luigi Granelli, Minister of Research, in welcoming the report. At last, he said, Italy has an exhaustive survey of the state of the art of biotechnology in the 150 Italian institutes where relevant research is carried out. The FAST report, added Granelli, is a realistic guide to combining public and industrial efforts in biotechnology, particularly at a time when Trieste is likely to be chosen as one of the two sites of the United Nations Industrial Development Organization's International Centre for Genetic Engineering and Biotechnology (see *Nature* 16 February, p.583).

The report was edited by Professor Gabriele Milanesi of the Biochemical Genetics Institute in Pavia. The message of the survey is that basic research in biology in Italy compares well with other European countries, thanks to recent university law and to the projects supported by the Consiglio Nazionale delle Richerche, Italy's principal research council, in continuance of the policy implemented since the 1950s by the late Professor Adriano Buzzati-Traverso. By contrast, industrial applications are poor despite the involvement of three public companies (Farmitalia-Carlo Erba of the Montedison group, Assoreni and Sclavo of the Eni group) and five private companies (Sorin Biomedica of the Fiat group, Lepetit, Recordati, Soreno Institute and Societa Produzione Antibiotici) and despite the fact that industry cooperates with public centres by investing in basic research. **Paola De Paoli**

Satellite launchers

Ariane backers confident

Evry, France

IN France, where they build Ariane, Europe's answer to the US space shuttle, one newspaper last week reckoned the score in own goals to be: Shuttle 3, Ariane 2. That is, the shuttle has lost one more communications satellite than Ariane, although it has regained one too. Certainly this leaves the space insurance business equally nervous of both systems.

But at Evry, south of Paris, from where the French space agency CNES and the commercial launcher company Arianespace run the Ariane programme, there is an increasing sense that Ariane may prove to be a winner in the billion-dollar market for communications satellites.

Without any sense of crowing over shuttle problems — for Ariane has had its own, and may yet have more — it is pointed out at Evry that launch from the shuttle into geostationary orbit is more complicated and more expensive than launch by Ariane. A communications customer on the shuttle must also buy a substantial rocket — the "perigee motor" — to lift the satellite from the low shuttle orbit to the elliptical geostationary transfer orbit (GTO), which reaches up to the parking height of geostationary satellites. It is these motors that failed in the recent shuttle flight. Ariane reaches GTO in one shot, using liquid fuel stages which are theoretically more accurate and reliable.

However, even if there is some delay in the shuttle's geostationary launch programme, Arianespace is not in a position to gain any immediate benefit. Its order book is almost full for two years, with room (perhaps) for only one more "good" customer in 1985.

The limiting factor is the Ariane production line, which can turn out no more than six launchers a year. From 1985, the launch site at Hourou, French Guiana, will be able to cope with 12 launches a year. So Arianespace, which is desperately undercapitalized (it could be bankrupted by a single launch failure), is seeking new capital in Europe to construct a second production line.

In the long run, however, much depends on the Ariane development programme. So far, Ariane launches have used only the first version of Ariane. A week ago, the last tests were completed on the second and third versions (Ariane-2 and Ariane-3, identical except that the latter has two extra strap-on solid boosters in the first stage). The first new version launched will be an Ariane-3, due to take the European Space Agency's ECS-1 and the French Telecom 1-A aloft this July. To maintain confidence in Ariane, of course, the new rocket should not suffer the teething troubles of Ariane-1 — which suffered high frequency vibrations in the first stage (causing failure of the second launch test) and then lubrication failure in the upper stage cryogenic fuel pump (that knocked out the fifth). According to the man in the hot seat, the *Chef de Projet* for Ariane-3 (and a future Ariane-4), André Van Gaver, the problems that hit Ariane-1 are now solved — or as solved as anything can be in the space business.

After Ariane-3 will come Ariane-4, the first parts of the first flight model of which are to be completed this year. Ariane-4, to fly in March 1986, is designed around the next generation of communications satellites led by Intelsat VI: 4,200 kg and approaching 4 metres in diameter, comparable with the shuttle bay's 4.5 metres. The future of Arianespace depends on the company's success in gaining contracts for the Intelsat VI series, but knowing this, Intelsat can afford to wait. Around half the Intelsat business would be ample to give Arianespace a living, says Van Gaver.

The United States "made a mistake" in dropping conventional launchers in order to push business towards the shuttle, Van Gaver believes. Now the United States is trying to commercialize the old launchers (Thor-Delta and Atlas) "but we have yet to see any contracts".

Ariane's other competitor is probably Japan — Van Gaver does not see the Soviet Union or China entering the Western telecommunications market. Japan's space programme is at present uncompetitive, but the Japanese space agency is developing a large cryogenic engine (such as Europe would only see on Ariane-5, now at the planning stage). "We must watch Japan carefully" Van Gaver says.

Robert Walgate

● Intelsat, the international communications satellite organization, has finally decided to go back to an old design for Intelsat V F8, due for launch on Ariane on 5 March. Problems with the L-band maritime communications system (see *Nature* 2 February, p.401) had pushed the launch back two months. Inmarsat, the organization which uses the L-band system, has complained that Intelsat V F7 is unworkable and has refused to accept it. Unable to solve the problem on F8, Intelsat has gone back to the F6 design, which still has problems but not so bad as those of F7. F9, which was to have been launched by Ariane this summer, has now been put back to 1985. □

US space station

Manufacturing plans launched

Washington

WITH a masterly sense of timing, the National Aeronautics and Space Administration (NASA) has announced that a major company, the Minnesota-based 3M Corporation, is planning to embark on a new programme of space research with the aim of eventually producing commercial products in orbit. The corporation's decision comes fast on the heels of President Reagan's announcement that the United States will build a manned space station within a decade, and is being portrayed by NASA as vindication of its claims that a space station could become the nucleus of a sizeable space-based manufacturing industry.

At a formal ceremony announcing 3M's plans, NASA administrator James Beggs did his utmost to link the company's decision with the President's approval of the space station. 3M, he pointed out, was the first non-aerospace corporation to sign a memorandum of understanding with NASA since the space station was approved. He said the deal would hasten the day when US industries were as comfortable with factories in space as they were with those on Earth.

NASA's enthusiasm is understandable. To persuade Congress to fall in with its plans for a space station, the agency must show that private industry (and foreign governments) are prepared to pick up a share of the tab. Propaganda value apart, the agreement with 3M looks decidedly one-sided. In return for expressing an interest in space, 3M scientists will receive free access to NASA laboratories where materials processing research is under way. 3M also gets two free flights on the shuttle, the first as early as August.

3M's research programme will focus on processing organic materials in the low-gravity, high-vacuum environment available in space. Its vice president for technology services, Dr R. M. Adams, said the company's first experiment on board the shuttle would look at the growth of organic crystals and the development of thin films with novel physical and chemical properties.

Directed by both President Reagan and Congress to encourage commercial investment in space, NASA faces an uphill struggle in extending commercialization beyond its one great success story — the satellite communications industry which does more than $2000 million of business a year. The most visible commercial interest in space-based manufacturing has come from Johnson & Johnson and McDonnell Douglas, which are developing a prototype instrument for the large-scale production of drugs by electrophoresis in space.

To garner more investment, NASA plans to offer an expensive array of incentives including free or subsidized flights on the shuttle and access to NASA expertise. That could queer NASA's pitch with academic scientists, many of whom have been grumbling for years about the length of the waiting list for space on the shuttle.

High-energy physics

Future accelerator plan

Chicago, Illinois

AN enormously powerful colliding particle accelerator, the Superconducting Super Collider (SSC or the "desertron"), may still be only a gleam in the eye of US physicists but last week a workshop on the options for the proposed machine brought its construction a little nearer. SSC, at 20 TeV per beam, would be 20 times more powerful than even the Fermilab collider, which is still under construction.

The workshop, held at the University of Chicago and co-sponsored by Argonne National Laboratory, brought together about a hundred high-energy experimenters and theorists to sharpen the arguments on the relative merits of proton–proton colliders and antiproton-proton colliders. Either could still be the basis of SSC, which was recommended last year by the US high-energy physics community as the next big step in US accelerators.

Antiproton–proton colliders — such as the one at the European Organization for Nuclear Research (CERN) at Geneva and that being built at Fermilab — can circulate both types of particles within the same beam pipe and thus need only one ring of magnets. At 90 km in circumference, a one-ring SSC could cost considerably less than a two-ring proton–proton machine. However, antiprotons cannot be produced as copiously as protons. Antiproton colliders thus have lower luminosities and produce fewer particle interactions.

But the disadvantages of an antiproton collider may not be so great as had been thought. For example, the antiproton source group, headed by James Simpson of Argonne and Thomas Collins of Fermilab, concluded that antiproton sources can be built that would provide luminosities greater than 10^{32} per cm^2 per second. This approaches the 10^{33} that has generally been assumed possible in a proton–proton machine and necessary for much of the expected physics. In addition, most of the groups reported that luminosities much above 10^{32} would usually be unnecessary.

A proton collider can always be made more luminous than an antiproton machine, Collins told his audience. "But let's not choose a machine based on capabilities that we don't really need." However, the groups studying tests of electroweak interactions and potential new particles and interactions decided they could sometimes use all the luminosity they could get. Others, according to Robert Cahn of the Lawrence Berkeley Laboratory, really would like both types of collisions. But when the next major workshop on SSC takes place in June at a three-week meeting in Snowmass, Colorado, the participants will have two strong candidate accelerators to consider. **Larry Arbeiter**

UK pollution control

Commitment urged

THE Royal Commission on Environmental Pollution, in its 10th report, published this week, urges the British Government to "play a more positive role" in promoting environmental issues in the European Community. In a survey of its 14 years of offering advice on matters of pollution, the commission concludes that British commitment to international action "has not always been as strong as it might be". And on the vexed question of acid precipitation, concern over which is currently spurring several EEC draft directives on air pollution, the commission says that the Central Electricity Generating Board (CEGB) should within the next five years introduce pilot plants to investigate the various options for reducing emissions of sulphur dioxide from its power stations.

The EEC draft directives on air pollution controls, which are being pushed hard by West Germany, are currently the subject of an inquiry by a House of Lords Select Committee. This week the committee will hear a CEGB claim that one of the major proposed directives (on large combustion plants) misquotes figures from a cost-benefit analysis of sulphur emission reductions. The Confederation of British Industry and the Chemical Industries Association will join CEGB in condemning the draft directive as "excessive" and "very damaging". It calls for, among other things, a 60 per cent reduction in total national emissions of sulphur dioxide and fixed emission limits for sulphur dioxide from large plant. A separate draft directive on air quality limits for nitrogen oxides is also attacked for being too stringent.

The Royal Commission on Environmental Pollution has very widely drawn terms of reference and has never been afraid to use them. The commission, whose present chairman is Professor Sir Richard Southwood, Linacre Professor of Zoology at the University of Oxford, delivers a well-aimed swipe at Whitehall officials who have allowed ministers "unfettered discretion" over timetables to frustrate the wishes of Parliament. Implementation of the 1974 Control of Pollution Act has been piecemeal and incomplete, according to the commission, and "reflects little credit on successive administrations". Such action as has been taken is ascribed to pressure from the EEC. The lack so far of any government response to several of the commission's earlier reports is described as disappointing.

Official secrecy over pollution control has long been a controversial issue in Britain, and the latest report from the commission reaffirms its position firmly on the side of the "right to know" camp. No less than ten detailed recommendations urge greater public access to information compiled by pollution enforcement authorities. The commission says that " a guiding principle for all legislative and environmental controls . . . should be a presumption in favour of unrestricted access" with provision for secrecy only in exceptional cases. Observing that secrecy fuels fear, the commission draws attention to public anxiety over nuclear power and calls for greater public representation on bodies concerned with managing nuclear waste.

Recognizing that there is a growing awareness of the urgency of international pollution problems, the Royal Commission advocates more forward planning of measures designed to avoid pollution before it becomes a problem. Thus it recommends government support for research into new potential pollutants from high-technology electronic and biotechnology processes, as well as more "traditional" pollutants in air and water. The government should also study how pollution control equipment is subsidized in other countries with a view to introducing subsidies in Britain. The commission says the politician faced with decisions on pollution control "cannot wait for rigorous proof": prudent abatement practices must be instituted when perceived risk of damage justifies the cost of alleviation. It therefore proposes that decision makers should be guided by principles of the best practicable environmental option and the best practicable environmental timetable. The commission ends by lamenting the decreasing emphasis on environmental protection in Britain and the concomitant decrease in resources. **Tim Beardsley**

Acid rain

Canada must act alone

Washington

THE Canadian Government, exasperated by the Reagan Administration's decision to do no more than continue research on the acid rain problem, is considering substantial unilateral curbs on its sulphur dioxide emissions.

In 1982, Canada unilaterally decided to institute a 25 per cent reduction by 1990 in sulphur emissions. It has since been hoping to negotiate further cut-backs as part of an overall agreement with the United States in which both parties would work to reduce transboundary sulphur pollution. Although sulphur emissions from both countries cross into the other, Canada suffers most from transboundary pollution.

The Reagan Administration has consistently refused to order reductions in US sulphur emissions, arguing that scientific uncertainties must first be resolved. That position was reiterated most recently by science adviser George Keyworth in his briefing on Reagan's 1985 budget proposals, which include funds for more research on acid rain, but no regulatory action. The administration, in maintaining this position, has ignored the recommendations of both the National Academy of Sciences and a panel of scientific experts assembled by the White House Office of Science and Technology Policy. The White House group last summer found that although scientific uncertainties do exist, new regulatory action is justifiable because of the possibility of "irreversible damage" to the environment by acid deposition.

Canada's current programme involves reducing sulphur emissions 25 per cent below the levels already required to meet ambient air quality standards instituted in the mid-1970s. Canada's ambient standards are at least as strict as US standards and, like them, are designed to protect human health from acute effects of sulphur dioxide rather than to control acid rain.

Bruce Jutzi of the Canadian Embassy in Washington says that while Canada had not yet decided to institute new curbs, such action is under serious consideration. "Now that it's apparent there's nothing for the foreseeable future to be done together, that puts the onus back on the Canadian Government", he said. Jutzi said that ultimately Canada expects to have to reduce its sulphur emissions by 50 per cent from the ambient standards as its contribution to solving the transboundary pollution problem. "I'd personally be a bit surprised to see us go all the way to that limit without any movement from the United States", he said.

Canada's main source of sulphur emissions is smelters; in the United States it is coal-fired power stations.

Stephen Budiansky

Conservation

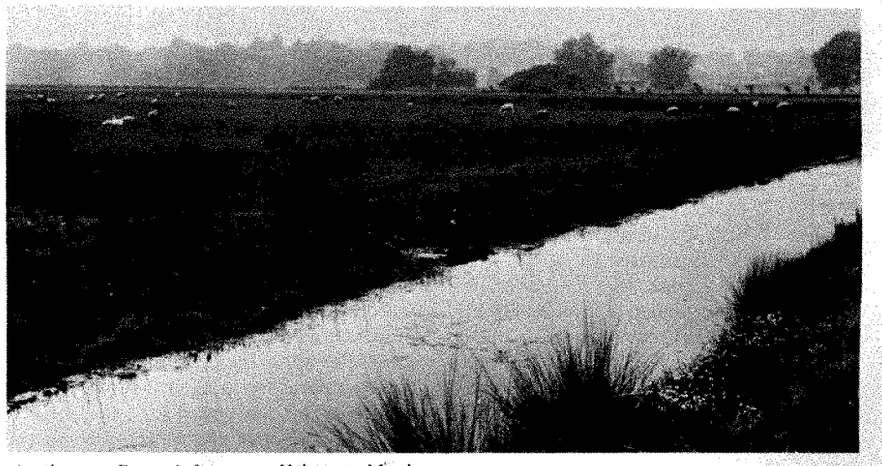
Farm policy hits Broads

CONSERVATIONISTS in Britain are anxiously awaiting the outcome of a local dispute that is seen as a major test of the 1981 Wildlife and Countryside Act. The question is who should pay the compensation that the act offers to landowners who agree not to turn valuable habitats into farmland. The growing incentives to produce more farmland were stressed last week at a meeting called to discuss the ecological crisis facing the locality.

The dispute concerns Halvergate Marshes, close to Great Yarmouth in eastern England, and has arisen because the Broads Authority, set up in 1978 to safeguard the whole of the Norfolk Broads of which Halvergate is a part, claims that it cannot afford the level of compensation involved. Two thousand acres of grazing marsh have been turned over to arable farming in the past 3 years and according to one estimate another five thousand acres could be ploughed within the next 5 years, unless compensatory payments of up to £200 per acre per year are found.

The problem of much of broadland is that it is very expensive to protect, having a high amenity value to tourists (whose boats are eroding the river banks) and to farmers (who drain and turn to the plough the prized grazing marshes in order to take advantage of the generous guaranteed prices laid down in Brussels). And so the area tends to throw into sharp relief conflicts of interest, and tests to the limit the legislation designed to resolve them.

The essence of the Wildlife and Countryside Act is that designated authorities wishing to protect a site from some planned action must, if persuasion is ineffective, be prepared to pay the owner for loss of projected profits. For arable farming these can be high, and the Broads Authority says it cannot afford to pay for these "management agreements". Half of the authority's income comes from the local councils of the region, while the other half is from central funds through the Countryside Commission. The authority, which comprises local authority representatives, has refused to continue making payments on these terms.



In areas designated as National Parks (which the Broads are not), 75 per cent of local compensation agreements are met from Government. But the Countryside Commission, itself the government's adviser, has argued strongly that 90 per cent reimbursement would be more appropriate for the Broads Authority. Representatives of the authority are soon to meet Mr William Waldegrave, Under-Secretary of State in the Department of the Environment, to thrash out a solution.

The powers of the Broads Authority have recently been the subject of a searching review by the Countryside Commission, which next month will formally recommend to government that it should be given special statutory powers to coordinate a rescue plan for the area.

The main problems facing broadland are that raised nitrate and phosphate levels cause algal blooms which shade out bottom-living plants. Consequently, banks erode more quickly, much wildlife disappears and sedimentation rates increase. Some ecologists fear that the expansion of arable farming may have wider consequences in the region.

Last week, two learned societies spent a day discussing the ecological crisis facing the Broads and heard speakers express concern that the European Community's Common Agricultural Policy and grants from the Ministry of Agriculture, Fisheries and Food will encourage the loss of much of the remaining grazing marsh in the area. At the end of the day, representatives of the British Ecological Society and the Linnean Society of London were told by their chairman that while it would be "entirely inappropriate" for them to pass a resolution expressing concern on the issue, it would be in order for a report on recent research "showing the scientific consensus" to be prepared and despatched to relevant government officials.

McNamara's plan

SIR — We suggest a strategy for global disarmament of nuclear weapons: that all land-based missiles carrying nuclear warheads be destroyed. We refer to a statement by Robert S. McNamara in *Newsweek* of 5 December 1983 and repeated at the meeting of the Bellerive Group in Geneva last December that nuclear weapons have no military use whatsoever other than to deter one's opponent from their use. With the words of Professor Robert Neild, Cambridge, at that same meeting: "we could draw back the nuclear weapons to where they belong, deep in the oceans, where they could serve the sole purpose of deterring nuclear attack or threat". We note that there seems to be general agreement that a limited nuclear exchange cannot be confined, but will lead to a general exchange of strategic weapons. If so, land-based missiles do not add to deterrence over and above what submarine-based missiles can achieve.

The nuclear arms deployed on land thus only reduce the security of the nations possessing them. The risk of nuclear war triggered by accident or misinterpretation (such as a computer error or an astrophysical phenomenon such as the 1908 Tunguska event misinterpreted as a nuclear attack) is greatly increased by the mere presence of stationary nuclear weapons on the continents which, being vulnerable, call for a fast response. Submarine-based nuclear missiles cannot be easily found or destroyed by enemy forces and thus do not invite overreaction in response to or in anticipation of a presumed first strike.

The specific disarmament measure we suggest can be undertaken unilaterally without any loss of security. Any nuclear power implementing this strategy will gain a colossal political victory.

Improper psychiatry

SIR — I was interested to read (*Nature* **304**, 293; 1983) that ". . .remaining members (of the World Psychiatric Association) should put their houses in order. . .". You meant, I suppose, that neither unconditional nor automatic legitimacy should be granted to WPA when, as now, the bad boys are out. I cannot but agree with such a view. However, in the same article, you use the term "mental illness" when referring to several types of anomalous human behaviour. The nature and/or the very existence of such "illness" remains a matter of debate, as you make clear, so I find it misleading when such "illness" is referred to later in the article. This shows how hard it is to avoid the use of an ambiguous term, even in a scientific journal.

This confusion could lead the reader to believe that scientifically unequivocal correlations have been found between truly existent mental illnesses (of a total physical origin), social danger (as an effect of such an illness) and treatments (scientifically based). Of course, if such correlations exist, they are far from being unequivocal and, beside mental "illness", social danger seems to be of a very doubtful consistency too. Even more doubtful is the therapeutic value of treatments based on physical modifications of the human brain (electroconvulsive therapy, lobotomy, heavy drugs) which, it is claimed, work simply as repressive tools. This is as close to torture as to therapy.

Put simply, the problem of ill use of psychiatry is psychiatry itself. The alleged use of psychiatry in repressing political dissent — an extreme degeneration of an already strongly criticized activity — provides an opportunity for pushing WPA and the United Nations to face their responsibilities. As for the Soviet Union's resignation from WPA, it should not be welcomed unconditionally, as it can be justified as a way of maintaining social prestige, credibility and income for the remaining members of WPA. Moreover, unpleasant though it is, we must face the possibility that such a resignation can be represented as a protest or a Soviet psychiatrist's refusal to play the role of scapegoat.

Finally, can we be sure that the type of abuse of physichiatry as documented by various international human rights organizations happens only in the Soviet Union? Should we draw the sad conclusion that what in the Soviet Union is done for political reasons is done elsewhere for ill conscience and/or for material benefit?

Frost tolerance

SIR — Current ideas on the protection of plants from frost by alteration of the characteristics of the bacteria normally resident on the leaves raises an environmental question because of the differences between resistant and non-resistant plants, and the role of supercooling in each of these when they are exposed to frost.

The cultivated potato, some beans and the dahlia are examples of non-resistant plants which are damaged by ice forming within their tissues but not by sub-zero temperatures if no ice forms. This is possible if the water they contain supercools as the temperature passes below freezing point. In the great outdoors, the surfaces of leaves are normally quite dirty with all manner of material, some of which may be expected to be of the sort which encourages water to freeze when the temperature falls below zero. The connections between events on the surface of leaves and the freezing of water within are unclear, but it is certainly true that the freezing of dew on the surface can lead quickly to ice formation within. It has been shown that some bacteria normally resident on leaves are able to encourage ice formation by virtue of some property of their coat. Genetic engineering has succeeded, it is claimed, in creating forms of these bacteria which lack the ability to trigger ice formation in water below its freezing point. It is also being suggested that if the natural population of bacteria on leaf surfaces of frost-susceptible crops could be replaced by these altered forms, then the plants would be less likely to freeze during frosts and so avoid damage.

Some cases of frost resistance by avoidance, apparently involving a thick water repellent cuticle, are known in natural vegetation. However, the majority of frost-resistant plants are quite different, they are tolerant of freezing dew and the formation of ice within the leaves and stems. Although like non-resistant plants their cells are killed if ice forms inside them, there are mechanisms which ensure that ice forms only between the cells and in less important tissues; the cells become desiccated due to water loss to the intercellular spaces, but few freeze. These mechanisms take time to work, and it is essential that in these plants the process of ice formation begins as soon as possible after the temperature falls below zero. Frost-tolerant vegetation is usually inoculated by freezing dew which sets off internal ice formation, and if this triggering fails, as it does when there is no dew because the air is too dry, then the subsequent "black" frost is more than usually damaging. The reason is that the plants have supercooled to a temperature well below zero, and when ice formation eventually begins it is a very rapid process. This is damaging because the movement of water out of the cells to the growing ice crystals cannot keep up with the rate of ice formation, and the ice grows into the cells and kills them.

Because of the different role of supercooling in the survival of these two main categories of plants, the expected results of any treatment which encourages supercooling will be different too. The question is, what may happen if such a treatment, carried out on a crop, also affects the surrounding natural vegetation? If the treatment works at all, the crop may be less damaged but the natural vegetation may be more damaged than would have been expected from the severity of that particular frost, unless the frost were so slight that both types of plant survive by supercooling.

Polygraphic interrogation

David T. Lykken*

The polygraph ("lie detector") test is wrong one-third of the time overall, biased against innocent and conscientious persons, and can be "beaten" by sophisticated liars. Increasing use of this technique, in the United States and soon in Britain, is a cause for alarm.

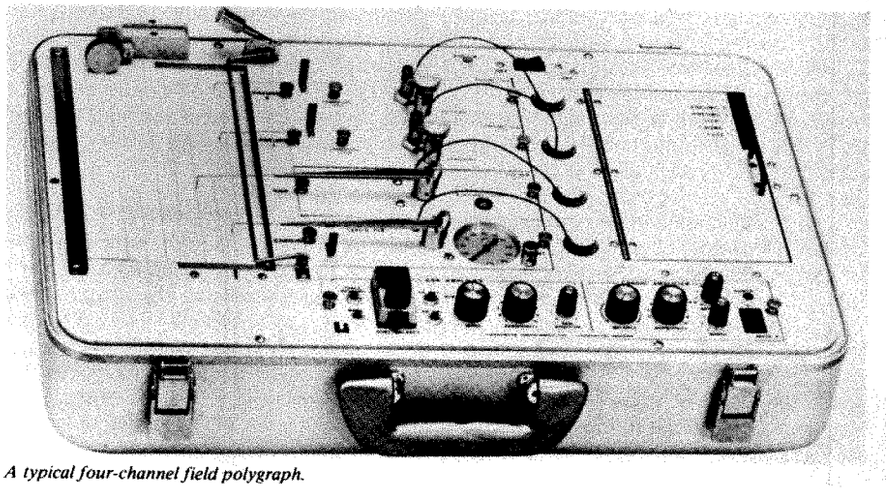
THE origins of lie detection are lost in the mists of prehistory. When *Homo sapiens* developed language, one suspects that he soon began to use that language to mislead and deceive, mendacity following hard upon capacity. This in turn required all of us to become human lie detectors.

Although most of us can probably detect lying with better than chance success using just our eyes and ears and commonsense, some are less skilful than others. It is interesting that English, at least, is replete with terms descriptive of the low end of this dimension of talent ("gullible", "credulous", "sucker" and so on) yet apparently empty of descriptors for the skilled end ("suspicious" is biased, "perceptive" is too broad). The ancients developed rituals and ordeals for identifying liars, some of which, like modern lie detectors, relied on the autonomic arousal that accompanies fear. One often-cited trial required suspects to chew a mouthful of rice and then attempt to spit out a moist bolus. When the rice grains clung to the dry mucosa or dribbled individually from the parched and trembling lips, the priests believed that they had found their culprit[1].

In London in 1730, Daniel Defoe published a tract entitled *An Effectual Scheme for the Immediate Prevention of Street Robberies and Suppressing All Other Disorders of the Night.* Defoe argued that "there is a Tremor in the Blood of a Thief, that, if attended to, will effectually discover him". "Some are so hardened in Crime", he continued, "that they will . . . outface even a Pursuer; but take hold of his Wrist and feel his Pulse; there you will find his Guilt."

The first modern to take up Defoe's idea was also a writer of popular fiction, the inventor of the comic-strip character *Wonder Woman*. William Moulton Marston, a Harvard-educated psychologist and lawyer, realized, however, that fear symptoms alone are ambiguous for there may be a tremor in the blood of an innocent accused as well. Marston, who either coined the term "lie detector" or took up the phrase from one of the journalists whom he cultivated, believed that there is an involuntary physiological response, like the elongation of Pinocchio's nose, that we show when, and only when, we lie. This specific lie response, Marston claimed, is a transitory elevation in systolic blood pressure brought about by the interaction of fear of detection and the attempt to maintain outward composure[2].

The polygraph



A Californian police officer, John Larson, soon developed the first recording polygraph which made continuous tracings of breathing movements and "average" blood pressure. On a moving paper chart, the "cardio" pen, connected pneumatically to a standard blood pressure cuff on the subject's arm, deflects briefly with each heart beat and the entire "cardio" tracing moves up or down with transitory changes in blood pressure. While it soon became obvious to Larson that Marston was mistaken, that innocent persons too may show blood pressure responses to accusatory questions, he nonetheless found his polygraphic lie detector to be a useful investigative tool. When questioning a series of possible suspects in some crime, it often happened that one of them would display a really strong reaction to the relevant or accusatory question and, moreover, when confronted with this evidence of internal disquiet, such suspects would frequently confess.

Like the rest of us, police have always looked for blushing, trembling, averted eyes and other signs of guilty nervousness when questioning someone whose testimony is in doubt. Here was a scientific instrument that could record internal blushes and other "tremors in the blood" and which seemed to be effective. The standard modern polygraph is not much different from Larson's. Two pens are driven by pneumatic tubes placed about the subject's chest and stomach, recording thoracic and abdominal breathing movements. The "cardio" pen is still attached to a blood pressure cuff which, during the test, is inflated midway between systolic and diastolic pressure, partially occluding blood flow to the arm. The fourth pen is connected electrically to a pair of metal electrodes on the subject's fingers: it records changes in the electrical resistance of the skin, electrodermal responses which reflect sweating of the palms.

A single polygraph chart is a continuous record of these variables over the 4 or 5 minutes required to ask a series of about 10 questions; at the end of each chart it is necessary to release the cuff pressure for a time to restore circulation in the arm. Most polygraph tests involve three charts, three repetitions of the same list of questions.

The relevant/irrelevant test

Leonarde Keeler, Larson's assistant, developed a portable polygraph instrument and, in 1930, moved to Chicago where he established the Keeler Polygraph Institute, the first school devoted to the training of polygraph examiners. There are now dozens of such schools in the United States,

A typical four-channel field polygraph.

*Department of Psychiatry, University of Minnesota, Minneapolis, Minnesota 55455, USA.

0028-0836/84/080681-04$01.00

© 1984 Macmillan Journals Ltd

more than 20 in Florida alone, most of which offer a curriculum lasting from six to eight weeks or about one-sixth of the study time required by the average barber college.

The standard Keeler polygraph test involved a series of relevant or "Did you do it?" questions ("On 15 May, did you take the $1,000 from the safe?") intermixed with a number of innocuous irrelevant questions ("Is today Tuesday?"). Since the relevant questions can span a lot of territory ("Did you tell the truth on your application form?"; "Have you been in contact with a foreign intelligence agency?"), this is the test format commonly used in screening job applicants or vetting people for security clearances. It is estimated that a million people in the United States were subjected to polygraph testing in 1983. President Ronald Reagan's National Security Directive, due to take effect in April 1984, will require millions of federal employees and employees of civilian defence contractors to submit to such tests on demand or face "adverse consequences".

All anyone can determine from a polygraph chart is that the subject was more aroused or disturbed by one question than by another; one cannot tell why he was disturbed, or whether the question elicited guilt or fear or anger. Nor is it meaningful to compare Jones's reaction with Smith's response to the same question, since individual differences both in emotional and physiological lability are so great that a small response for one person may be a large response for another. Moreover, it is generally agreed that it is the question, rather than the subject's answer to the question, that determines the recorded response. In the relevant/irrelevant test, therefore, it must be assumed (1) that an innocent person will be no more disturbed by the accusatory relevant questions than by the innocuous irrelevant questions and (2), the corollary, that any relatively stronger response to a relevant question indicates deception rather than, say, embarrassment, fear or indignation.

A young engineering professor, engaged in secret research for the Central Intelligence Agency (CIA), was recently tested by a CIA polygrapher in connection with his security clearance. The question "Have you ever engaged in homosexual activity?" produced in him more physiological arousal than the interpolated irrelevant questions. It was concluded that this young scientist was a "closet" homosexual subject to blackmail and his clearance was withheld. It is possible that this examiner actually assumed that deception was the only reasonable explanation for the physiological disturbance evoked by this question. On the other hand, many polygraphers regard themselves as the real "lie detectors" and their understanding of the facts plus their interpersonal impressions are combined, according to unspecified rules, with whatever they think they can see in the charts in arriving at their diagnosis. Moreover, many polygraphers continue to believe, against all evidence, that certain patterns of reaction are specific evidence of lying; "stair-step" respiration, for example, or an increase in blood pressure in anticipation of a question, followed by a "relief response" after the question has been answered. A polygraph chart is noisy and complex; like the tea leaves at the bottom of a cup, it invites flights of interpretive fancy.

	Polygrapher's diagnosis			
Status of suspect	**Deceptive**	**Truthful**	**Total**	**Accuracy**
Guilty	98.1	19.9	118	83%
Innocent	38.2	50.8	89	57%
Accuracy*	72%	72%	20%	72%

Aggregated findings of the three credible field studies of polygraph accuracy[6,8,9] in which polygraph charts of 207 criminal suspects were scored independently by 14 polygraphers. Average accuracy on guilty suspects was 83%; however, 47% of innocent suspects were erroneously diagnosed as "deceptive".

*The accuracy of tests that are "failed" or "passed" depends on the proportion of liars in the group tested. Thus, if 800 of 1,000 persons tested are truthful, a test that is 72 per cent accurate overall will "fail" 144 liars and 224 truthful persons.

Polygraphic interrogation

Reacting to President Reagan's plans vastly to expand federal use of the polygraph test, the US Congress asked its Office of Technology Assessment (OTA) to examine the scientific status of this technique. OTA's report[3], published in November 1983, concluded that there is no scientific evidence at all concerning the validity of the type of test used in preemployment or periodic screening. To understand how, in the absence of such evidence, polygraphic screening has become a multi-million dollar industry in the United States, it is necessary to appreciate that the lie detector has been a part of American mythology for 50 years. Every citizen has heard of this device and assumes that it must work; why else would the Federal Bureau of Investigation (FBI) and the Pentagon use it?

Why would politicians and other celebrities, their veracity challenged, volunteer to take lie detector tests? Once established, such a myth feeds on itself. Refusal to submit is interpreted to mean that one has something to hide. As Richard Nixon remarked on the Oval Office tape of 14 July 1971, "Listen, I don't know anything about polygraphs and I don't know how accurate they are but I know they'll scare the hell out of people".

The control question test

Polygraph examiners, too, believe in the myth of the lie detector because they are generally insulated from discorroborative evidence. An examiner may give 1,000 tests a year and yet almost never discover, after having recorded his diagnosis, whether he was right or wrong. In the absence of corrective feedback, wishful thinking flourishes.

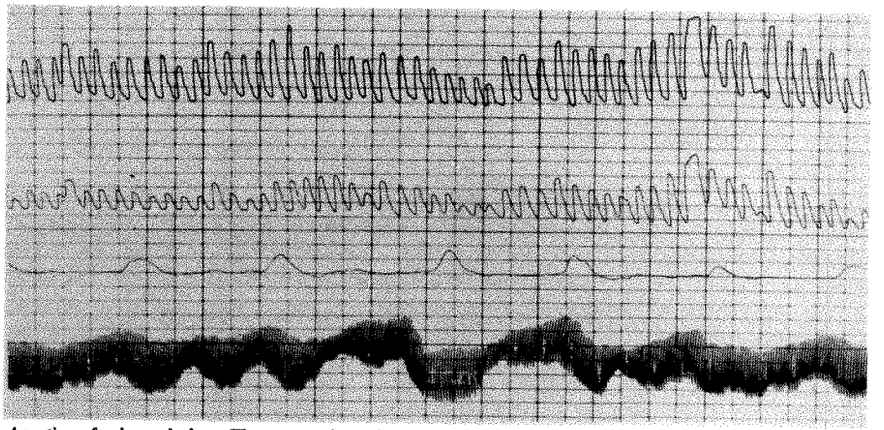
Yet, by the late 1940s, some perceptive polygraphers had come to realize that, "Did you take the $1,000?" may be a stronger stimulus than "Is your name John?" even for an innocent suspect. Therefore, a new test format was devised by the late John Reid, an attorney, who operated the Reid College for the Detection of Deception in Chicago. Reid added a third type of question, misleadingly known as "control" questions, to the standard list. Although it does not lend itself to the screening application, the control question test (CQT), in one form or another, has become the standard technique for use in specific issue situations, as in criminal investigation.

For a person suspected of Crime X, a genuine control question might be, "Did you commit Crime Y?", where Y and X are equally serious and where the examinee can be persuaded to believe that he is truly suspected of Crime Y although, in fact, the examiner knows that Crime Y is fictitious. Then the polygraphic reaction to the question about Crime Y will provide an estimate of how this subject should react to the question about Crime X, if he is also innocent of that crime. For a variety of obvious reasons, this type of control is seldom possible. Instead, the examiner tries to develop two or three "probable-lie control questions", questions referring to the examinee's past which he will answer deceptively out of embarrassment or a desire to make a good impression.

This curious concept can most easily be understood in terms of an example. A young mother in Hillsville, Virginia, was awakened at 3 a.m. one night last year by an intruder who, on threat of death to her and her child, proceeded with an elaborate sexual assault which, among other perversities, involved shaving her pubic hair. The local sheriff had read somewhere that this feature was characteristic of lesbian rape and the victim therefore was asked if her assailant had been a woman. In many US jurisdictions it is commonplace to require rape victims to submit to a polygraph test and, when this woman insisted that she had been raped by a man, she was referred for testing. Two of the "control" questions asked were: "Before the age of 15, do you remember playing with your sex organ?"; and "Between the ages of 15 and 25, did you ever have sex with a woman?" The examiner, employed by the state crime

bureau, had been trained at the highly regarded Backster school of polygraphy and had more than 10 years of experience. On the basis of that training and experience, he asumed that this woman's "No" answers to these questions were "probable lies". Therefore, he compared the strength of her physiological reaction to these "control" questions with her reaction to the relevant question, "Was the person who attacked you a woman?" Backster, whose methods are used by FBI and taught at the US Army Polygraph School, teaches that a subject will focus on the source of greatest threat. If he can be truthful in answering the relevant questions, then the examinee is expected to feel that his greatest jeopardy lies in the "fact" that his answers to the control questions are deceptive.

Since the Backster form of CQT is widely regarded as the state of the art of polygraph interrogation, it is appropriate to consider its assumptions with some care:



Assumption 1

The examiner will be able to invent several questions referring to the subject's past which the subject will answer deceptively. Is it reasonable to assume, in spite of her denials, that this rape victim practised masturbation before the age of 15 and that she subsequently had at least one homosexual experience? In 1982, in connection with a leak of information to the *Washington Post*, the chairman of the Joint Chiefs of Staff and the Secretary of the Army were given polygraph tests by Pentagon examiners. The questions used in those tests are not in the public domain, yet we can still ask ourselves whether it is reasonable to assume that those examiners were able to invent questions to which these high officials "probably lied".

Assumption 2

A subject who can answer the relevant question truthfully will be more disturbed by the "controls" than by the relevant questions. In the case of this rape victim, perhaps all one can say is that it is unreasonable to predict with any confidence which questions she might find more disturbing.

Floyd Fay, on the other hand, was confronted with a clearer choice[4]. Fay was arrested in Toledo in 1978 and charged with robbing and murdering an acquaintance who, before dying, had stated that the masked robber "looked like Buzz (Fay)". Fay was held without bond for two months while the police searched, in vain, for evidence tying him to the murder. Finally, the prosecutor offered to drop the charges if Fay passed a polygraph test, but required Fay to stipulate that the results should be admissible in court if the test indicated deception. Fay agreed, failed the test, failed a second test by a different examiner, was tried and convicted of aggravated murder and sentenced to life imprisonment. After more than two years, the real killers were caught; they confessed, exonerating Fay who was promptly released.

A section of polygraph chart. The top two channels record thoracic and abdominal breathing movements. The third pen records changes in the electrical conductance of the skin; the wave-like electrodermal responses are related to insensible sweating of the palms. The bottom trace is the "cardio" channel; the pen deflects with each heart beat and the entire tracing moves up and down with changes in blood pressure.

A relevant question in Fay's first test was "Did you shoot Fred?" A "control" question was, "Before the age of 25, did you ever think of hurting someone for revenge?" Because Fay's physiological response to the first question was, in the examiner's opinion, somewhat stronger than his reaction to the second, Fay was diagnosed as "deceptive". What the jury heard was that this examiner had many years of experience, that he had administered a standard control question polygraph test and that in his professional opinion Fay was deceptive in denying his guilt. Such is the strength of the myth of the lie detector that the jury had little difficulty in concluding "beyond reasonable doubt" that this man, who had no previous criminal record and against whom there was no credible evidence, was guilty of murder.

The two tests that Fay "failed" were typical examples of the CQT format which spokesmen for the polygraph industry claim to be accurate at least 95 per cent of the time. F. Lee Bailey, for example, a polygrapher before he became a defence lawyer, asserted recently on national television that, "Out of 100 tests, we expect 96 to be correct, three to be inconclusive and only one to be in error". To accept such a claim, we must be able to agree that an innocent person, accused of killing Fred, will be less disturbed by the question, "Did you shoot Fred?" than by the question, "Before the age of 25, did you ever think of hurting someone for revenge?" — in 96 cases out of 100.

Assumption 3

The third assumption of CQT is that guilty persons, who must answer the relevant questions deceptively, will show stronger reactions on the polygraph to the relevant than to the "control" questions. While this seems plausible, at least in comparison with the first two assumptions, it should not be accepted too readily. John Reid himself showed in 1947 that a sophisticated subject can artificially augment his natural response to a question by self-stimulation — by biting his tongue or pressing on a nail hidden in his shoe — and that the examiner cannot distinguish these augmented responses from normal ones. Thus, a person who can recognize the "control" questions as they are asked might "beat" the lie detector by augmenting his responses to these questions so that they are stronger than his natural responses to the relevant questions. Floyd Fay confirmed this idea while serving time in the London (Ohio) Correctional Facility. That prison routinely used polygraph tests to adjudicate charges against inmates of violating prison regulations. Having studied the literature on the polygraph, Fay decided to attempt his own experiment. By the time he was exonerated and released, Fay had managed to coach 27 inmates, all scheduled to take polygraph tests and all willing to confess to him that they were guilty; 23 of the 27 beat the lie detector.

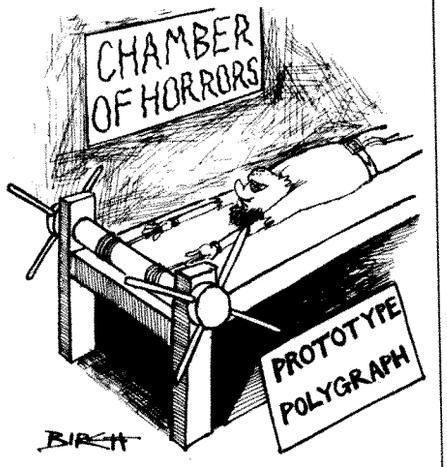
The evidence

The recent OTA report, which found no credible scientific evidence of the validity of R/I or screening tests, did find 10 field studies of the accuracy of CQT that it considered to be worthy of consideration. The earliest of these[5] compared results of tests administered to criminal suspects with the judgement of a panel of legal experts who later reviewed the dossier on each suspect. Because the polygraphers in this study based their conclusions on what they knew of the evidence and on their impressions of the suspects' demeanour during the interview, as well as on whatever they inferred from the charts, we cannot tell what contribution, if any, the actual polygraph results made to their performance. To assess the accuracy of the lie detector in real life, we must use tests given in real life situations (since we cannot simulate in the laboratory the emotional concerns of an actual criminal suspect) and we must then have the polygraph charts evaluated by a different examiner from the one who administered the test.

Another requirement is to find a criterion by which to identify those

suspects who were actually lying and those who were being truthful. Some individuals will confess their guilt at a later time so that we know they were deceptive on the polygraph. Such confessions often will clear another suspect whose tests are then verified as truthful. Finally, it is plainly improper for a polygrapher to select the tests to be re-scored, choosing only those examples that he did score or would have scored correctly. Several of the other studies considered by OTA appear to have violated this rule.

In one good study[6], for example, 109 successive suspects were tested by one examiner and then the charts were scored by a second polygrapher. A panel of five experts reviewed the final evidentiary files and excluded cases where they felt that the evidence did not permit a decision as to guilt. On the 51 cases where there was both a panel decision and a definite conclusion by the examiner, the average accuracy achieved was 72 per cent (against a 50 per cent chance expectancy). The polygrapher correctly labelled 98 per cent of the guilty suspects as deceptive, but he did this at the expense of the innocent suspects, 55 per cent of whom were also called deceptive. This study is one of the three extant that clearly meet the criteria specified above.



Subsequently, however, the guilt or innocence of 16 of the original 109 suspects was verified by confession and the polygrapher was shown to have been correct in 14 of these cases; he classified the other two as inconclusive. He then submitted these 16 charts to 25 other polygraphers for re-scoring, finding that those who used the same scoring system as he did scored these particular charts as he had done. This small study[7] provides evidence that polygraphers who use numerical scoring will tend to agree with one another, but it cannot be taken as evidence of the accuracy of CQT. The original study, from which these few charts were drawn, provides that evidence and it shows that CQT was wrong 28 per cent of the time overall and that it was biased against the truthful persons, more than half of whom were erroneously scored as deceptive.

Guilty knowledge test

A fundamentally different procedure for the polygraphic interrogation of criminal suspects attempts to detect not lying but the presence of guilty knowledge. In the rape case described earlier, the victim's twisted assailant did a variety of unusual things during the two hours or so that he spent with her. When she chanced to identify him on the street four months later, the memory of most of those acts would still have been with him. The police examiner might have conducted a polygraph test using questions like:

"The rapist in this case poured some sort of fluid between his victim's legs. If you are the man, you will remember what liquid it was. Just sit quietly now and repeat the names of these liquids. What liquid did the attacker pour between the victim's legs? Was it — (1) water? (2) beer? (3) nail polish? (4) urine? (5) perfume? (6) blood?".

Since people tend to respond most strongly to the first item in a series, the first alternative is never correct and never scored. An innocent person might react physiologically to each of the five scored alternatives but would have only about one chance in five of reacting most strongly to the correct alternative (nail polish, in this case). With 10 multiple-choice items of this type, an innocent person would have less than one chance in 10 million of reacting most strongly to all 10 correct alternatives in the absence of guilty knowledge. The guilty knowledge test (GKT), in laboratory experiments with simulated crimes, has repeatedly been found to detect most of the "guilty" suspects while clearing all of the innocent ones. In the absence of research on GKT under real life conditions, however, it would be rash to assume that it

can work equally well in actual criminal investigation. This research has not been attempted, partly because GKT is more difficult to implement than merely asking the suspect, "Did you do it?" and partly because polygraphers continue to believe in the myth of the lie detector. In the actual rape case, the same examiner who had concluded from testing the victim that her assailant was a woman also tested the man she later identified as the rapist. Not too surprisingly, this man was diagnosed as truthful.

Conclusions

The type of polygraph test used for screening job applicants (or federal employees requiring top secret security clearance) assumes that physiological reaction to accusatory questions is evidence of deception. There is no credible scientific evidence concerning the validity of such screening tests. Since highly socialized persons (religious, conscientious persons) tend to fail polygraph tests even when truthful, whereas poorly socialized persons — or sophisticated ones such as the KGB agents trained at their anti-polygraph school in Poland — tend to pass such tests even though lying[10], it is possible that the use of polygraph screening may produce results that actually are opposite to those intended.

The type of test used in criminal investigation or other specific issue situations also is predicated on implausible, even fantastic, assumptions. The three credible studies we have of the accuracy of these tests indicate that they are wrong nearly one-third of the time overall. The three studies show that an innocent person has almost a 50:50 chance of "failing" the lie detector. For this reason, when several persons are tested in respect to the same issue, polygraphers typically withhold judgement until all results are in. In the Pentagon case mentioned above, all 36 members of the Defense Resources Board were tested before one of them was identified as the culprit who leaked the information. Had the tests been scored independently, it is likely that a dozen or more "culprits" would have been identified. (The man who failed the polygraph, it turned out, was innocent; the real culprit apparently beat the lie detector. Even so, polygraphers here can claim 34/36 or 94 per cent accuracy!)

In the wake of the Geoffrey Prime spy case, and on the recommendation of the US security agencies, the British Government has decided to begin using the polygraph in vetting personnel of GCHQ and the Secret Service. Apart from damage done to the careers and reputations of innocent persons, this decision is likely to result in the loss to the government of some of its most conscientious civil servants, replacing them with the undersocialized types who easily pass polygraph tests. Because of the tendency to slightly more expensive but more effective security procedures, once polygraph testing has been introduced, this decision may well open the door to easy penetration of the security services by foreign agents trained to beat the polygraph.

The ever-expanding dependency on this pseudoscientific technique, in the face of both reason and evidence, implies an alarming degree of irrationality among decision makers in private industry, in the criminal justice system and even at the highest levels of government. □

IUPHAR 9TH INTERNATIONAL CONGRESS OF PHARMACOLOGY

29 JULY – 3 AUGUST 1984

LOCATION

Barbican Centre for Arts and Conferences, City of London

SCIENTIFIC PROGRAMME

The scientific programme will extend over five days and consist of symposia, invited lectures, pharmacological debates, an educational meeting and free communications, the latter as both oral and poster sessions. The symposia will consist of three simultaneous sessions morning and afternoon and each day there will be four invited lectures. A new feature of the International Conference is the pharmacological debates. In these the intention is to select topics on which there are clear differences in evidence or its interpretation and have the issue debated between protagonists of each view with sufficient opportunity for the audience to participate. In the educational meeting it is hoped to concentrate on the place of various forms of programmed learning in Pharmacology and the instrumentation available. Finally, there will be free communications and to the fullest extent possible authors will be allowed to select whether to give these as oral communications or as a poster.

PROCEEDINGS

The Congress Proceedings are being published by Macmillan Press and may be ordered in advance on the registration form or at the Congress.

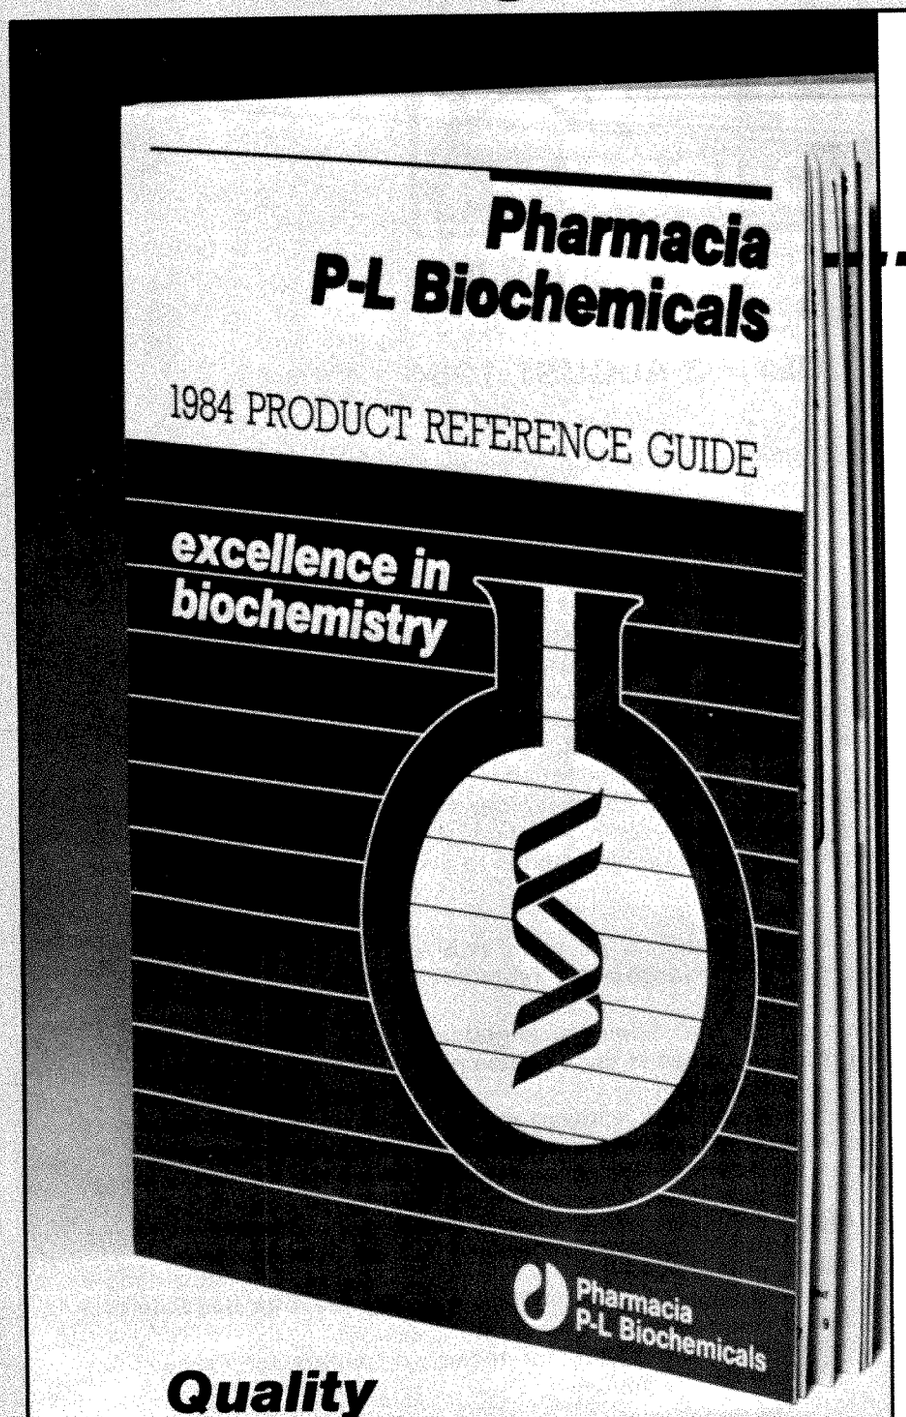
SOCIAL EVENTS

A full social programme is being arranged for delegates and accompanying guests. Details are given in the advance programme.

ACCOMMODATION

Accommodation has been reserved at advantageous rates in a number of hotels in various price categories and in student halls of residence. All accommodation is within easy travelling distance of the Barbican Centre.

DATES TO REMEMBER



1 May 1984	Deadline for college accommodation reservations.
18 May 1984	Deadline for receipt of registration at the standard fee (£150). There is a late fee after this date of a further £40. Deadline for receipt of papers for Proceedings volumes.

CONGRESS SECRETARIAT

Advance programmes, registration forms and abstract forms can be obtained from the Congress Secretariat:–

Congress Associates ICP
34 Stanford Road
London W8 5PZ
Telephone: 01 937 3163

There is only one product in this catalog...

...Quality

Actually, the Pharmacia P-L Biochemicals Product Reference Guide lists over 2000 products for biochemistry and molecular biology. The products range from restriction nucleases to coenzymes, from lipids to polynucleotides – but our most important product is the quality that goes into each biochemical that we make.

At Pharmacia P-L Biochemicals, we take our commitment to "excellence in biochemistry" seriously. We make our biochemicals with quality – we know no other way.

The 1984 Product Reference Guide from Pharmacia P-L Biochemicals

Abundant phase transitions

The bewildering variety in which phase transitions come is neatly illustrated in a collection of papers to be found in a single issue of a journal.

LAST year's final issue (on 26 December 1983) of *Physical Review Letters*, a journal which is no longer the exclusive preserve of high-energy physicists, contains half a dozen new twists in the understanding of phase transitions. What follows is merely a selection.

Simplest, perhaps because it is experimental, is a study of the properties of plutonium antimonide (chemical formula PuSb) which, among other things, has entailed the preparation of what are said to be the first "sizeable crystals" of any plutonium compounds — they come out at 8 mm^3. That in itself has been a substantial undertaking. Crystals of PuSb have been grown and embedded in a matrix of metallic copper (B.R. Cooper *et al. Phys. Rev. Lett.* **51**, 2418) by a four-cornered collaboration involving the Los Alamos National Laboratory, the University of West Virginia, ETH at Zurich and the Transuranium Institute at Karlsruhe (on account of its "unique handling and glove-box facilities"). The trick of surrounding the crystals with solid copper has the advantages of eliminating the toxicity hazard of the plutonium but also of preventing self-heating due to spontaneous fission.

The interest of PuSb is its magnetism. Plutonium is an element whose 5*f* shell is only partly filled with electrons. Indeed, the triply charged plutonium ions in the antimonide can have only five 5*f* electrons, whence the argument that the ion must have much in common with the electronic structure of the trivalent cerium ion Ce^{3+}, which has only one electron in the 4*f* shell.

This expectation seems to be borne out by experiment. PuSb, a cubic crystal, has markedly anisotropic properties which imply that the *f* electrons are not strictly localized on the atoms which contribute them to the lattice but, rather, are stretched out towards their nearest neighbours. Cooper *et al.* argue that this is an interesting case of hybridization between atomic and band electrons. Their discussion of the strength of the magnetic coupling between neighbouring plutonium atoms in the lattice is necessarily incomplete, but does not obscure the striking circumstance that PuSb is a ferromagnetic material below 75K and an antiferromagnetic material above, with a transition to disorder at 85K.

The obvious interest of the data now published is that they offer a way of testing different methods of approximation to interionic forces — and that there are more where these have come from. The antiferromagnetic phase of PuSb appears from neutron diffraction to have long-range order in which magnetic spins cancel out over a distance of about two lattice units.

This is comparable with the nature of the long-range order with respect to translation that occurs in the nematic phase of liquid crystals, where planar (and usually polar) molecules are spatially ordered. In the same issue of *Phys. Rev. Lett.* (p.2386), G. Grinstein and John Toner from the IBM Research Center at Yorktown Heights, New York, claim a remarkable prediction of a previously unrecognized property of those liquid crystals which can exist in the nematic phase and the two smectic phases *a* and *c*, the second of which involves both orientational and translation ordering of the planar molecules.

Which of the three phases will be assumed by any material will be a function of the only two adjustable parameters available — the temperature and the concentration of the material in its solvent. On such a plot, the pairwise phase boundaries should come together at a triple point, but so far this occurrence seems to have been unexplored. Grinstein and Toner argue that there cannot be a simple triple point but, rather, that there must be a fourth phase, a kind of hybrid between the nematic and smectic *c*.

Physically, what this implies is that the geometrical rearrangement of the planar molecules needed to accomplish the phase transition requires more than two steps to be taken in succession, but the point is established by means of A. C. Wilson's correspondence between lattice statistics and the renormalization theories that usually turn up in gauge field theories. None of this, of course, implies that the fourth phase will exist over a wide range of concentration or of temperature — indeed, the predicted effect may turn out to be too fleeting to be recognized.

The solidification of xenon adsorbed in gaseous form on a platinum surface has, however, been neatly observed by the scattering of helium atoms. Bene Prelsema, Laurens K. Verheij and George Comsa of the Low-Temperature and Vacuum Physics Division of the West German nuclear research centre at Julich point out (p.2410) that the cross-section for scattering helium atoms from molecules (for example CO) adsorbed on a metal surface can be very much larger than simple geometry suggests, perhaps as much as 125 $Å^2$. The result is that it is possible to use helium scattering as a measure of aggregation of adsorbed molecules for each possible density of coverage. Hitherto, attempts to measure condensation in adsorbed xenon have been unsuccessful, chiefly because of the need to work with surfaces which have been densely covered with adsorbed molecules. The helium atom technique works, but at the opposite end of the range, with as few as one in a thousand adsorption sites occupied. The result is what must have been hoped for. The transition from two-dimensional gas to two-dimensional solid occurs at lower coverage by adsorbed gas with decreasing temperature (at least down to that of liquid nitrogen). It has even been possible to infer the heat of vaporization of solid two-dimensional xenon (1.1 kcal per mole) and, because the densities of adsorbed gas at which crystallization occurs are indeed low, to explain why the phenomenon has not been previously observed. While xenon itself is of moderate interest, the helium scattering technique is likely to be widely used.

No fewer than three other types of phase transitions crop up in the same issue of *Phys. Rev. Lett.*, of which the transition known as commensurate-incommensurate is perhaps the simplest. A. H. Moudden, D. E. Moncton and J. D. Axe from the Brookhaven National Laboratory describe (p.2390) measurements of the behaviour of the dipolar molecular thiourea in strong electric fields using X rays to look for periodicity in a crystal lattice. At high field strength, greater than 1,000 volts per mm, thiourea crystals behave as if successful slab-like domains in which dipoles are oriented in one direction or the opposite in an alternating fashion along the field. The numbers suggest that under these conditions the slabs may be either 7 or 8 molecular planes thick. Decreasing the electric field allows 9-fold slabs to occur and also suggests how the relaxation to low field conditions may show hysteresis, as is observed.

What else? The process of wetting a solid surface is also a candidate for phase transition while the problem of percolation, in which free moving molecules thread their way through a tortuous lattice, clogging the system if there are too many of them, is dealt with for the first time on a lattice of fractal dimensions, no doubt simulating more accurately what may happen in the percolation of petroleum through, say, a reservoir rock.

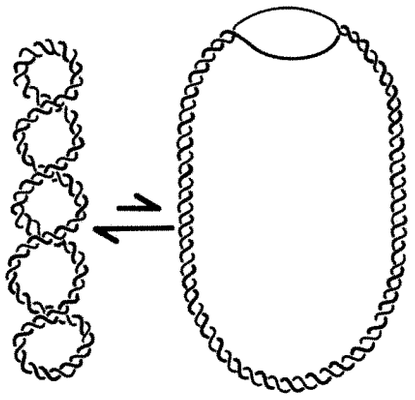
Genetics

DNA supercoiling and gene expression



from L. Mark Fisher

SUPERCOILING of DNA — coiling of the DNA helix axis — is now known to have a dramatic effect upon DNA replication, recombination and transcription in bacteria[1-3]. But how are bacteria able to regulate the supercoiling of their DNA? Recent work reveals that the degree of DNA supercoiling depends upon a dynamic balance between two mutually antagonistic enzyme activities: DNA gyrase which supercoils DNA, and DNA topoisomerase I and perhaps other enzymes which remove supercoils. Intriguingly, expression of the genes for one of these enzymes — DNA gyrase — appears to be itself regulated by DNA supercoiling[4,5].

Circular chromosomal and extrachromosomal DNA is actively maintained in a negatively supertwisted state by the ATP-dependent bacterial enzyme DNA gyrase. When gyrase activity is blocked by chemical or genetic means, relaxation of cellular DNA rapidly ensues with pleiotropic biological effects, including the halting of replication[2,3]. The coexistence in *Escherichia coli* of both gyrase and DNA-relaxing activity, predominantly DNA topoisomerase I (omega protein), suggests that both these competing activities may play a part in determining the cellular level of DNA supercoiling. Evidence to support this proposal has come from a series of elegant experiments made possible by the localization of the structural gene for topoisomerase I (*topA*) and the isolation of *E.coli* strains carrying mutations in this gene[6,7].

TopA maps to a region of the chromosome near *cysB* and is not closely linked to either *gyrA* or *gyrB*, which encode the gyrase A and B subunits. Point mutations in the *topA* gene of *E.coli* and their effects on DNA supercoiling have recently been studied in some detail[6,8,9]. When a strain bearing the nonsense mutation *top10* was examined, a level of DNA supercoiling higher than that of the isogenic wild-type strain was found. As the *top10* strain produces only low levels of topoisomerase I activity the simplest conclusion is that topoisomerase I acts in removing DNA supercoils *in vivo*. Deleting the entire *topA* gene leads, however, to an apparently contradictory result — the degree of DNA supercoiling is lower than that of the isogenic Top A$^+$ counterpart[9].

This paradox was resolved with the discovery that deletion of the *E.coli topA* gene is accompanied by the acquisition of a secondary mutation, closely linked to *gyrA* in one strain and to *gyrB* in another strain[8,9]. The respective gyrase A and B subunits purified from these strains are partly defective and are less efficient in promoting DNA supercoiling than wild-type subunits[4]. Apparently, too much supercoiling caused by a total absence of topoisomerase I is as deleterious as too little. Compensation for a lack of topoisomerase I activity is achieved by spontaneous mutations that reduce the supercoiling activity of gyrase. Thus, selective pressure exists to maintain an intermediate biologically acceptable degree of supercoiling.

Underwound circular duplex DNA (right) forms negative supercoils (left). DNA in the form of a closed circle with about one helical turn for every ten base pairs — the same pitch as linear duplex DNA in the B configuration — is said to be 'relaxed'. If the two strands of the duplex circle are intertwined fewer (or more) times than in the relaxed circle, the DNA minimizes its departure from the energetically favoured configuration by coiling about its axis, as in the figure. By convention, the supercoils formed by underwound DNA are referred to as 'negative' and those by overwound DNA as 'positive' (see *News and Views* **294**, 607; 1981).

How is the degree of supertwisting regulated in wild-type cells? Experiments by Gellert, Menzel and co-workers demonstrate that synthesis of gyrase is itself controlled by DNA supercoiling[4,5]. First, they carried out two experiments which showed that gyrase synthesis is activated by conditions that lower gyrase activity. Using antibodies raised against purified gyrase A and gyrase B proteins they measured the relative rates of synthesis of these proteins in various conditions. Treatment of *E.coli* with either of the gyrase inhibitors novobiocin or coumermycin, at concentrations known to induce relaxation of chromosomal DNA, led to a 10-fold increase in the rate of gyrase A and gyrase B synthesis. The time course of gyrase induction closely follows that observed for chromosomal DNA relaxation promoted by the inhibitor. Next, a strain carrying two mutations in *gyrB*, one conferring temperature sensitivity to growth, the other coumermycin resistance, were shown to have normal levels of gyrase A and B proteins when challenged with coumermycin. A shift to the non-permissive temperature, however, resulted in increased synthesis of both gyrase A and B subunits when compared with the isogenic *gyr B*$^+$ strain.

To confirm that DNA relaxation is the cause of gyrase induction, cloned *gyrA* and *gyrB* genes contained in plasmids were used to programme a cell-free protein synthesis system. The *gyrB* plasmid maintained in a relaxed state by the inclusion of novobiocin (to inhibit endogenous gyrase in the extract) produced up to 100 times more gyrase B protein than the plasmid in its supercoiled conformation. Stimulation of gyrase B synthesis was also observed in the absence of gyrase inhibitors when purified topoisomerase I from *E.coli* or HeLa cells was added to the system. Similar effects were seen in experiments using the *gyrA*-containing plasmid. These results show that gyrase synthesis is promoted by a relaxed DNA template and render unlikely the formal possibility that gyrase might regulate its own synthesis by binding to putative repressor sequences on DNA.

It is interesting that both the *E.coli* and the HeLa topoisomerase I enzymes act as positive effectors of gyrase synthesis. The fact that a eukaryotic relaxing enzyme can stimulate gyrase synthesis argues that these enzymes exert their effects by relaxing the DNA template rather than by binding to regulatory sequences on DNA. What controls the expression of topoisomerase I is not yet known although the recent cloning and analysis of the *topA* gene by Wang and colleagues should allow progress to be quickly made[10]. As yet, the possibility remains open that other DNA-relaxing enzymes isolated from *E.coli*, for instance topoisomerase II' (refs 11, 12), or topoisomerase III[13], may operate in concert with gyrase and topoisomerase I.

GyrA and *gyrB* belong to an emerging class of genes whose expression is dependent on DNA conformation[14].

Promoters that are activated by DNA supercoiling have already been identified and include those for catabolite-sensitive genes — the maltose operons, the lactose and galactose operons and the tryptophanase gene[15]. The mechanism by which DNA supercoiling enhances transcription from these promoters is not well understood. What is clear, however, is that RNA polymerase unwinds DNA on binding to the promoter — a process which should occur more easily on negatively supercoiled DNA as it is already partially unwound[16]. Why then is gyrase synthesis activated by a relaxed rather than a negatively supercoiled DNA template? At present this problem is unresolved although preliminary evidence again suggests that control is exercised at the level of RNA transcription[4]. Structural and functional analysis of gyrase genes and their promoters should help clarify how DNA supertwisting differentially affects gene expression. □

Science journals

Cryptozoology

from Robert M. May

OF the 79 *News and Views* pieces I have written over the past ten years, the one attracting far and away the most attention outside the ranks of *Nature* readers was a brief *jeu d'esprit* on 'The ecology of dragons' (*Nature* **264**, 16; 1976). This article was picked up by United Press International, and resulted in telephone calls from radio stations and newspapers in most English-speaking countries, offers to appear in three television shows and an invitation to write a coffee-table book about dragons. Needless to say, none of my other *News and Views* articles has produced anything approaching this reaction. The dragon article differs from the others only in that it deals with the unreal and fanciful, rather than with the real wonders that actually exist in the natural world. To generalize recklessly and gloomily, I think this isolated experience reflects a tendency on the part of the media — and maybe the public — to prefer meretricious marvels to real ones.

Be all this as it may, it is consistent with the fact that, of the plethora of new journals established in 1982–1983 (see the 6–13 October 1983 issue of *Nature*), *Cryptozoology* was the only one reviewed in *Newsweek*. *Cryptozoology* is the official journal of the International Society of Cryptozoology, whose president, Bernard Heuvelmans, defines the subject as "the science of 'hidden' animals". The first and to date only volume of the journal runs to 100 pages embracing articles, research reports, field reports and book reviews. By a rough count, 29 pages deal with 'wildmen' of one kind or another (such as 'Sasquatch' or 'bigfoot' in the Pacific Northwest and 'yeti' in China), 7 pages with mermaids in Papua New Guinea, 33 pages with the mysterious entities in Loch Ness and Lake Champlain, 16 pages with the putative sauropods (Mokele-Mbembe) of the Central African swamp-forest, and 15 pages with general definition and defense of cryptozoology as a legitimate subject for research. Clearly, if you want to be an interesting cryptobeast, you are well advised to be a large vertebrate, and preferably human-like or dinosaur-like.

More than half the pages devoted to human-like creatures are reviews of five books. These books appear to deal mainly with second- and third-hand anecdotes; it seems generally agreed that the hard evidence — photographs, tapes, casts of footprints — is fraudulent. An article by Guoxing on 'The status of wildman research in China' gives an earnest account of available reports, and speculates on whether the Chinese wildmen are surviving descendants of *Ramapithecus, Australopithecus* or possibly *Gigantopithecus*. With commendable honesty, the article concludes "it should be emphasized that many of the participants in Wildman research in China are professional scientific workers. At the same time, however, it has to be admitted that most of them are not well trained in faunal ecology, primatology, vertebrate paleontology, paleoanthropology, physical anthropology and other disciplines concerned with this topic". Wagner recounts tales told him by New Guinea natives about the mermaid-like *ri*, and comes to three conclusions: "they are certainly not dugongs" (it is sometimes suggested that manatees or dugongs gave rise to sailors' stories about mermaids); the reports are more substantial than the "inventories of rather fanciful 'bush' creatures" familiar to anthropologists working in New Guinea; and the reports "strongly suggest that some such creature exists, and that it remains unknown to science".

The papers on dinosaur-like creatures are, on the whole, less silly. A research report by LeBlond employs a photograph of the 'Lake Champlain monster' taken by Mansi in 1977, and uses standard results relating the appearance of the sea surface to wind speed, and thence to the length of wind waves, to estimate that the length of the 'monster' visible in the photograph is in the range 5–17 m. The evidence reviewed in other articles in *Cryptozoology* and in the pages of *Nature* over the past few years suggests that large objects of some kind (logs look like the best guess to me) are present in deep lakes such as Loch Ness or Lake Champlain, and LeBlond's elegant estimate of the physical dimension of one such object is useful.

Mackal, Greenwell and Wilkinson recount persistent reports of Mokele-Mbembe, a large creature with a long flexible neck and a tail like an alligator's, which inhabits the 60,000 square mile Likouala swamps in the remoter parts of the People's Republic of the Congo. These investigators recorded stories from the native inhabitants, including one of a hunter who had tracked a creature that left a path of grass flattened as if by a great tail, and positive reactions to photographs of sauropods. The reports also suggested that the apple-size fruit of the molombo (a tropical vine found in Africa) were the main diet of the Mokele-Mbembe. A separate paper by Weber, Berry and Greenwell therefore analyses the nutrient content of these fruit, and compares it with the nutrient requirements of typical large mammals, to conclude that molombo fruit alone could not sustain the Mokele-Mbembe. Mackal and his collaborators sensibly conclude that "our expedition found no compelling evidence that Mokele-Mbembe exists", although they append the usual appeal for further investigation.

Many people feel that the correct response from a scientist to the kind of enterprise this journal represents should be one of friendly, even encouraging, tolerance. At very least, I am persuaded such may be an expedient image to project. We would be ill-served if everyone studied safe subjects. But, in truth, my reaction to *Cryptozoology* is regret for the money libraries will waste on acquiring the journal (if only as a curiosity) and regret for the dissipated efforts that could be directed more productively to studying some of the species of tropical plants, insects and other organisms that may be going extinct at a faster rate than they are being classified. Even on its own Alice-Through-The-Looking-Glass terms, the journal *Cryptozoology* is marked by a rather arbitrary focus on only two groups — human-like and dinosaur-like — from the full cryptozoological spectrum of animals that may or may not exist; this spectrum is catalogued by Cohen in *The Encyclopedia of Monsters* (Dodd, New York, 1983). Some of the omissions are understandable: for instance, the lack of work on the unicorn is undoubtedly because these beasts are fairly generally agreed to have been hunted to extinction, a process made easier by virtue of their maladaptive attraction to virgins. Less understandable — especially to an antipodean — is the absence of any work on the bunyip, a particularly engaging but elusive member of the Australian cryptofauna. □

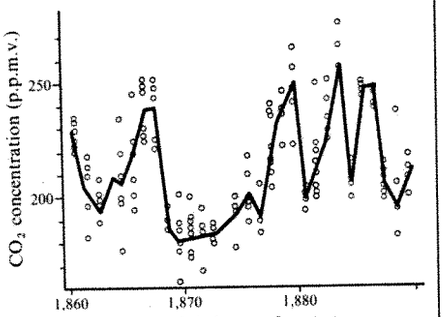
Carbon cycle

New data upset ice age theories



from Philip Campbell

"It was the best of times, it was the worst of times... it was the epoch of belief, it was the epoch of incredulity..."

AT the risk of over-dramatization, the opening lines of Dickens' *A Tale of Two Cities* reflect something of a recent meeting* devoted to the carbon cycle. Little of the meeting dealt with the effects of fossil fuels, the participants encountering enough problems and surprises from the natural cycle before it was perturbed by man. In particular, they were confronted with natural rates of change in atmospheric CO_2 concentrations much faster than previously measured, new data from deep-sea cores indicating that CO_2 variations precede changes in the extent of ice sheets (contrary to prevailing ideas), and theoretical results suggesting that atmospheric CO_2 was to a significant extent responsible for the warmth of Cretaceous climate.

A year or two ago, ice cores yielded the surprising result that at the end of the ice age, between 15,000 and 10,000 yr ago, the atmospheric CO_2 abundance climbed from about 210 to about 280 parts per million by volume(p.p.m.v.) in only a few thousand years[1,2]. W.S. Broecker[3] pointed out that over time scales shorter than the 180,000-yr residence time of CO_2 in the atmosphere and oceans, atmospheric CO_2 is controlled by the physical, biological and chemical state of the oceans. Thus such a 'rapid' increase of 70 p.p.m.v. would seem to have required an unusual perturbation to this system. Broecker suggested that detritus from surface organisms, containing organic carbon and phosphate, was deposited on the continental shelves as they were submerged following the melting of ice sheets. This reduced the phosphate/carbon ratio in the oceans and, phosphate being a limiting nutrient, the fixation rate of carbon by marine photosynthesis would have decreased. In this way the CO_2 concentration in ocean surface water, and hence the atmospheric CO_2 content, would have increased by the amount and in the time scale revealed by the ice cores.

A number of results presented at the conference were consistent with this model. For instance, one of its predictions is that, as a result of the removal of organic carbon from the ocean into shelf sediments, the deeper ocean would have become less prone to dissolve carbonate sediments, leading to enhanced preservation of $CaCO_3$. L.C. Peterson and W.L. Prell (Brown University, Rhode Island) sampled a series of deep-sea piston cores raised from the eastern flank of the Ninety-East Ridge in the east Indian Ocean. The depth range over the flank from 2.9 to 4.4 km encompasses today's lysocline, the oceanic boundary below which foraminiferal tests, or shells, will dissolve. Over the 700,000 yr record, both $^{18}O/^{16}O$ isotope ratios — interpreted as a record of global ice volume — and the proportion of carbonate revealed clear periodicities of 100,000, 40,000 and 19–23,000 yr. According to the now-respected Milankovich theory, ice ages are driven at these periodicities by changes, respectively, in the eccentricity of the Earth's orbit, the tilt and the precession of the Earth's rotation axis. More to the point, the amount of $CaCO_3$ present in the cores was a maximum when ice volume was decreasing most rapidly and was a minimum when the ice sheets were expanding at their quickest. This specific relationship concurs with a recent numerical model[4] based on the phosphate-extraction hypothesis. A correlation of sea level falls and increased carbonate dissolution in the Canary Basin, North Atlantic, was also reported by J.T. Crowley (NSF Climate Program, Washington) using a similar experimental approach.

Atmospheric CO_2 variations from the Dye 3 ice core.

The theoretical impetus provided by Broecker's model was illustrated by several computer models of the ocean–atmosphere carbon cycle. F. Knox and M. McElroy (Harvard University) and J.R. Toggweiler and J.L. Sarmiento (Princeton University) described similar models in which the atmosphere, the intermediate/deep ocean, low-latitude and high-latitude shallow ocean reservoirs are represented by distinct boxes, linked by appropriate carbon fluxes. The purposes of these models is to investigate the roles of high-latitude nutrients and of ocean circulation rates in controlling atmospheric CO_2 levels, bearing in mind that restricted areas of the ocean surface, such as the Antarctic upwelling regions where productivity in surface waters is high, can have a considerable effect on the carbon chemistry of the entire deep oceans and the atmosphere. Both models confirm that an increase in high-latitude surface nutrients is associated with enhanced atmospheric CO_2 levels, demonstrating that changes in large-scale (thermohaline) circulation and in high-latitude surface water productivity (caused, for instance, by changes in light levels) could have a crucial role. A 1,000 yr response-time of the predicted changes is imposed by the circulation time of the deep ocean.

All the results described so far have been consistent with and/or stimulated by the phosphate-extraction hypothesis. It is intriguing, to say the least, that two papers were presented that between them — as Broecker (Lamont-Doherty Geological Observatory, New York) himself pointed out — seem to demolish shelf deposition models.

The first challenge has come from ice cores. B. Stauffer, U. Siegenthaler and H. Oeschger (University of Bern) reported measurements of past CO_2 concentrations from the Dye 3 site in Greenland — a record spanning the period 25,000–40,000 yr ago. Four sharp peaks in CO_2, reaching levels of 250 p.p.m.v. from a 'background' of 200 p.p.m.v., occurred during the last ice age (see the figure). The magnitude of the changes are of the order which the phosphate-extraction model seeks to explain, but the excursions appear to have occurred within a hundred years or so — ten times faster than can possibly be explained by shelf deposition. The excursions are well correlated with oxygen isotope changes, as are accompanying variations in trace chemicals Cl^-, NO_3^- and SO_4^{2-} (R.C. Finkel and C.C. Langway, SUNY, Buffalo). Stauffer *et al.* proposed that climate behaved as a bistable oscillator during the last glaciation. If the rapid CO_2 variations are also found in Antarctic ice cores, then the idea that CO_2 acts as an interhemispheric climatic amplifier will be greatly strengthened.

T. Wenk, Siegenthaler and Oeschger (University of Bern) described a box model constructed on identical principles to the two already discussed to explain these rapid variations. They reported that a 50% reduction from present-day conditions in the exchange flux between high-latitude (Antarctic) surface and deep waters results in a decrease in atmospheric CO_2 levels of 50 p.p.m.v., an effect which is enhanced if the large-scale circulation is increased. These authors maintain that changes in surface circulation could account for rapid CO_2 variation, although this view was challenged by other box-modellers. The role of deep-ocean circulation as an inhibitor of such rapid variations was left unresolved; all three box models were steady-state calculations, and models of the transient responses are now required.

A second nail for the coffin of shelf-deposition models was provided by N. Shackleton (University of Cambridge) and N.G. Pisias (Oregon State University), who presented high-resolution oxygen and carbon isotope records from an equatorial Pacific deep-sea core. Because marine

*The Chapman Conference on 'Natural variations in carbon dioxide and the carbon cycle' was held in Tarpon Springs, Florida on 9–13 January.

0028-0836/84/080688-01$01.00

photosynthesis preferentially extracts ^{12}C from surface waters, the $^{13}C/^{12}C$ ratio in foraminifera can indicate changes in the oceanic carbon reservoirs. (It is essential to distinguish between this effect and that of deep-ocean circulation, which causes a progressive isotopic lightening of dissolved CO_2 in deep waters as they circulate through the rain of organic detritus from surface regions. Several talks at the meeting highlighted different ways of tackling this problem.

Broecker had already showed[3] that the difference in carbon isotope ratios in surface and deep waters varies with atmospheric CO_2 levels. Interpreting planktonic and benthic foraminiferal isotope ratios in this manner, Shackleton and Pisias provided a record of ice volume and atmospheric CO_2 over a 340,000 yr period. The Milankovich frequencies were clearly present with the CO_2 record having a stronger high-frequency content — consistent, perhaps, with the ice-core data. Both ice volume and CO_2 changes lag the orbital (Milankovich) changes but, most significantly, the changes in CO_2 lead those in ice-volume by, on average, 2.5×10^3 yr. This result is completely at odds with shelf deposition models (which predict that sea level changes lead CO_2 changes) and the authors concluded that variations in atmospheric CO_2 are part of the direct forcing of ice ages. They argued that changes in the ocean nutrient cycling and in ocean circulation must lie at the root of the CO_2 changes. However, the field is now open for more specific explanations.

This report has so far been restricted to variations in the carbon cycle over time scales of tens of thousands of years or less. But the Florida meeting covered the entire gamut of time scales up to 10^9 yr; those of 10^7–10^8yr, associated with the Cretaceous and Cenozoic eras, were the subject of particularly lively discussion.

A provocative interpretation of South Atlantic deep-sea carbon isotope data from the last 75 Myr was presented by N. Shackleton. He used the ^{13}C record in bulk sediments to deduce changes in the partitioning between limestone and organic carbon and hence in the global organic carbon reservoir. According to his data, the amount of organic carbon stored in sediments 70 Myr ago exceeded that in today's oceans by about 10^{19} moles. Shackleton concluded that oxygen in the atmosphere must have been correspondingly enhanced over the present-day content by 20%; the dissolved oxygen concentration would have been similar to today's because of the reduced solubility in the warmer ocean waters at that time. H.D. Holland (Harvard University) and R.M. Garrels (University of South Florida) suggested, however, that the excess oxygen would have been accommodated by SO_4 in the oceans, and a debate ensued, hingeing on the differences between the residence time of SO_4 in the ocean and the characteristic time scales within Shackleton's data. J.R. Herring (US Geological Survey, Lakewood) maintained that the putative enhancement in oxygen is rebutted by the absence of a significant increase in charcoal fragments or other sedimentary signatures of natural plant burning.

Over the 100 Myr time scale, geological processes provide significant contributions to the carbon cycle. In particular, the balance between weathering, by which CO_2 is removed from the atmosphere and stored as carbonate, and metamorphism (in which the process is reversed) has a significant effect on atmospheric CO_2. Recently a geochemical box model was published[5] in which the oceans, the atmosphere, calcite, dolomite and Ca–Mg silicate reservoirs were linked by the chemical reactions of weathering and metamorphism. The novel aspect of the model lay in its treatment of the chemical rate constants. Those connected with weathering, for instance, were parameterized in terms of atmospheric CO_2 levels.

A number of problems and uncertainties associated with the published model were raised at the conference. However, these were trumped by its instigators, A. Lasaga, R. Berner and R. Garrels (Pennsylvania State, Yale and South Florida University respectively), who presented an extended model in which organic carbon, evaporates and pyrite reservoirs were incorporated. One of the model's central conclusions eventually remained unchallenged: that in the Cretaceous, 100 Myr ago, the amount of CO_2 in the atmosphere was at least four, and maybe over ten times as great as today's, with average temperatures correspondingly elevated.

This conclusion was supported by S. Schneider, S. Thompson and E.J. Barron (National Center for Atmospheric Research). Using a three-dimensional atmospheric circulation model in which the continental geography resembles that of Cretaceous times, they found that no matter how oceanic circulation is varied, winter temperatures in high-latitude continental interiors remain near or below freezing, a situation belied by palaeobotanical evidence. They suggest that elevated CO_2 concentrations might have been the missing factor that produced the higher temperatures of that era.

These models and much of the rest of the work described in this report reflect one of the major themes to come out of the conference. As one of its organizers, E. Sundquist (US Geological Survey, Reston) emphasized, climate and the carbon cycle appear to have been more tightly linked than previously thought. □

Evolutionary biology

When deviants are favoured: evolution of sex determination

from Paul H. Harvey and Linda Partridge

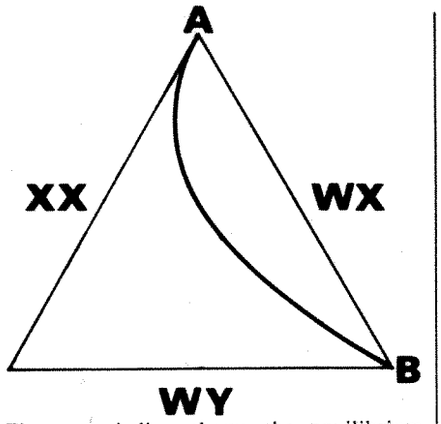
A NEW book from J.J. Bull[1] makes a fresh attempt at explaining the evolution of mechanisms that determine sex. What makes the problem a difficult one is the bewildering variety of sex-determining mechanisms found in the animal and plant kingdoms, and the seemingly chaotic way in which they are distributed among taxa. Even in species with separate sexes, male heterogamety (XY male, XX female) can be found in such diverse taxa as mammals, fruit flies and some vines, while female heterogamety (ZW female, ZZ male) occurs in birds, schistosomes and strawberries. Haplo-diploidy (males develop from unfertilized eggs and are therefore haploid, females from fertilized eggs and are diploid) is thought to have evolved at least eight[2] and probably more than twelve[1] times among insects, mites and rotifers. Sex may even be environmentally determined, as in many reptiles, a marine fish, an echiuroid worm, a crustacean parasite of fish gills, some nematodes and at least one species of amphipod.

Bull documents much of the diversity of sex-determining mechanisms but his book differs from previous accounts because it specifically addresses the question of how one type of sex determination can evolve into another. His approach is to consider what combination of selective forces and historical constraints have resulted in the evolutionary changes observed, these being only a limited subset of the theoretically possible transitions. The application of this approach across a broad taxonomic range allows him to draw some very general conclusions about the parts played by selection and by evolutionary constraints.

Haplo-diploidy

Haplo-diploidy appears from its taxonomic distribution to have often evolved from an ancestral diploid condition, as does a functionally equivalent system — paternal genome loss — where males are produced from fertilized eggs which transmit only the maternally derived part of their genome to their offspring. What selective forces are responsible for the evolution of these systems? Hartl and Brown[3] and Bull[1,4] suggest that an allele

© 1984 Macmillan Journals Ltd



causing a female to produce haploid eggs that will develop into sons will increase in frequency in her grandchildren because haploid sons transmit maternal alleles to all their offspring whereas diploid sons transmit maternal alleles to only half their offspring. As long as the haploid sons leave more than one-half as many offspring as the diploid sons, haplo-diploidy will spread.

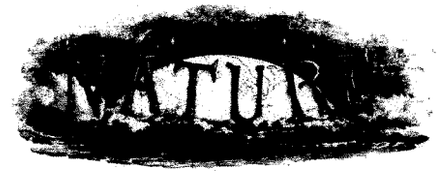
But this argument applies equally well to male and female parents — any genetic device in a parent that causes offspring to transmit only alleles from that parent should be favoured. Why, then, is it always the maternal genome that is transmitted? And why is the maternal genome always transmitted by sons rather than daughters? The first question is difficult to answer: selective transmission of the paternal genome could, in theory, be effected via haploid embryos that develop from sperm (which is improbable) or from a fertilized egg that lost its maternal genome. It is not yet clear why the latter mechanism has never evolved (as far as we know), partly because the mechanism of paternal genome loss is not well understood. Perhaps females are in a position to resist male-derived mutants that cause maternal genome loss. The reason that only sons transmit the maternal genome is probably related to the disadvantages of asexual inheritance[5-7]. Transmission by daughters would mean that male-derived alleles would never be transmitted to females and would cause asexual inheritance in the female line. Finally, haplo-diploidy could only arise from a diploid species with a sex-determining mechanism such that aberrant haploid individuals develop into males[1].

Genetic and environmentally determined sex

There have been several evolutionary transitions between genetic and environmentally determined sex. Environmental sex determination is likely to be favoured in a patchy environment where different patches affect the fitnesses of each sex differently, but where parent and offspring have little or no control over the type of patch in which the offspring develop[8].

Take the case of mermithid nematode worms, for example. Free-living adult worms lay eggs in larval insect hosts: the worms hatch and grow to a size determined by the richness of the food source, which is itself determined by the density of the worms and the nutritional status of the host. But female fitness increases with size more than does male fitness and, as a result, selection has operated so that worms developing at high density or in a poorly fed host tend to become males, while those developing at low density or in a well fed host become females[9,10]. In the case of these worms, offspring cannot choose the type of host in which they develop and mothers laying eggs may not be able to detect whether the potential host has already been parasitized by other mermithid nematodes. The two conditions

The curved line shows the equilibrium frequencies of the three different genotypes of female platyfish (see text). When the perpendicular distances from the three axes to any point on the line are scaled so that they sum to unity, their lengths give the frequencies of the three genotypes. The points labelled A and B represent extremes with female heterogamety (WY female, YY male) and male heterogamety (XY male, XX female). Populations at all other points on the line of equilibria contain three female genotypes (WY, XX, WX) and two male genotypes (YY, XY). (Refs 1, 17.)



of absence of patch choice and differential fitness of the two sexes thus apply. The model also seems to hold in other cases[11-13], and some preliminary data suggest it may well be relevant to environmental sex determination in reptiles[14,15].

Under what conditions can genes for sex determination invade species with environmentally determined sex? The theory given above suggests that changes in relative fitness of the two sexes must be fairly consistently associated with particular patch types for environmentally determined sex to be favoured. In the wild, this condition will not always hold. If mermithid nematode population density were to vary between seasons or if host nutritional condition also changed dramatically between seasons, then, under pure environmental sex determination, some seasons might produce very high proportions of males and others would produce excess females. This would result in fluctuating fitnesses for individuals of each sex and, in such conditions, genotypic sex determination can invade[1]. (Could some dinosaurs have gone extinct because their sexes were environmentally determined? A sudden change in climate without an appropriate genetic response could provide the conditions for producing populations consisting totally of frustrated males, or females if you will.)

Male and female heterogamety

Although there are conditions in which one sex-determining mechanism can invade a population with an alternative method of sex determination, this does not necessarily mean that the new mechanism will completely replace the old. Indeed, it is possible for two or more sex-determining mechanisms (or sex factors) to be maintained at equilibrium in the same population. Sometimes, instead of a single equilibrium, there is a continuous set of stable equilibria which can be described graphically by lines of 'neutral equilibria' along which any point describes a combination of equilibrium sex factor frequencies. When populations lie on such a line, there is a prospect for indeterminate evolution — genetic drift can carry small populations along the line of neutral equilibria. The commonest mechanisms of sex determination in animals — male and female heterogamety — could evolve from one another in this way.

An example is provided by a tropical poeciliid fish, the platyfish (*Xiphophorus maculatus*), a favourite among aquarium fanciers, of which the earliest captive individuals proved to have female heterogamety while later collections had male heterogamety. It turns out that natural populations are polymorphic for three sex factors (W, X and Y) which could occur in six different combinations: XY, YY, XX, WX, WY and WW. The XY and YY genotypes usually develop as males and XX, WX and WY become females[16]; WW genotypes do not in fact occur because male gametes can never bear W factors. Assuming that fitnesses of the different genotypes are the same within each sex, their equilibrium frequencies can be calculated[17] (see the figure). At one

100 years ago

PROF. HULL, who has returned with his party, brings with him, it is stated, materials for the construction of a geological map of the Holy Land very much in advance of anything which could hitherto be attempted. He is reported to have traced the ancient margin of the Gulfs of Suez and Akaba to a height of 200 feet above their present levels, so that, according to Prof. Hull, the whole country has been submerged to that extent, and has been gradually rising. As one result of this rise, the Professor is of opinion that at the time of the Exodus there was a continuous connection of the Mediterranean and the Red Sea. As regards the Dead Sea, Prof. Hull believes he has discovered that it formerly stood at an elevation of 1400 feet above its present level — that is to say, 150 feet above the level of the Mediterranean. He believes he has also found evidences of a chain of ancient lakes in the Sinaitic district, and of another chain in the centre of the Wady Arabah, not far from the watershed. The great line of the depression of the Wady Arabah and the Jordan Valley has been traced to a distance of more than a hundred miles. The materials for working out a complete theory of the origin of this remarkable depression are stated to be now available. Prof. Hull has in hand, besides his scientific report, a popular account of his journey, which will first appear in the *Transactions* of the society.

extreme, X factors disappear from the population and female heterogamety (WY females, YY males) describes the system (point A). At the other extreme the W factor disappears, leaving a system of male heterogamety (XX females, XY males; point B). Platyfish populations can thus be viewed as in transitional states between systems of either male or female heterogamety. Environmental change that differently affects the fitnesses of the various genotypes within each sex could trigger transitions between the two modes of sex determination.

Hermaphroditism to heterogamety

Just why it is that male heterogamety is common and female heterogamety rare[18–20] among dioecious plants (those having separate sexes) has been explained elegantly by Charlesworth and Charlesworth[21]. Their argument necessarily supposes that dioecious plants evolved from hermaphrodite ancestors through an intermediate stage, of either gynodioecy (females and hermaphrodites) or androdioecy (males and hermaphrodites). A transition from hermaphroditism to either gynodioecy or androdioecy may be favoured if loss of one sexual function can be balanced by increased resource allocation to the other, and if the single-sex individuals avoid self-pollination with its attendant inbreeding depression. But pollen from the male plant of an androdioecious species may be at a disadvantage in gaining access to the ovules of the hermaphrodites in competition with the hermaphrodites' own pollen. By contrast, females in a gynodioecious species do not have this problem because hermaphrodites produce more than enough pollen to fertilize all available ovules. Gynodioecy may therefore evolve more readily, and this may be one reason why androdioecy is much rarer in nature than gynodioecy[22–24].

From gynodioecy one further evolutionary step can be taken to male heterogamety. It is assumed that females of gynodioecious species are homozygous recessives — for they will have lost male function through mutation, and most mutants are recessive. This makes it possible for full dioecy to evolve, though it can only be achieved by way of a dominant mutation that produces female-sterile (that is, male) plants, replacing the hermaphrodites[21]. Mutations at loci that are genetically closely linked to the male-sterility locus will be favoured over those that are not because they will be less likely to allow male-sterile and female-sterile plants to segregate in the population. As a dominant mutation is required to produce males, it is male heterogamety that will evolve from gynodioecy; and as gynodioecy is more common than androdioecy, the higher frequency of male heterogamety is thus explained.

The processes that lead to transitions between different systems of sex determination have received erratic attention from evolutionary biologists in general and population geneticists in particular. Bull's book[1] provides a general analytical framework for studying these processes, a comprehensive review of a relevant but scattered literature and a focus on unanswered questions. It also makes an excellent complement to Charnov's recent book on sex allocation theory[25], which considers how individuals should partition resources into male and female function[26]. □

Ions caught in their tracks

THE cloud chamber, once described by Lord Rutherford as "the most original and wonderful instrument in scientific history", dominated nuclear physics for half a century. It was invented almost inadvertently by C.T.R. Wilson when he sought to duplicate in the laboratory the optical effects produced by the interplay of clouds and sunlight encountered on a climbing holiday in Scotland in 1894. To generate artificial mist, Wilson designed a chamber in which to expand moist air and found that mist formed above a critical value of the expansion. Experimenting with the X rays discovered by W.C. Röntgen in 1895, he discovered that below that value the passage of the rays was rendered visible by a condensation track formed from the supersaturated air. He had in effect constructed a particle detector.

The design was progressively modified and improved, and in 1911 Wilson was ready to record the transitory tracks photographically. With a small cylindrical chamber activated by a piston from below, it was possible to record clearly the droplets condensing along the tracks not only of X rays but also of α, β and γ rays. Wilson concluded that the tracks "of ionising rays of any kind through a moist gas may be made visible by condensing water upon the ions set free".

The accompanying photograph, taken at the Cavendish Laboratory in 1911 by the light of a mercury spark, was the first published in Wilson's historic paper 'On a method of making visible the paths of ionising particles through a gas' (*Proceedings of the Royal Society* **A85**, 285; 1911). A potential difference of 8 volts was applied between roof and floor of the chamber. The camera was fitted with a Beck 'isostigmar' lens at f/5.8 and loaded with an Ilford Monarch plate. The shower of tracks traces the passage of α particles — helium nuclei — from a dot of radium on the tongue of a spinthariscope (left). "The very beautiful sight of the clouds condensed along the tracks of the α particles was seen for the first time", recalled Wilson in his Nobel lecture of 1927. The photograph is reproduced by courtesy of the Science Museum, where the 1912 version of the Wilson cloud chamber is preserved. **Jon Darius**

Chemistry

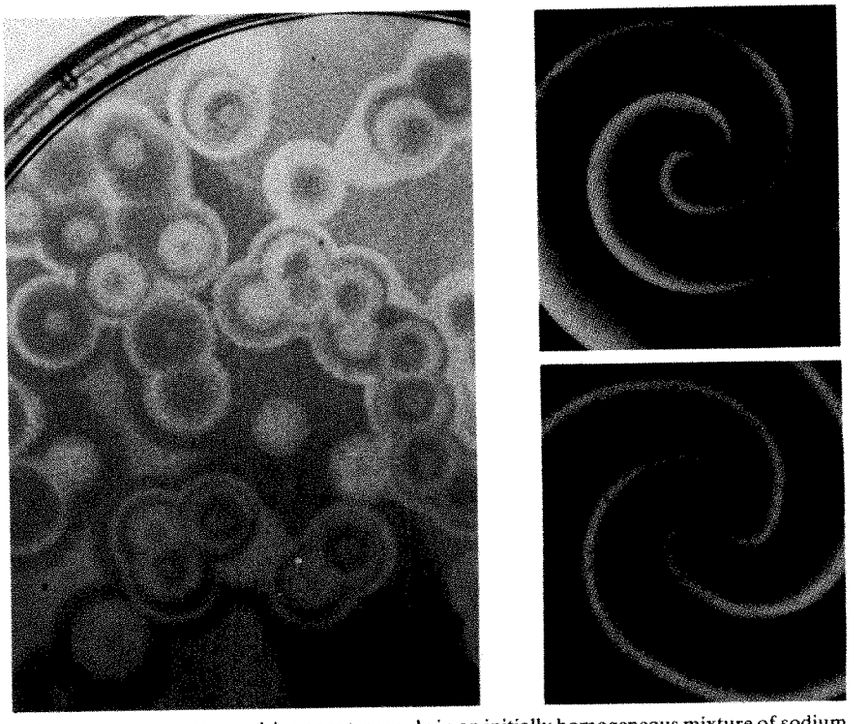
Chemically generated spatial structures

from Irving R. Epstein

IT might seem self-evident that a pattern formed by inhomogeneities in a liquid will eventually blur and disappear through the action of diffusion and that a liquid that is homogeneous will remain so. But recent work in nonlinear chemical dynamics is providing a set of extraordinary examples that do not conform to the intuitively attractive notion that spatial structures tend to decay rather than grow. These phenomena and the models proposed to describe them are beginning to have an impact not only in chemistry but in biology and geology as well, though some of the models are still highly controversial.

Probably the most venerable spatial structures seen in solutions are the Liesegang rings, known since the turn of the century[1]. Two solutions containing a pair of ions, such as silver and dichromate, which form a sparingly soluble compound, are placed at opposite ends of a tube containing a gel. As the ions diffuse towards one another, precipitate appears not, as one might expect, uniformly, but in a series of sharp nearly periodically spaced rings. Theories recently developed by Ross[2], Ortoleva[3] and co-workers challenge a 60-year old view[4] that the phenomenon results from the build-up and release of supersaturation. These new theories successfully explain Liesegang's as well as newer and more puzzling experiments by invoking the competitive autocatalytic growth of different sizes of colloid particles coupled to diffusion of the reactants. Ortoleva[5], by applying similar ideas, but on much larger scales of time and length, is able to explain the development of textural patterns in initially unbanded metamorphic rock — although the approach has met with some resistance from geologists.

Particularly exciting visually is the spontaneous development of trigger wave or bull's eye patterns (see the figure) in an initially homogeneous disc of reactant liquid. Winfree[6] has developed recipes and techniques for producing spirals and scroll waves as well as the simpler patterns, and Krinsky[7] has been able to generate multi-armed vortices (see the figure). A recent paper in *Nature* describes how to add a third dimension to these structures[8], while in this issue (p.717), Avnir and Kagan describe structures generated at membrane surfaces. Early studies of these phenomena were limited to a single chemical system, the Belousov-Zhabotinsky (BZ) oscillator, but De Kepper *et al.*[9] have shown that the same patterns may be observed in systems with quite different chemistry. The resemblance between these chemical structures and those seen in the aggregating slime mold *Dictyostelium discoideum*[10] are striking.



These patterns may be understood in a general sense as the result of a dynamic instability arising from the coupling of a chemically excitable system with diffusive transport and a recent computer simulation based on a two-parameter model[11] yields patterns remarkably like those found in the BZ reaction. However, a convincing calculation that predicts the wave pattern from a plausible chemical mechanism for a system as complicated as the BZ reaction has yet to appear. A first step in that direction has been taken by Showalter and colleagues[12], who treat a simpler phenomenon, the propagation of a single concentration wave in the arsenite-iodate reaction, by adding one-dimensional diffusion terms to a plausible model for the chemistry. Both the shape and the velocity of the wave are accurately predicted.

One rather controversial class of spatial phenomena is generated photochemically when initially homogeneous solutions are illuminated. Two recent papers[13,14] have refuted earlier claims of periodic temporal oscillation in the light emitted by certain photochemical systems subject to constant illumination. Instead, the observed behaviour is shown to result from spatial oscillations generated by convective motion of the fluid in response to temperature gradients set up by the illumination. (A related controversy involves the report published in *Nature* a few months ago[15] that previously published photochemically generated spatial structures[13,16], too, result from convection rather than photochemistry.)

Although the study of spatial pattern formation in chemical systems is still in its infancy, it is progressing rapidly. Answers to the questions raised by some of these beautiful and often counterintuitive phenomena promise important insights not only into chemical dynamics but into such biologically significant problems as morphogenesis as well. □

Calcium-activated potassium channels and their role in secretion

Ole H. Petersen & Yoshio Maruyama

MRC Secretory Control Research Group, The Physiological Laboratory, University of Liverpool, PO Box 147, Brownlow Hill, Liverpool L69 3BX, UK

Single-channel recording by the patch-clamp technique has now characterized three kinds of membrane potassium channels activated by intracellular calcium ions in animal cells. These play a crucial part in the regulation of membrane potential and of secretion.

THE concentration of potassium ions (K^+) in cells relative to extracellular space is normally maintained either directly by the ATP-dependent sodium-potassium (Na^+-K^+) pump in the plasma membrane or, indirectly, by co-transport processes ultimately driven by the same mechanism[1-3]. The exit of K^+ from cells, on the other hand, is mediated by trans-membrane K^+ channels of which there are several kinds[4]. The K^+ channels whose activity is regulated by intracellular calcium ion (Ca^{2+}) concentration[5-7] are of particular interest because they suggest explanations of several well-known phenomena in which the export of K^+ from cells appears to be linked with changes of cell metabolism and membrane potential. These include the adrenaline-induced increase in plasma K^+ concentration (due to K^+ exit from liver cells)[8,9], salivary gland K^+ transients (due to K^+ exit from acinar cells)[10,11] and the 'Gardos effect' in erythrocytes (K^+ release from red cells)[12,13]. In the nervous system these channels play a major role in regulating electrical activity[14].

The advent of the patch-clamp technique for studying the behaviour of single trans-membrane channels[15-18] has made possible the recognition of several categories of K^+ channels in the membranes of animal cells. In what follows, we shall be concerned only with the K^+ channels activated by Ca^{2+}, of which there appear to be three distinct types—two which are sensitive to membrane voltage but which differ in K^+ conductance, and which are known as the 'large' and 'small' voltage-activated channels, and a third which is insensitive to membrane voltage, unselective among cations but which nevertheless is activated by Ca^{2+} ions. The presence of K^+ channels activated by Ca^{2+} has already been demonstrated in a variety of tissues from several species by means of single-channel recording[5-7,19-29]. Individual cells may contain more than one type of Ca^{2+}-activated K^+ channel[19,20].

The large K^+ channel

The existence of K^+-channels which are sensitive to the internal free Ca^{2+} concentration ($[Ca^{2+}]_i$) within the cell has been demonstrated only in the past few years by means of the patch-clamp technique (Table 1). That some of these channels have very high conductance was first demonstrated by Marty[6] in the membranes of cultured chromaffin cells. Conductances as great as 200 pS or more have been found in various cell membranes, and channels of this type are activated by membrane depolarization. Marty noted two effects of Ca^{2+} at the inner surface of the membrane—increasing probability that high-conductance channels will open on membrane depolarization and a modest decrease of conductance in open channels. While the first effect has been amply confirmed[7,20-23], the reported decrease of channel conductance with increasing $[Ca^{2+}]_i$ has not always been found[20,21,23].

The sensitivity of high-conductance K^+ channels to $[Ca^{2+}]_i$ seems to vary considerably from one preparation to another. Marty's original observations with cultured chromaffin cell membranes suggest that depolarization provokes full channel opening at a Ca^{2+} concentration of 10^{-8} M. At the same time, however, depolarization of inside-out patches of membrane from mammalian salivary glands evokes marked activation of these channels when the inner surfaces are exposed to nominally Ca^{2+}-free solutions containing 1 mM EGTA (ref. 20). By contrast, in cultured rat muscle cells, depolarization from −50 to +50 mV has been shown not to evoke channel opening at 10^{-8} M Ca^{2+}, to have virtually no effect at 10^{-7} M but to require internal concentrations of 10^{-6} M for channel activation[21]. While it seems that the high-conductance channels of the rat muscle preparation are Ca^{2+}-dependent (see ref. 21), in general it may be more appropriate to use the term 'Ca^{2+}-activated', since depolarization can open the channels in the absence of Ca^{2+} in many preparations[20].

In secretory cells such as the chromaffin and the salivary and pancreatic acinar cells, it is clear that the K^+ channel is strictly under the dual control of membrane potential and $[Ca^{2+}]_i$[6,20,23]. Under physiological conditions, an increase in $[Ca^{2+}]_i$ will increase the open state probability (switch on the channel), which will increase the membrane potential and so, in turn, reduce the probability of channel opening. Thus, K^+ exit is kept in good control. The Ca^{2+} sensitivity appears appropriate for physiological regulation since a change in $[Ca^{2+}]_i$ from 10^{-8} to 10^{-7} M causes a marked increase in open state probability and an increase to 10^{-6} M causes near maximal opening of the K^+ conductance pathway[23].

The conductance of the K^+ channel is very high. In symmetrical high-K^+ solutions, values of 180 to 250 pS have been obtained[6,20,23] (Table 1). The variations of conductance between different tissues are, however, puzzling. In our laboratory we generally find that the K^+ channels in pig pancreatic acinar cells have a conductance of about 200 pS whereas in the salivary glands of mice and rats, the channels have a conductance of about 250 pS. The possibility of sub-states of the channel has been raised by observations of smaller channels of varying conductances when membrane patches are artificially exposed to symmetrical high K^+ solutions[20,23], but detailed investigations of these smaller current steps have not been undertaken.

In spite of the high unit conductance, the K^+ channel is very selective. The channel discriminates between the closely related alkali metal ions K^+ and Rb^+. With extracellular Rb^+ and intracellular K^+, K^+ current can easily be made to flow from the inside to the outside, but no inward Rb^+ current can be evoked. With the Rb^+/K^+ gradients reversed, inward K^+ current, but not outward Rb^+ current, can be observed (Y.M., D. V. Gallacher and O.H.P., unpublished data). It is important to be aware of this rather extreme selectivity as ^{86}Rb is frequently used as a tracer in flux experiments to assess K^+ permeability since it has a much longer half-life than ^{42}K (ref. 2).

The K^+ conductance of the plasma membrane depends not only on the single-channel conductance and the probability of

Frog red cells	18, 50	K^+ channel	No	?	26

channels being open at any time, but also on the channel density. The number of channels in a cell can be estimated by a combination of patch-clamp single-channel and whole-cell current recording if the K^+ channel is the only channel of quantitative importance for the conductance of the plasma membrane in the whole cell. This condition seems fulfilled in the pig pancreatic acinar cells. In the resting condition, where $[Ca^{2+}]_i$ lies between 10^{-8} and 10^{-7} M there are about 50 large K^+ channels per acinar cell[23].

The small K^+ channel

Very few patch-clamp investigations of this channel, which may or may not be related to the possible substates of the large K^+ channel mentioned above, have been carried out and relatively few details are therefore known. Lux *et al.*[5] described a 19 pS Ca^{2+}-activated K^+ channel in *Helix pomatia* neurone which is switched on much more slowly than the large 200 pS channel, described above, following depolarization. A K^+ channel with a similar conductance (18 pS) is found in human red cells[24,25] but only after their treatment with iodoacetic acid and adenosine (Gardos treatment[12]). It has recently been shown that the small K^+ channel as well as a somewhat larger K^+ channel (50 pS) in frog red cells can be activated by internal Ca^{2+} (refs 25, 26).

Non-selective cation channels

Not all Ca^{2+}-activated channels are selective. A Ca^{2+}-dependent non-discriminatory cation channel with a conductance of about 30 pS at room temperature (the conductance of this channel is very temperature sensitive) was first described by Colquhoun *et al.*[27]. In marked contrast with the large K^+ channel, the non-discriminatory channel is virtually voltage-insensitive. It is a truly Ca^{2+}-dependent channel in the sense that opening and closure of the channel cannot be observed in the absence of Ca^{2+} on the inside of the membrane. Such channels have subsequently been found in mouse neuroblastoma cells[19], mouse and rat pancreatic acinar cells[28,29] and rat thyroid follicular cells (D. Moor and Y.M., unpublished observation). The channel is virtually impermeable to Cl^- (refs 19, 27, 28) and is almost equally permeable to all the alkali metal ions[19]. Permeability for Ca^{2+} has not been directly demonstrated[19,30], is certainly low, but may not be entirely insignificant[31]. The precise relationship between the open state probability of the channels and $[Ca^{2+}]_i$ is not yet known. We have found that channel opening can be observed at $[Ca^{2+}]_i = 10^{-7}$ M immediately after excision of a pancreatic acinar membrane patch into the inside-out conformation but that after 10–20 s, higher (eventually micromolar) Ca^{2+} concentrations are required to evoke channel opening (Y.M. and O.H.P., unpublished data). The fact that the responsiveness of channels to $[Ca^{2+}]_i$ decreases with the passage of time suggests that the commonly reported observations[19,27–29] that the channels are insensitive to Ca^{2+} may not describe the behaviour of these unselective channels in intact cells. It is relevant that the pancreatic secretagogue cholecystokinin (CCK) has been shown indirectly to activate the non-discriminatory channel in intact pancreatic acinar cells via internal Ca^{2+} (ref. 29).

Role in secretion

From a biophysical point of view, two types of secretory cells can be distinguished: those with and those without the ability to conduct electrical action potentials. In general, epithelial cells seem not to fire action potentials whereas most endocrine cells do. (There are, however, exceptions to this rule[32].)

Endocrine cells: In the endocrine cells the K^+ channel acts as a link between $[Ca^{2+}]_i$ and the membrane potential. In typical endocrine cells, such as the chromaffin and the pancreatic β-cells as well as in nerve endings, Ca^{2+} needed in excitation-secretion coupling enters the cells through specific voltage-gated Ca^{2+} channels[33–37] which are opened by membrane depolarization and closed by hyperpolarization. Therefore, as the entry of Ca^{2+} produces an increase in $[Ca^{2+}]_i$, so the K^+ selective channels will be activated leading to membrane hyperpolarization and impedance of further Ca^{2+} influx. A particularly beautiful example of the interplay between Ca^{2+} influx, $[Ca^{2+}]_i$ and K^+ conductance resulting in an oscillating membrane potential pattern (depolarization—plateau with Ca action potentials—hyper-

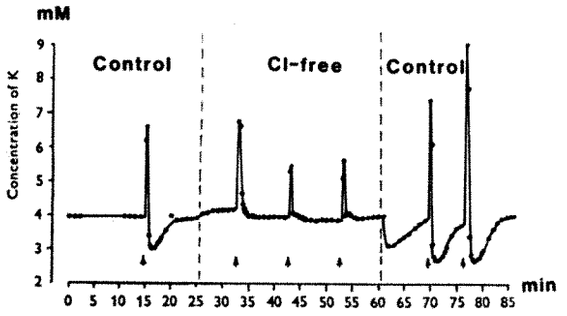

Fig. 1 Acetylcholine-evoked K^+ release and reuptake in perfused cat submandibular gland. The figure shows the concentrations of K^+ in the venous outflow from the gland in one typical experiment. The perfusion fluid flowing into the gland was a physiological saline solution containing 4 mM K^+. Arrows denote injection of 10 μg ACh into the arterial inflow to the gland. In the control periods the major salt component of the oxygenated perfusion solution was 140 mM NaCl whereas during the period labelled Cl-free it was 140 mM $NaNO_3$. Osmolarity, *p*H, K^+ and Ca^{2+} concentrations were kept constant throughout. Note that although the first ACh stimulation in the Cl^--free period evokes a normal K^+ release the K^+ reuptake is virtually abolished. Cl^- readmission evokes immediate K^+ reuptake. The fluid secretion responses to ACh during the Cl^--free perfusion were about 30% of the values obtained in the second control period (from ref. 47).

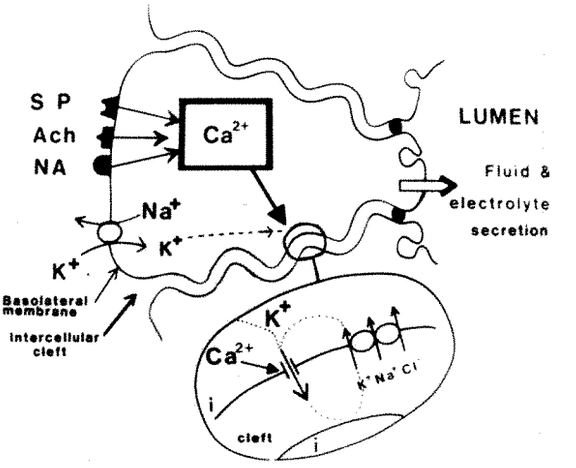

Fig. 2 Simplified scheme to account for control of electrolyte transport in baso-lateral plasma membrane of fluid secreting epithelia. The figure specifically represents part of a mammalian salivary gland acinus and its major secretagogues, substance P, acetylcholine and noradrenaline but with other secretagogues and/or various additions, the model could represent a wide range of secretory epithelia. In the proposed scheme, secretagogues first increase $[Ca^{2+}]_i$ (as suggested by a variety of evidence[32,34,35,72–74] including a recent direct demonstration in mouse acinar cells [75]). The increased $[Ca^{2+}]_i$ would open Ca^{2+}-activated K^+ channels in the baso-lateral membranes of the cell (such channels are well known[20,23], there is some evidence of their localization in the lateral plasma membranes[65] and a decrease in intracellular and increase in extracellular K^+ activity following stimulation have been demonstrated[45,46]). K^+ released through the channels into the narrow intercellular clefts would be taken up again, primarily through a K^+-Na^+-Cl^- co-transport system. The rate of transport in the cycle of K^+ release and reuptake would be regulated at the K^+ channel by internal Ca^{2+} and would be directly linked to the rate of NaCl uptake by the cotransport system. In the salivary glands it is likely that part of the K^+ release occurs via the Ca^{2+}-activated non-selective cation channel[20] explaining why the intracellular Na^+ concentration rises during stimulation[47,48] and part of the K^+ uptake could occur via the Na^+-K^+ pump (but intracellular Na^+ activity measurements have not been carried out). The operation of the Na^+-K^+-Cl^- co-transport system is of course dependent on the Na^+ gradient and therefore ultimately on the operation of the Na^+-K^+ pump. (Note that there is no evidence in regard to specific localizations of Na^+-K^+ pump and co-transport system to basal and lateral membranes, respectively and the two transport proteins probably co-exist both in the lateral and basal plasma membranes.) The Na^+-K^+-Cl^- co-transport is probably electroneutral as the most likely stoichiometry is 1 Na^+, 1 K^+ and 2 Cl^- (ref. 58).

polarization—gradual slow depolarization—depolarization . . .) was demonstrated several years ago by Gorman and Thomas in *Aplysia* neurones[38]. Interestingly, as previously pointed out[32], this pattern resembles very much that seen in mammalian pancreatic β-cells[39]. Ca^{2+}-activated K^+ channels[40] can indeed be regarded as the crucial regulatory link between $[Ca^{2+}]_i$, and therefore insulin secretion, and Ca^{2+} influx[32,41,42]. The insulin secretagogue glucose, according to one hypothesis, acts by decreasing the Ca^{2+} sensitivity of the K^+ channels, prolonging the plateau phase with the Ca^{2+} action potentials and thereby enhancing $[Ca^{2+}]_i$ (refs 32, 41, 42).

Exocrine cells: The role of Ca^{2+}-activated K^+ channels in the epithelial cells from which action (spike) potentials are absent must clearly be a very different one. The fluid-secreting epithelia of several tissues (salivary glands, sweat glands, lacrimal glands, the exocrine pancreas, the gastric mucosa and the tracheal epithelium) are under strict nervous and/or hormonal control. In many of these tissues it has been clearly shown that nervous or hormonal activation of secretion is associated with release of cellular K^+ (refs 32, 43). The salivary glands, which have been investigated in considerable detail, will be treated here as a model for other fluid-secreting epithelia.

Salivary gland acini secrete an isotonic plasma-like fluid at a low rate (if at all) in the resting condition but at an extraordinarily high rate during nerve stimulation[43]. Secretion is Ca^{2+} dependent[44]. Nerve stimulation or direct stimulation with acetylcholine, noradrenaline or substance P evokes loss of cellular K^+ (refs 32, 43). Both a marked decrease in intracellular K^+ and a marked increase in extracellular K^+ have been measured[45,46]. The stimulant-evoked K^+ loss, which is due to electrodiffusion[47,48], can be evoked in the absence of neurotransmitter stimulation by the Ca^{2+} ionophore A23187 (ref. 49). The direct demonstration of the large Ca^{2+}-activated K^+ channel in the baso-lateral plasma membranes of several mammalian salivary glands explains the stimulant-evoked K^+ loss and the Ca^{2+}-involvement[20]. Following release of K^+ from stimulated salivary glands, there is reuptake of K^+. This has generally been assumed to be due to operation of the ouabain-sensitive Na^+-K^+ pump and certainly K^+ reuptake (but not stimulant-evoked K^+ release) can be blocked in the presence of ouabain[47]. However, as seen in Fig. 1, K^+ reuptake is also acutely and reversibly abolished when the Cl^- component of the perfusion fluid is replaced by NO_3^- (ref. 47) (similar results were obtained using sulphate replacement[50]). Stimulant-evoked secretion is markedly reduced under these conditions as first shown by Lundberg[51]. The K^+ reuptake and secretion are also acutely sensitive to reductions in extracellular Na^+ concentration[47]. These findings could be explained by postulating linked K^+, Na^+ and Cl^- inward movement through a carrier system (Fig. 2) of the type now characterized in red cells[52–56], kidney cells[57–58] and the intestine[59], but not known to exist at the time of the original observations[47,51]. The involvement of a K^+-Na^+-Cl-co-transport system in secretion from the salivary gland is also supported by Lundberg's observation that replacement of Cl^- in the perfusion fluid by NO_3^-, I^- or SCN^- but not by Br^-, reduced the secretory responses by 85–90% (ref. 60). This resembles the situation in erythrocytes where only Br^- can replace Cl^- in the operation of the co-transport system although all the other anions can be equilibrated across the membrane by the anion (Cl^--HCO_3) exchanger[52,55].

The novel feature of the model proposed in Fig. 2 is that cycling of K^+ through channel and co-transport system allows NaCl uptake through the basolateral membrane of the cell and that the rate of NaCl uptake is directly linked to the rate of transport in the cycle of K^+ release and uptake. The point of

regulation has been clearly identified at the molecular level as the Ca^{2+}-activated K^+ channel[20]. The ability of ouabain slowly to block the K^+ reuptake[47] is of course entirely consistent with the hypothesis proposed, since uptake through the co-transport system will be dependent on the presence of the Na^+ gradient. The model shown in Fig. 2 does not deal with the processes in the luminal membrane, but our hypothesis is not incompatible with the experimental results obtained on *Calliphora* salivary glands and many other tissues suggesting the presence of a luminal Ca^{2+}-activated Cl^- conductance controlling salt exit from the epithelium[61–63]. Indeed it would seem desirable, perhaps even necessary, as suggested by Burgen[64], to have control of transport at both baso-lateral and luminal plasma membranes.

It may be questioned whether K^+ release through Ca^{2+}-activated K^+ channels is large enough to cause a marked change in the transmembrane K^+ gradient but in several salivary glands the changes have been shown directly to be very substantial (Fig. 1) (see also refs 11, 45, 46). The measurements of extracellular K^+ activity in cat and dog submandibular glands show maximal increases after nerve stimulation of 15–18 mM (ref. 45). The changes in K^+ activity along the lateral plasma membrane (narrow extracellular clefts between the cells[32]) are, however, likely to be even larger. A recent voltage clamp study on mouse pancreatic acini indicates that the ion channels controlled by secretagogues mainly reside in the lateral membranes bordering on the narrow extracellular spaces[65]. If this is generally true then nearly all the K^+ will be released directly into the intercellular spaces and the K^+ activity obtained at this site will clearly be higher than in the interstitial fluid at large.

The initial stimulant-evoked change in the transmembrane K^+ gradient is likely to provide a major stimulus for salt uptake via the co-transport system (explaining the very high initial secretory rates[43]), but there is evidence that it is only short-lived[45]. However, even in the steady state situation of sustained secretion, it is essential to maintain the open state of the K^+ channels as continued K^+ exit must balance the K^+ uptake via the co-transport processes since the primary acinar secretion has a low (plasma-like) K^+ concentration[43].

Future perspectives

Although detailed investigations of the properties of the Ca^{2+}-activated K^+ channels have been carried out on several different cell types, little is yet known of the mechanisms involved in modulation of the channels by hormones and neurotransmitters. Recent evidence from our laboratory suggests that the pancreatic secretagogue CCK, acting via an increase in $[Ca^{2+}]_i$, not only increases the open state probability of the large K^+ channel in pig pancreatic acinar cells but also rapidly (and reversibly) increases the number of K^+ channels per cell, (2–3-fold increase with 2×10^{-10} M CCK). The mechanism is unknown but the observations are reminiscent of those in which ADH and aldosterone have been shown rapidly to increase the density of amiloride-sensitive Na^+ channels in the toad urinary bladder[66,67]. The role of protein phosphorylation in controlling K^+ conductance is also likely to demand further attention. Voltage-clamp studies of the Ca^{2+}-activated K^+ conductance in internally perfused snail neurones show an enhancement of the outward K^+ current after addition of the catalytic sub-unit of cyclic AMP-dependent protein kinase to the internal perfusing medium[68], but single-channel current studies are not yet available. The role of the Ca^{2+}-activated K^+ channels in secretion, in particular in epithelial cells, also needs to be further clarified. The availability of specific blockers for the different channels would be an enormous help, but satisfactory compounds have not been found. The possible physiological regulatory role of internal Na^+ blockade of the large Ca^{2+}-activated K^+ channel[69] should be investigated. The finding that the large Ca^{2+}-activated K^+ channel has a very low conductance for Rb^+ should allow interesting experiments on the role of this particular channel to be carried out in various tissues.

Revised Sm–Nd systematics of Kambalda greenstones, Western Australia

J. C. Claoué-Long*, M. F. Thirlwall† & R. W. Nesbitt*

* Department of Geology, Southampton University, Southampton SO9 5NH, UK
† Department of Earth Sciences, Leeds University, Leeds LS2 9JT, UK

Sm–Nd isotope systematics in mafic–ultramafic lavas from the Norseman–Wiluna greenstone belt, Western Australia, have been reinvestigated. A previous age based on mixing lavas and granites is not confirmed: instead, a Sm–Nd age of 3,262 ± 44 Myr is indicated for the lavas, 400 Myr older than intruding granites, and predating gneisses that have been proposed as basement rocks.

OPPOSING models for the development of the early crust preserved in the Yilgarn Archaean craton suggest either that gneiss terrains represent basement on which later greenstones were deposited[1,2], or that greenstones formed the early crust (at least in part) and granitoids were produced by partial melting of greenstones infolded to deep crustal levels[3]. Field relationships and geochronology are among the keys to settling this debate, but information is scarce and somewhat equivocal. Sm–Nd studies may prove useful for determining ages in the greenstone belts, but the method is hampered by a lack of preservation of original igneous minerals and the normally small range of whole-rock Sm/Nd ratios found in co-genetic suites of lavas. A previous attempt to apply Nd isotopes to the Kambalda area combined lavas with felsic intrusive rocks to generate a wide range of parent/daughter ratios, and produced an age for these samples of 2,790 ± 30 Myr (ref. 4). This approach is open to the danger that the samples are probably neither co-genetic nor of the same age. In acknowledging this, the previous paper notes that data for Kambalda lavas alone yield a poorly-constrained older date. Against this background, the present study discusses new Nd data for basic–ultrabasic lavas in the Kambalda region.

Regional geology

Correlations within the 800 km long Norseman–Wiluna greenstone belt are complicated by extensive strike-faulting and poor exposure, but in the Kambalda area there is sufficient continuity to permit recognition of two sequences of volcanic and sedimentary rocks, referred to as the Kambalda (lower) and Bluebush (upper) sequences[5,6] (Fig. 1). Although both horizons exhibit similar ranges of lithologies, nickel sulphides are preferentially concentrated in the Kambalda sequence. The area has been affected by at least four deformational events, as well as metamorphism (up to low amphibolite facies) and intrusion of Archaean granitoids, felsic–intermediate porphyries, minor mafic dykes and sills, and a Proterozoic dolerite dyke suite[6]. Thus all rocks are now metamorphic, but good preservation of igneous textures and chemistry merits consideration of the metalavas as igneous rocks.

Mafic–ultramafic lavas in the Kambalda sequence consist of >2,000 m of pillowed, or massive, fine-grained foot-wall basalts with 6–9% MgO, overlain by 0–1,000 m of ultrabasic lavas (olivine–spinifex textured komatiites, liquid composition 22–31% MgO), and subsequently by >600 m of hanging-wall basalts with <15% MgO (ref. 6). These are commonly pillowed and variolitic, but can be massive or occasionally bear pyroxene-spinifex. At the base of the ultrabasic formation occur one or more very thick flows, hosts to Ni–Cu sulphides, which are layered and contain differentiation zones of basaltic pyroxene-spinifex with <15% MgO. Lavas at the Kambalda Dome are intruded by a sodic granite and a series of felsic porphyries.

The Bluebush sequence is less well understood, but also consists of an ultrabasic formation sandwiched between basaltic foot–wall and hanging-wall formations. Attention here is confined to the ultrabasic formation, which is best known from good surface exposures at Ultramafic Hill and One Boob Hill, and consists of well-preserved interlayered flows of olivine-spinifex textured komatiite and pyroxene-spinifex textured basalt[6,7].

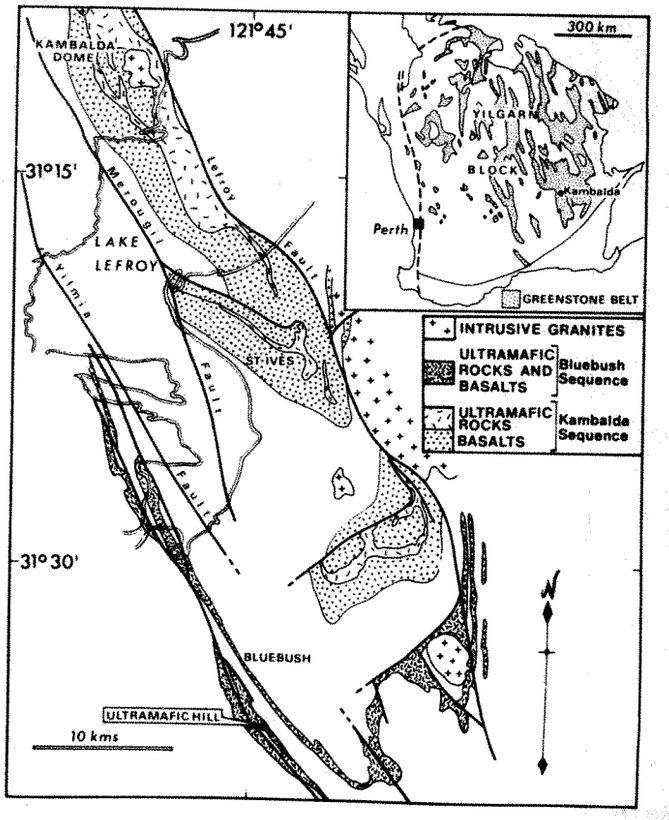

Fig. 1 Distribution of mafic and ultramafic lavas in the Kambalda–Bluebush area of the Norseman–Wiluna belt (adapted from ref. 6). Inset shows location of Kambalda in the Yilgarn block.

HWB, hanging-wall basalt; FWB, foot-wall basalt. Errors quoted are 2 standard errors on the mean. $^{147}Sm/^{144}Nd$ and $^{143}Nd/^{144}Nd$ determined on aliquots of the same sample solution. Total Nd blank is 0.2 ng and is therefore negligible for this study. $^{143}Nd/^{144}Nd$ normalized to $^{146}Nd/^{144}Nd = 0.7219$, the value determined for BCR1 = 0.512657 ± 12. A revised calibration of the Leeds rare-earth spike using standard solutions prepared from metal ingots gives Sm/Nd = 0.3249 for the California Institute of Technology Sm/Nd Standard[25], and reproducibility of $^{147}Sm/^{144}Nd$ is 0.1% 2σ.

Methods and results

Much of the ensuing discussion revolves around the choice of samples. Original igneous minerals are not preserved in the Kambalda and Bluebush lavas, and whole-rocks have been used. In contrast to the previous study, which combined mafic–ultramafic volcanics with felsic plutonic rocks to produce a wide range of Sm/Nd ratios[4], the approach adopted here is to use only mafic–ultramafic lavas. Samples from the Kambalda sequence are all from deep diamond-drill holes through the Kambalda Dome. Care was taken to choose rocks with good preservation of igneous textures, and to avoid visible forms of alteration (apart from the pervasive amphibolite facies metamorphism) such as biotite-rich zones, variolitic forms of basalt, and carbonation. Only surface samples are available from the Bluebush sequence: those used are all from the 400 m Ultramafic Hill section, where field relationships are best exposed, and were chosen for quality of textural preservation from portions of very large specimens free from obvious surficial weathering.

Analytical methods used for rare earth elements (REE) and Nd isotopes are described elsewhere[8,9]. Results for Kambalda and Bluebush are listed in Tables 1 and 2, and the data are plotted on an isochron diagram in Fig. 2*a*. A very wide range of Sm/Nd ratios has been found in the mafic–ultramafic lavas alone, and, with one sample excluded, the new data for Kam-

Table 2 Isochron results

Data set	Age (Myr)	$(^{143}Nd/^{144}Nd)^{i}$	ε^{i}_{Nd}	MSWD	n

Regressions by the method of York[26]. All errors are 2σ, and are multiplied by √MSWD when MSWD > 1. ε^{i}_{Nd} is a measure of the deviation in $^{143}Nd/^{144}Nd$ of a suite of samples from a reference composition CHUR (chondritic uniform reservoir)[27], and is calculated by comparing the present day composition, $(^{143}Nd/^{144}Nd)^{0}_{Sa}$, of a hypothetical sample having $(^{147}Sm/^{144}Nd)^{0}_{Sa} = (^{147}Sm/^{144}Nd)^{0}_{CHUR}$, with the present day composition, $(^{143}Nd/^{144}Nd)^{0}_{CHUR}$, of CHUR according to the definition of ref. 21:

$$\varepsilon^{i}_{Nd} = \left[\frac{(^{143}Nd/^{144}Nd)^{0}_{Sa}}{(^{143}Nd/^{144}Nd)^{0}_{CHUR}} - 1\right] \times 10^{4}.$$

Present day reference values for CHUR[28] are:

$$(^{143}Nd/^{144}Nd)^{0}_{CHUR} = 0.51264 \quad \text{and} \quad (^{147}Sm/^{144}Nd)^{0}_{CHUR} = 0.1967.$$

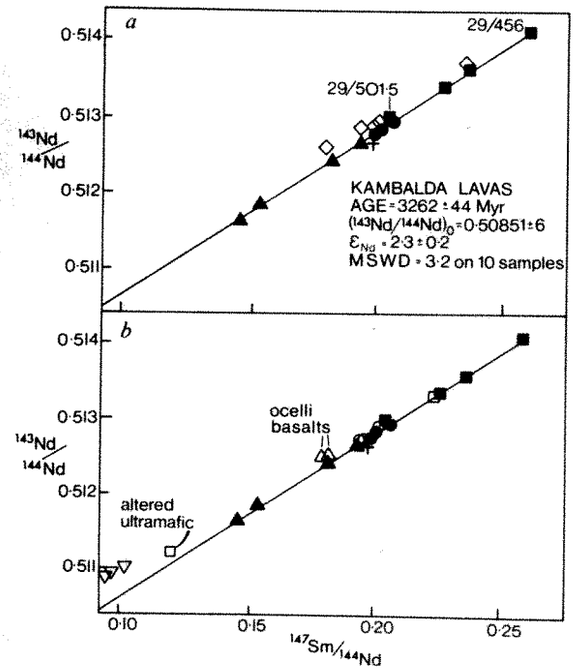

Fig. 2 *a*, Sm–Nd evolution diagram for Kambalda and Bluebush data in Table 1. Isochron plotted is for Kambalda only (omitting sample 29/501.5, see discussion). *b*, Data and isochron for Kambalda plotted as in *a* (solid symbols) compared with data from ref. 4 (open symbols). Previous data for ocelli-basalts do not coincide with purely mafic lavas in the hanging-wall formation (new data), and the tightly-constrained lavas isochron does not extrapolate to points representing intrusive granites. Kambalda: ●, footwall basalts; ■, komatiites; ▲, hanging-wall basalts; ▽, granites. ◇, Bluebush lavas. + Represents the present-day chondritic value.

balda yield a tightly constrained isochron (MSWD = 3.2) of age 3,262 ± 44 Myr with an initial $^{143}Nd/^{144}Nd$ of 0.50851 ± 6 and $\varepsilon^{i}_{Nd} = 2.3 \pm 0.2$. Data for Bluebush do not form an isochron, but plot separately from the Kambalda line and clearly have a much higher ε^{i}_{Nd} value in the region of 5–6.

The sample excluded (29/501.5) from the otherwise coherent new data set for Kambalda is from the basaltic differentiation zone of a layered komatiite flow whose flowtop is also analysed (sample 29/456, see Fig. 2*a*). It is not possible to ascribe the severe divergence in Sm/Nd ratio (22%) between this sample and the flowtop composition to simple crystal fractionation within the flow, and it is unique in departing from the otherwise regular and predictable variation found in the rest of the data set. 29/501.5 lies close to a minor basic intrusion, and its unusual Sm–Nd composition suggests that a process of exchange of light-REE (LREE) with the younger intrusion may have occurred.

The new results for the Kambalda lavas are not colinear on the isochron diagram with re-normalized data from a previous study[4] (Fig. 2*b*). Unfortunately there are no sample descriptions in the previous paper, but the two basalts most divergent from the new data are referred to as ocelli-bearing. This type has been avoided in the present study in the belief that purely mafic varieties are more likely to preserve original igneous geochemistry. An anomalous ultramafic sample is also reported by the previous authors, who believe it unlikely to represent original igneous geochemistry (for reasons similar to those given above with respect to sample 29/501.5), and they report that it came from an alteration zone at the margin of a felsic porphyry.

A total of 18 samples of lavas were selected by this and the previous study as *a priori* candidates for analysis, and definition of an isochron. Of these, it is apparent that ocelli-basalts and an altered ultramafic rock from the previous paper, and a further ultramafic sample from this study, no longer possess original igneous Sm–Nd compositions, and they are excluded from further discussion. Rejection of these samples does not invalidate the regression defined by the remaining lavas, but does make it less easy to justify. However, it is notable that the four other data points for lavas used in the previous study (one ultramafic, three foot-wall basalts) plot together with the new data. Combining these four data points with the new analyses yields a line within error of that based on the new results alone, and a comparable age (3,274 ± 57 Myr), initial $^{143}Nd/^{144}Nd$ (0.50851 ± 7), and ε^{i}_{Nd} (2.4 ± 0.2).

The poor coherence of data for the Bluebush lavas is most unlikely to reflect variation in ages of the flows that were sampled. The scatter could represent orginal variations in initial $^{143}Nd/^{144}Nd$, but it is not possible to rule out disturbance of the Sm–Nd isotopic system by weathering of the surface samples.

Whole-rock 'isochrons'

To obtain a wide spread of parent/daughter ratios, the previous Sm–Nd study of Kambalda enlisted a mixture of whole-rock samples ranging from komatiite to granite, on the assumption that such diverse samples may have the same age and essentially homogeneous initial $^{143}Nd/^{144}Nd$ (ref. 4). This assumption is the main weakness of whole-rock dating applied in the absence of mineral data. Justification for such studies can come from the internal consistency of results so obtained, and indeed the previous interpretation of the komatiite–granite correlation as a real age for Kambalda was based on the tightness of the regression through all the samples used. However, the slope of this regression was largely controlled by the samples of granite, and the large variation in Sm/Nd now found in the mafic–ultramafic lavas alone produces a tightly-constrained line that does not extrapolate through the granite data (Fig. 2*b*). This strongly suggests that the lavas and granites were derived from isotopically distinct sources, and that the age derived from mixing the plutonic and volcanic samples is spurious. However, it remains to be shown that the correlation within the lavas is not a mixing line between magmas from an isotopically heterogeneous mantle.

Reference to Fig. 3 shows that, regardless of Sm/Nd ratios, all lavas in the Kambalda sequence have essentially flat heavy-REEs (HREEs), whereas Bluebush lavas show HREE depletion. This difference corresponds to a worldwide division of komatiite types previously thought to reflect temporal changes in komatiite genesis[10]: early HREE-depleted komatiites (for example, in the Barberton belt) are thought to result from garnet control in the mantle, whereas younger lavas so far studied have chondritic ratios of HREE and do not show the influence of garnet separation. The temporal sequence of source regions is reversed with the Kambalda and Bluebush lavas, and their close spatial association alone is evidence that mantle heterogeneity existed below the Kambalda region during the Archaean.

The foot-wall, komatiite and hanging-wall formations at Kambalda each represent co-magmatic lava batches. Within each formation, variations in Sm/Nd ratio (34% for the hanging-wall basalts, 27% for the komatiites) may be ascribed to either the combined effects of differing degrees of partial melting of, and fractionation in, magmas from a homogeneous source, or the possibility that Sm/Nd in each lava directly reflects variations in Sm/Nd within the source area. Continuity of source composition between formations is not easy to justify because the variation in Sm/Nd ratio between lava batches is large (Fig. 3), and a very high degree of LREE fractionation is indicated if the same source is involved.

Taking the worst case, it is possible that the corrrelation on the isochron diagram is a mixing line between lavas derived from two, perhaps more, mantle sources possessing different Sm/Nd ratios. This leaves two main alternatives: (1) the lavas were erupted 3,200–3,300 Myr ago as the lavas correlation suggests. This requires that any Sm/Nd heterogeneity between the two (or more) mantle sources existed for a very short time before eruption of the three batches of magma. (2) The lavas

were erupted at 2,700–2,900 Myr as has previously been supposed. In this case the correlation in Fig. 2 represents mixing of data from a mantle that possessed long-lived heterogeneities in Sm/Nd.

These alternatives may be investigated by examining how data points for the individual lava batches fit the isochron. If lavas are co-genetic within each of the Kambalda formations, then individual true isochrons are defined by the limited numbers of points in each group. Errors on the ages yielded by these domains within the isochron are large, because of the limited spread of Sm/Nd ratios found in any one formation, but they are equal within error and constrain the age to older than 3,100 Myr (see Table 2). An additional constraint arises from the fact that the age deduced from the whole data set lies within the errors of the ages deduced from the individual formations. If mantle heterogeneity in Sm/Nd had existed for a significant time before eruption, then each source would have evolved $^{143}Nd/^{144}Nd$ separately to generate distinct initial ratios. As a consequence, isochrons through the domains would be parallel, but offset relative to one another by an amount proportional to the degree, and duration, of the heterogeneity. The regression

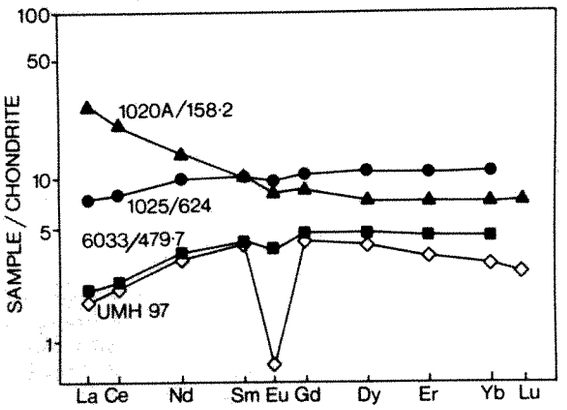

Fig. 3 Chondrite normalized REE abundances for selected Kambalda and Bluebush samples (symbols as for Fig. 2). Kambalda lavas have essentially flat HREE patterns, and show pronounced variation in LREE slopes. The Bluebush komatiite has identical LREE depletion to its Kambalda counterpart, but is depleted in HREE also. The large negative Eu anomaly may be due to alteration in the Bluebush surface sample.

through all the data would give an older age than isochrons through the individual magma batches. This 'tram line' effect is not observed in the Kambalda data, a point which is also illustrated by the homogeneous ε^{i}_{Nd} of the subsets.

Another explanation of Sm–Nd variations in the Kambalda samples is that the Sm/Nd ratio of each lava directly reflects Sm/Nd heterogeneities within the source region. This implies that essentially no fractionation of LREE occurred during partial melting and eruption and, therefore, the 3,262 ± 44 Myr age given by the lavas isochron would refer to the date of differentiation of sources within the mantle, not necessarily the date of eruption. If the lavas were subsequently erupted at 2,800 Myr, this model requires that the hanging-wall basalts were partially melted from a source which had been LREE-enriched for 400 Myr. Thus sample 1020A/158.2 would have to come from mantle source with $\varepsilon^{i}_{Nd} = -1.0$ at 2,790 Myr. However, available evidence suggests that the Archaean mantle was characterized by long-lived depletion of large-ion lithophile (LIL) elements[11–13] and it seems probable that if a LREE-enriched region existed in the mantle below Kambalda, it was created a short time before, or during, the partial melting event.

These arguments suggest that, while variations in Sm/Nd ratio almost certainly existed in the source of the Kambalda lavas, they were short-lived. Any heterogeneity of initial $^{143}Nd/^{144}Nd$ was therefore insignificant in terms of the error of the Nd age, and it is concluded that the data yield a true age for the lavas, which were erupted >3,200 Myr ago.

Archaean mantle

In the compositions of the Kambalda and Bluebush lavas there lies evidence for the existence of a wide variety of source regions. The revised Kambalda ε^{i}_{Nd} value of 2.3 ± 0.2 is 30% lower than that obtained from the komatiite–granite regression[4]. However, it confirms the depleted source for the greenstones found by the previous authors, is consistent with $\varepsilon_{Nd,t}$ values obtained for Archaean mafic–ultramafic volcanics of various ages in other cratons[11–13], and is further evidence for worldwide distribution of long-lived LIL-element depletion in at least part of the Archaean mantle. It is argued above that this already-depleted mantle may have undergone a separation, shortly before 3,200–3,300 Myr ago, into compositions ranging from LREE depleted to LREE enriched, and within a short time span these became sources for the three batches of magma erupted at Kambalda.

Another window into the mantle is provided by the stratigraphically-younger Bluebush sequence. Despite the scatter of data for these lavas, it is apparent that they derive from a very radiogenic source ($\varepsilon^{i}_{Nd} = 5.4 \pm 0.9$). The high ε^{i}_{Nd} may be an artefact of systematic alteration of Sm–Nd isotopes in the surface samples, but it corresponds with differences in HREE (Fig. 3), which suggest a garnet residue in the Bluebush source but not in the Kambalda source(s). It is most unlikely that the source of even the most depleted samples from the Kambalda sequence could have evolved ^{143}Nd sufficiently rapidly to be the source for Bluebush also, and it is inferred that yet another mantle composition was available at the time that the Bluebush lavas were erupted.

The Kambalda granite

The sodic granite used in the previously-published Sm–Nd isochron for Kambalda has been independently dated at 2,820 ± 15 Myr by U–Pb on zircons[14]. To produce a Sm–Nd isochron by combining this granite with the mafic–ultramafic lavas it intrudes requires the assumption that the felsic samples have the same initial $^{143}Nd/^{144}Nd$ as, and are essentially the same age as, the mafic–ultramafic lavas[4]. However, it is most unlikely that the granite is directly derived from the mantle source of the lavas, and an origin by extreme fractional crystallization from the lavas is also highly unlikely because of the large LREE fractionation required. Thus it is not surprising that the new Sm–Nd isochron for Kambalda, based on lavas alone, does not extrapolate through the granite data (Fig. 2*b*).

Other possible origins for the Kambalda granite are that it represents re-melting of old granite–gneiss basement, or that it derives from a partial melt of older greenstone rocks infolded to great depths. It is possible to choose between these options because the $\varepsilon^{i}_{Nd,t}$ of the granite is independently set at 3.9 ± 0.6 using the zircon age[4,14]. The high ε^{i}_{Nd} raises the paradox that the granite (which is very LREE enriched[4]) was derived from LREE depleted (high Sm/Nd) source, and this does not correspond to known compositions of granite–gneisses in the area[15]. This leaves the possibility that the 2,800 Myr-old granite was melted from pre-existing greenstones. Suitably light-REE enriched liquids would result if such material, in the form of garnet-amphibolite or garnet-granulite, was partially melted at depth[4], and basic–ultrabasic lavas comprising the bulk of this, and other, greenstone belts do have the radiogenic Nd compositions required to form a source for the granite[11–13]. For instance, it could be produced by melting of Kambalda greenstones with average $^{147}Sm/^{144}Nd = 0.2262$, which is close to the mean measured value at Kambalda. This is independent, if indirect, evidence that greenstones much older than the 2,800 Myr-old granite exist in the Yilgarn block.

Crustal evolution

Detailed geochronological studies in the Yilgarn block are sparse, but reported zircon ages of 2,560 ± 30 Myr for some minor felsic dykes, and 2,820 ± 15 Myr for the granite, both at Kambalda[14], are significantly younger than the 3,262 ± 44 Myr-old lavas that they intrude. It has been suggested that

the felsic intrusives are a subvolcanic expression of felsic volcanism higher in the greenstone stratigraphy[16], and a whole-rock Sm–Nd date of 2,780 ± 70 Myr has been reported for felsic volcanics at Kanowna, 60 km north of Kambalda[13]. If all these ages are correct, this implies that development of the greenstone belt extended over a period in excess of 380 Myr and highlights a remarkable lack of recognized unconformities—a paradox that applies to many, if not most, greenstone belts[17].

The regionally extensive banded gneisses, which have been considered as representing the basement to the greenstones[18], have yielded a whole-rock Sm–Nd age of 2,800 ± 100 Myr for localities close to Kambalda[15], and a whole-rock Pb–Pb age of 2,700 ± 97 Myr for samples from widespread localities in the Yilgarn granite–greenstone terrain[19]. These are younger than both the age reported here for the Kambalda greenstones, and a further whole-rock Sm–Nd age of 3,050 ± 100 Myr reported for greenstones in the Diemals–Marda area[13]. This observation does not correspond with simpler models of craton development whereby greenstones are late features deposited on granite–gneiss basement.

Older dates are found in gneisses of the Western Gneiss Terrain, from where zircon dates of $3{,}267^{+48}_{-25}$ Myr for Gabidine Springs and $3{,}341^{+133}_{-73}$ Myr for Windmill Hill, comparable in age to the Kambalda volcanics, have been reported[20]. Attention has recently focused on gneisses near Mount Narryer which have produced whole-rock Rb–Sr and Sm–Nd ages of 3,300–3,600 Myr[21], and in which have been found four detrital zircons yielding near-concordant U–Pb ages between 4,100 and 4,200 Myr (refs 22, 23). Isotopic dates in the Yilgarn block thus cover a period of over 1,500 Myr. Together with the great age of the Kambalda greenstones in relation to associated banded gneisses, this suggests that formation of the early crust in the Yilgarn was a multi-stage process, and more complex models must be sought.

Conclusions

Sm–Nd systematics in rocks from the Kambalda region of the Yilgarn Craton, Western Australia, yield important constraints on the evolution of the Archaean mantle and crust. The paradox of low Sm/Nd but high ε^i_{Nd} in a 2,800 Myr-old granite suggests that it represents a partial melt of older greenstone material rather than granitic gneisses. This indirect clue to the existence of very old greenstones in the Yilgarn is confirmed by the 3,262 ± 44 Myr Sm–Nd age of lavas hosting the Kambalda nickel deposits, which predate gneisses previously proposed as basement rocks. The known development of this section of the Norseman–Wiluna belt is extended to a period of more than 380 Myr.

The lavas at Kambalda may have been derived from at least two sources, with distinct Sm/Nd ratios, that separated from a mantle with $\varepsilon^i_{Nd} = 2.3 \pm 0.2$ immediately before partial melting and eruption. Scatter of data in volcanics from an overlying sequence at Bluebush may reflect disturbance of the Sm–Nd system. However, ε^i_{Nd} is systematically very high for all samples from Ultramafic Hill, and this combines with other characteristics to suggest that a separate part of the mantle was tapped to generate the younger volcanics. A previously-suggested evolution of komatiites with time, from HREE-depleted types to lavas with chondritic ratios of these elements is not confirmed, and it is inferred that a wide variety of mantle compositions was available under the Kambalda region during development of the greenstone belt.

That the Kambalda lavas are apparently 400 Myr older than previous dates from the same greenstone belt[24] is perhaps an artefact of the severe lack of Sm–Nd studies in the area, and the fact that existing chronologies depend on decay schemes such as Rb–Sr, K–Ar and U–Th–Pb, which either have not recorded primary crystallization ages or have only been applied to younger intrusive rocks. However, this study shows that confidence placed in whole-rock isochrons is clouded by little-discussed problems of source heterogeneity and choice of samples. Further detailed applications of Sm–Nd isotopes are required to substantiate this presently anomalous result.

We thank P. Guise and R. Paver for technical assistance, and A. Dunkley for drafting the diagrams. Constructive reviews of an earlier draft were given by A. Cattell, J. Gresham, J. Hallberg, D. Harley, A. Larking, two anonymous reviewers, and by D. Groves who also helped with selection of some samples. We also thank Western Mining Corporation for access to the area, many useful discussions, and permission to publish the data. Isotope and REE research at Leeds is funded by NERC and the Royal Society; J.C-L. and R.W.N. acknowledge support from NERC grants GT4/80/GS/102 and GR3/4437 respectively.

Alteration of c-*myc* chromatin structure by avian leukosis virus integration

William Schubach* **& Mark Groudine†**

Hutchinson Cancer Research Center, 1124 Columbia Street, Seattle, Washington 98014, USA
† Department of Radiation Oncology, University of Washington Hospital, Seattle, Washington 98015, USA

*The most common sites of integration of the leukosis virus (ALV) long terminal repeat (LTR) in bursal lymphomas and derivative cell lines correspond to a region encompassed by two major hypersensitive sites in the 5′ flanking region of the pre-integration, unrearranged c-*myc *gene. After integration of the ALV LTR, the major hypersensitive site within the avian c-*myc *oncogene region is within the proviral LTR, and the major hypersensitive sites normally found in uninfected cells 5′ to the first c-*myc *coding exon are no longer detectable.*

DIFFERENTIAL sensitivity to DNase I distinguishes the chromatin structure of genes that are actively transcribed from those that are inactive[1]. In addition, specific DNase I hypersensitive sites have been found in a variety of systems, predominantly near the 5′ ends of actively transcribed genes (refs 2–8; see also ref. 9 for a review). In some cases, these sites appear with the developmentally regulated transcriptional activation of specific genes[4–6], and in other systems, their appearance precedes the activation of gene expression[7,8]. Hypersensitive sites have also been detected within certain regulatory sequences in DNA, such as the long terminal repeats (LTRs) of transcribed avian endogenous provirus[10,11], the 72 base pair (bp) repeat involved in enhancement of simian virus 40 (SV40) gene expression[12,13], and an enhancer complex located upstream from an actively transcribed glue protein gene in *Drosophila*[14,15]. It is possible that the local alteration in chromatin structure revealed by DNase I hypersensitivity is related to the apparent enhancer function of these elements.

There is also indirect evidence that DNase I hypersensitivity characterizes regions involved in targeted recombination. In yeast mating-type interconversion, a specific and genetically regulated DNase I hypersensitive site corresponds to the site of a double-strand endonucleolytic cleavage that is destined to be the recipient site in the active cassette[16]. Also, in T lymphocytes, a cluster of DNase I hypersensitive sites occurs within a span of several kilobases between joining (J) and heavy chain (C_H) genes in the region involved in heavy chain switching in B lymphocytes[17].

To understand the possible relationships among hypersensitive sites, 'enhancement' and recombination, we studied the DNase I hypersensitivity pattern upstream from the cellular oncogene of chickens, c-*myc*. c-*myc* is the endogenous cellular homologue of the transforming gene (v-*myc*) of the avian myelocytomatosis virus, MC29[18–20]. In bursal lymphomas induced by the avian leukosis virus (ALV), integration of the ALV provirus in the region of c-*myc* has been shown to enhance significantly transcription of the c-*myc* gene[21]. In addition, rearrangements around c-*myc* in B-cell tumours of other species have been described. For example, in mouse myeloma[22,23] and in Burkitt's lymphoma[24–27] cell lines translocations involving immunoglobulin genes and c-*myc* are associated with altered c-*myc* transcription. Thus, we felt a study of the chromatin structure around the c-*myc* oncogene prior to and after LTR integration into this locus might provide insight into amplified or altered gene expression in bursal lymphomas. This was facilitated by the isolation of bursal lymphoma cell lines haploid for c-*myc*, containing only a single c-*myc* allele associated with an upstream ALV proviral LTR. Thus, the chromatin structure of the normal, unrearranged c-*myc* locus does not interfere with the analysis of the structure of the LTR-associated c-*myc* chromosomal domain. Our results show that after the integration of the ALV LTR, the major hypersensitive site within the c-*myc* region usually occurs within the proviral LTR, and the major hypersensitive sites normally found in uninfected cells 5′ to the first c-*myc* exon are no longer detectable. Also, we find that the most common sites of integration of the ALV LTR in bursal lymphomas and derivative cell lines correspond to a region encompassed by two major hypersensitive sites in the 5′ flanking region of the unrearranged c-*myc* gene.

Mapping hypersensitive sites

The presence and location of hypersensitive sites in the c-*myc* locus were determined by treating nuclei of various tissues obtained from embryonic and young chicks with increasing concentrations of DNase I for brief periods of time. DNA isolated from these nuclei was subsequently digested with restriction endonuclease, electrophoresed on agarose gels and blot hybridized to nick-translated probes derived from a genomic clone of the c-*myc* region. In this analysis, hypersensitive sites are manifest as DNase I generated sub-bands, one end of which is defined by the restriction enzyme recognition site and the other by the DNase I hypersensitive site.

Figure 1 shows the results of this type of analysis of nuclei derived from 14-day embryonic red blood cells (RBC) and a bursa from a 4-week post-hatching chicken. In Fig. 1*a*, RBC nuclei were digested with DNase I, and the DNA was isolated and digested with *Sst*I, 'Southern' blotted and probed with the 9.2-kilobase (kb) λ-*myc* probe depicted at the bottom of the figure. This probe includes the coding and 5′ flanking sequences of the c-*myc* region. In addition to the 7.3-kb *Sst*I parent fragment, two additional bands of 4.8 and 5.8 kb are generated by DNase I. Extensive mapping of these sub-bands has revealed two hypersensitive sites (designated II and III in Fig. 1*a*) upstream from c-*myc*. The 3.2-kb *Sst*I band, which encompasses the c-*myc* coding region, is very sensitive to digestion by DNase I since it is smaller and disappears before the sub-bands.

Because *Sst*I cleaves 190 bp downstream from the identified 5′ coding sequences of c-*myc*[28], it is not a suitable restriction enzyme for defining hypersensitive sites close to the 5′ end of this coding region. Thus, we used the indirect end-labelling approach of Wu[2], in which a probe is used that hybridizes to that end of the sub-band defined by the restriction endonuclease recognition site. With this approach, the location of DNase I hypersensitive sites can be inferred directly from the length of the sub-bands generated. Nuclei from a 4-week bursa were digested with increasing concentrations of DNase I, restricted with *Cla*I and *Bam*HI, Southern blotted, and hybridized to a 1,050-bp probe the 3′ end of which is defined by the *Cla*I site and which spans the c-*myc* intron indicated in the map below

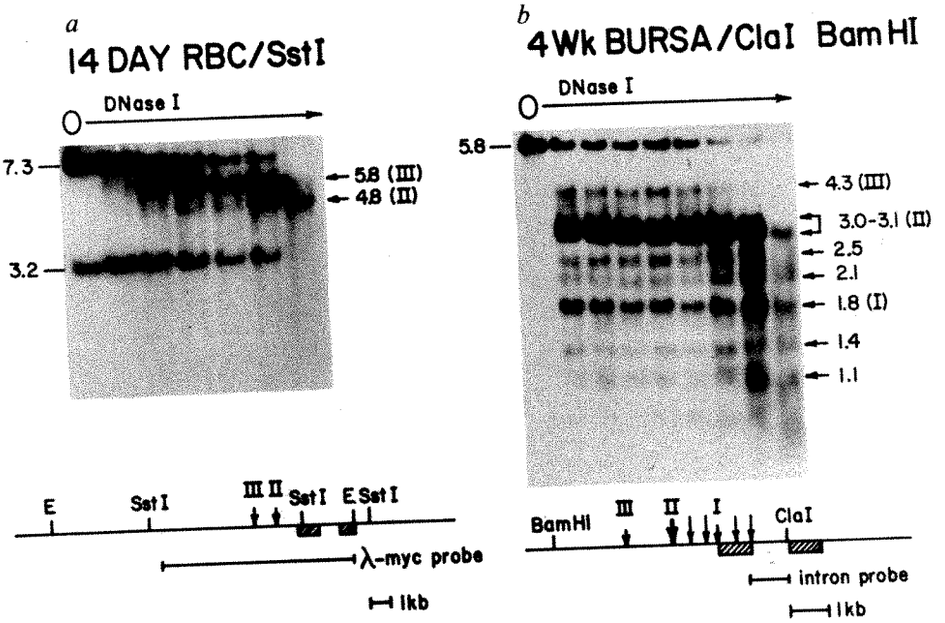

Fig. 1 Endogenous DNase I hypersensitive sites upstream from c-*myc*. Nuclei from designated tissues were digested with increasing concentrations of DNase I (as designated by the direction of the arrow), DNA isolated, digested with the enzymes denoted, and subjected to blot hybridization following electrophoresis in 1% agarose gels. The blots were probed with the nick-translated probes designated below the autoradiograms. Nuclear isolation, DNase I digestion of nuclei, DNA purification, restriction enzyme digestion and blot hybridization were performed as described previously[4,5,8]. All probes described in this and subsequent figures containing c-*myc* sequences were derived from a λ clone containing a 9.2-kb insert with sequence homology to v-*myc*, isolated from a chicken genomic library[47] by conventional screening methods[48]. Plasmid subclones were prepared using the pBR322 analogue pSV2 (obtained from B. Seed). Published data[28,30,49] have been used to correlate specific fragments with intron and exon positions. λ-*myc* is a 9.2-kb *Eco*RI fragment with an artificial R1 site at the 5′ end and a 3′ end that is the *Eco*RI site at the 3′ side of the second c-*myc* exon. 'Intron' is a 1-kb *Sal*I–*Cla*I fragment that includes primarily the intron of c-*myc*. Fragments were isolated from their host-vector sequences by restriction enzyme digestion, agarose gel electrophoresis, isolation in hydroxyapatite troughs[50] and nick-translated[51]. Restriction sites are marked; E, *Eco*RI. *a*, Four week RBC were digested with *Sst*I and hybridized to the λ-*myc* probe. A 3-kb *Sst*I band detected by this probe is very sensitive to DNase I. A parent band of 7.3 kb and sub-bands of 5.8 and 4.8 kb are seen corresponding to the hypersensitive sites III and II in the diagram at the bottom of the figure. *b*, Normal 4-week bursa DNA digested with *Cla*I plus *Bam*HI and analysed using the 1-kb intron probe depicted at the bottom of the figure. A parent fragment of 5.8 kb and sub-bands corresponding to the arrows are seen. See text for details.

Fig. 1*b*. Figure 1*b* shows that *Cla*I/*Bam*HI digestion of normal bursa DNA reveals a parent band of 5.8 kb and DNase I-generated sub-bands of 4.3, 3.0–3.1, 2.5, 2.1, 1.8, 1.4 and 1.1 kb; arrows show positions of the specific DNase I hypersensitive sites in c-*myc* from which these sub-bands are generated. Since the *Cla*I site is 1.8 kb from the 5′ side of the first c-*myc* exon[28], and the 3′ end of the probe is defined by this *Cla*I site, we can determine fairly accurately the positions of these hypersensitive sites relative to the 5′ side of the first c-*myc* exon. A prominent hypersensitive site lies 1.2–1.3 kb upstream from the first exon (site II). Less prominent, but distinct sub-bands lie at the end of the first exon (site I) and 2.5 kb upstream from the first exon (site III). Minor DNase I hypersensitive sites lying between I and II, at the 3′ end of the first exon, and within the intron are also designated in Fig. 2*b* by arrows. These latter sites vary in intensity and appearance in different nuclear preparations.

Results comparable with those in Fig. 2*b* were obtained for 14-day embryonic RBC and yolk sac cells, and bursa, thymus, liver, brain, bone marrow, muscle and spleen from a 4-week-old chick, as well as cultured chick embryonic fibroblasts (CEF), Rous sarcoma virus (RSV)-transformed CEF and MSB cells[29]. In addition, when the same blots are probed with sequences from a gene known to be inactive in these tissues (for example, a probe for sequences flanking the endogenous retroviral locus *ev*-1), no hypersensitive sites are seen, and the *ev*-1-containing sequences are less sensitive to DNase I than c-*myc* coding sequences (data not shown). Thus three prominent DNase I hypersensitive sites, denoted I, II and III, lie upstream from c-*myc* in the chromatin from the majority of chicken tissues studied at these stages of development, and the c-*myc* sequences appear to be in an active chromatin structure in all of these cells.

Cell lines: restriction mapping

We have analysed the restriction sites and mapped the location and orientation of the LTR for five bursal lymphoma cell lines. The data and results of this analysis are presented in Fig. 2, and for comparison the restriction map of the c-*myc* region of normal chicken DNA[30] is included in Fig. 2*b*.

Figure 2*a* shows the analysis of DNA from a diploid bursal lymphoma cell line, BK3A. When DNA from these cells is digested with *Eco*RI and probed with the c-*myc* probe (shown at the bottom of Fig. 2*b*), three bands are generated: the 14- and 20-kb bands correspond to fragments that flank the *Eco*RI site in the 'normal' c-*myc* allele. A third 3.7-kb fragment is generated by the introduction in an ALV LTR upstream from c-*myc* due to the presence of an *Eco*RI site in the U3 region of the LTR[31]. Since this band is detected by a probe for sequences of the U5 region of the LTR, but not by a probe for U3 sequences (Fig. 2*a*), this 3.7-kb tumour-specific junction fragment demonstrates that an LTR is located 1.0 kb upstream from the first major c-*myc* exon in the same transcriptional orientation as c-*myc*. This arrangement has been confirmed by digestion with *Bam*HI, *Sst*I and *Sal*I and probing with defined segments of c-*myc* and the ALV genome (not shown). Double digestion of BK3A with *Bam*HI plus *Sal*I and probing with the 5′ exon of c-*myc* confirms the arrangement of LTR and c-*myc* sequences in BK3A cells (Fig. 2*b*).

The same analyses were performed for the biologically cloned cell lines BK25 and 1104HI, and these results are illustrated in Fig. 2*a*. In both cases digestion with *Eco*RI generates only one band that is detected by probes for both c-*myc* and 5′ LTR sequences. The higher molecular weight *myc* bands are not seen, and *Bam*HI/*Sal*I double digestion detects only one band containing 5′ exon sequences. Thus, these cells contain only one c-*myc* allele, the one associated with a nearby LTR, the 'normal' c-*myc* allele having been lost. In BK25 cells, the LTR lies within 0.1–0.2 kb of the first c-*myc* exon, and in 1104HI the LTR lies 1.2 kb upstream from the first c-*myc* exon. In both cases, the LTR is in the same transcriptional orientation as c-*myc*, as depicted in Fig. 2*b*.

A similar analysis of a subclone from the 1104B1 cell line, 1104BI S13, is depicted in Fig. 2*a*. In this case, *Eco*RI yields a single band of 5.4 kb that hybridizes to c-*myc* and 3′ LTR, but not 5′ LTR probes. Thus, in this cell line, the LTR and contiguous c-*myc* sequences lie in opposite transcriptional orientations, and only the LTR-associated c-*myc* locus is present.

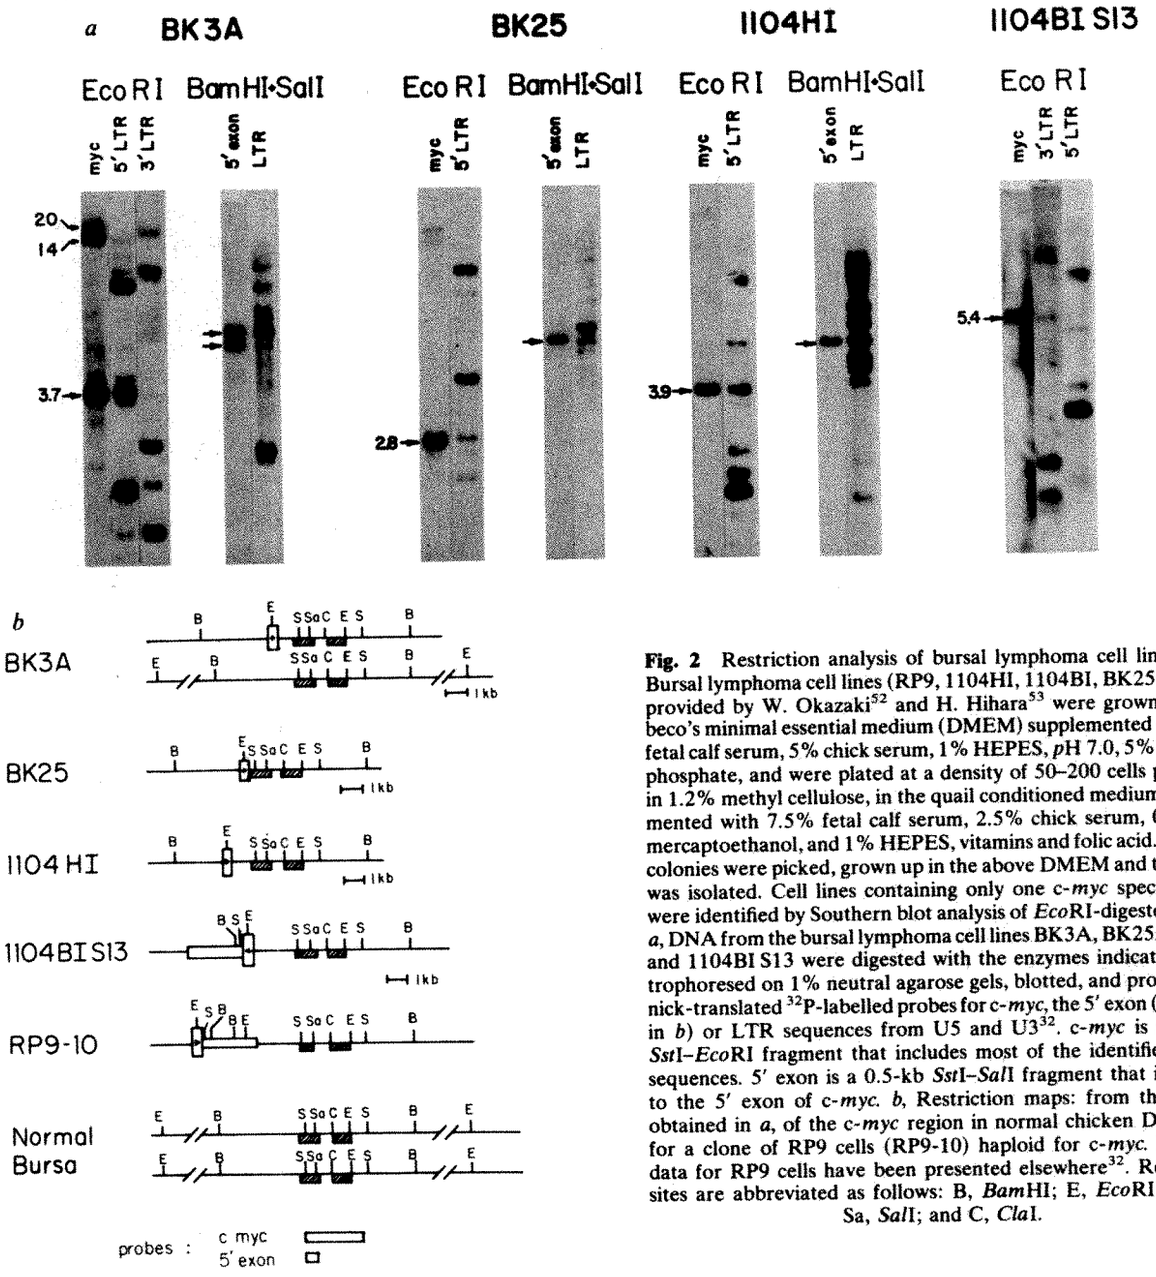

Fig. 2 Restriction analysis of bursal lymphoma cell line DNA. Bursal lymphoma cell lines (RP9, 1104HI, 1104BI, BK25, BK3A) provided by W. Okazaki[52] and H. Hihara[53] were grown in Dulbecco's minimal essential medium (DMEM) supplemented with 5% fetal calf serum, 5% chick serum, 1% HEPES, *p*H 7.0, 5% tryptose phosphate, and were plated at a density of 50–200 cells per plate in 1.2% methyl cellulose, in the quail conditioned medium supplemented with 7.5% fetal calf serum, 2.5% chick serum, 0.15 mM mercaptoethanol, and 1% HEPES, vitamins and folic acid. Isolated colonies were picked, grown up in the above DMEM and the DNA was isolated. Cell lines containing only one c-*myc* specific band were identified by Southern blot analysis of *Eco*RI-digested DNA. *a*, DNA from the bursal lymphoma cell lines BK3A, BK25, 1104HI and 1104BI S13 were digested with the enzymes indicated, electrophoresed on 1% neutral agarose gels, blotted, and probed with nick-translated ^{32}P-labelled probes for c-*myc*, the 5′ exon (depicted in *b*) or LTR sequences from U5 and U3[32]. c-*myc* is a 2.4-kb *Sst*I–*Eco*RI fragment that includes most of the identified c-*myc* sequences. 5′ exon is a 0.5-kb *Sst*I–*Sal*I fragment that is unique to the 5′ exon of c-*myc*. *b*, Restriction maps: from the results obtained in *a*, of the c-*myc* region in normal chicken DNA, and for a clone of RP9 cells (RP9-10) haploid for c-*myc*. Mapping data for RP9 cells have been presented elsewhere[32]. Restriction sites are abbreviated as follows: B, *Bam*HI; E, *Eco*RI; S, *Sst*I, Sa, *Sal*I; and C, *Cla*I.

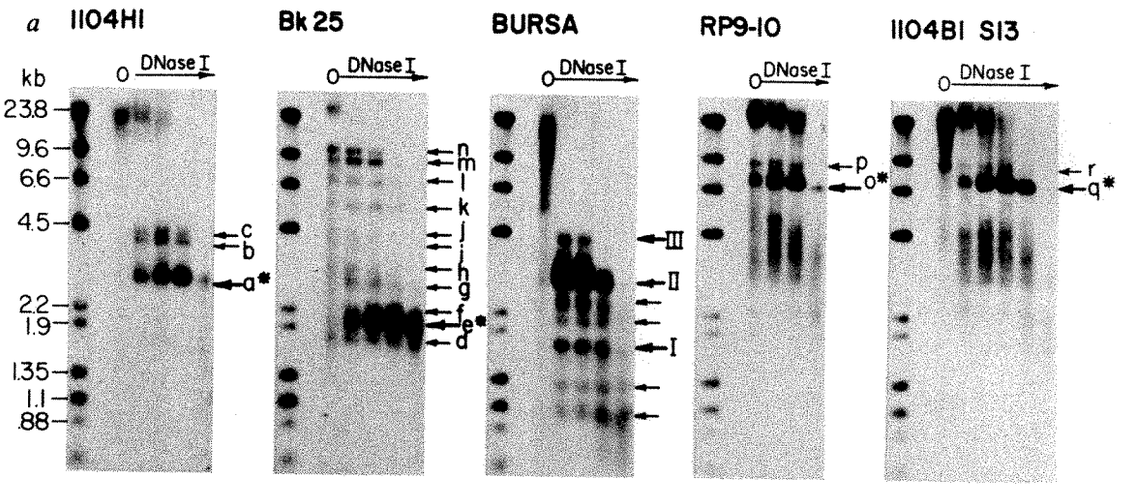
Preliminary restriction analysis (in collaboration with M. Linial) of the *myc* region in this subclone shows that there are approximately 2.5 kb of proviral sequences inserted 2.6–2.7 kb upstream from the first c-*myc* exon (Fig. 2*b*).

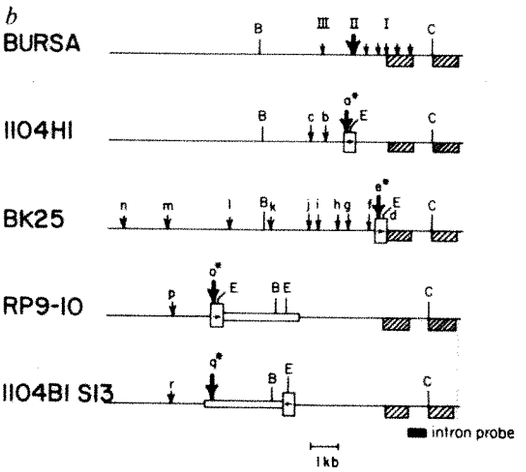
When RP-9 cells are biologically cloned, clones containing only the c-*myc* allele and upstream proviral sequences are obtained. The restriction map of one such clone, RP9-10, is shown in Fig. 2*b*. Detailed mapping of c-*myc* in RP-9 cells has been presented elsewhere[32]. Essentially, this clone contains approximately 2.5 kb of proviral information consisting of a complete LTR and *gag* gene and part of *pol* gene, inserted 2.5–2.6 kb upstream from the first c-*myc* exon. The proviral sequences and c-*myc* are in the same transcriptional orientation (Fig. 2*b*).

Cell lines: chromatin structure

In most bursal lymphomas induced by ALV, the proviral LTR is integrated upstream from c-*myc* such that regulatory sequences in the LTR act directly to promote or otherwise enhance transcription of c-*myc*[21,33–35]. In addition to these types of integrations which are consistent with a downstream promoter model for the LTR activation of c-*myc*[21], enhanced c-*myc* expression has been reported in bursal lymphomas in which the LTR is located downstream from c-*myc* or upstream from c-*myc* in the opposite transcriptional orientation[36]. Since retroviral LTRs or analogous elements have been found to have an enhancer function distinct from that associated with downstream promotion[37–39], and because DNase I hypersensitive sites are associated with enhancer sequences in SV40 chromatin[12,13] and the *Drosophila Sgs*4 gene[14], we asked whether the introduction of an LTR upstream from c-*myc* altered the pattern of DNase I sensitivity that we observed in uninfected tissues. Such an analysis is difficult in tumours where c-*myc* is diploid. One locus contains a nearby LTR and one does not. Thus, there is both a 'normal' allele containing the family of endogenous hypersensitive sites, and an 'activated' allele containing an LTR and any alteration of this endogenous pattern of chromatin structure that the LTR might introduce. Our analysis has been facilitated by the isolation of the biologically cloned bursal lymphoma cell lines described above (Fig. 2*b*) which contain only the LTR-associated c-*myc* allele.

The distribution of DNase I hypersensitive sites in these cell lines compared with that in normal bursa is shown in Fig. 3. Normal bursal DNA taken from DNase I-treated nuclei (as used





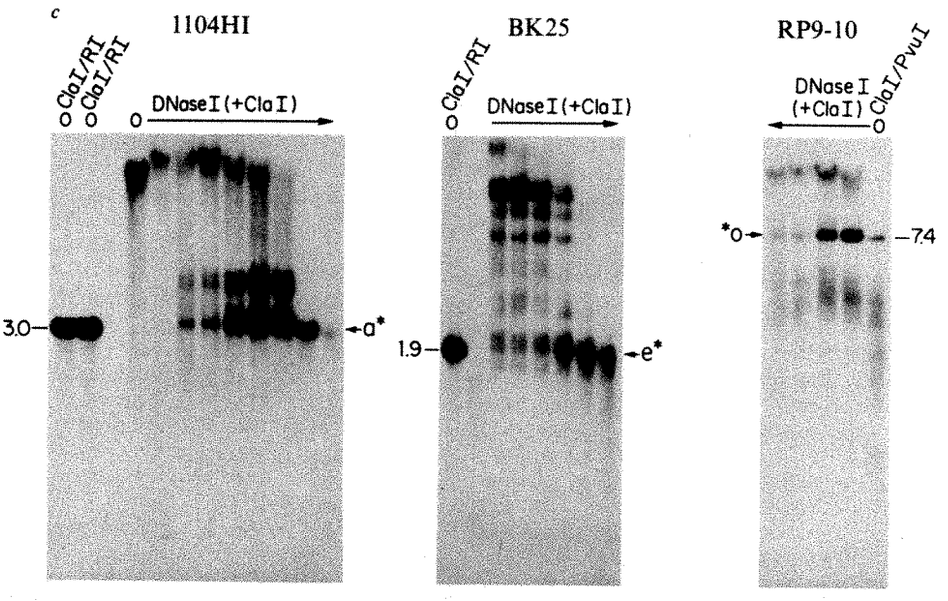


Fig. 3 Effect of LTR integration on chromatin structure upstream from c-*myc*. ***a***, Nuclei from normal bursa or the c-*myc* haploid cell lines indicated were digested with DNase I, DNA isolated, restricted with *Cla*I, blotted, and probed with the intron probe. All data presented in this figure were derived from a single blot of a large gel that contained all the samples. This was done to facilitate comparison of the locations of sub-bands in the various DNase I 'series'. Sub-bands are designated by arrows and letters to the right of each series. The major sub-band in each series is indicated by a bold arrow and an asterisk. Note that some sub-bands are present in the '0' (undigested with DNase I) DNA, a variable finding reported by several investigators[7]. The molecular weight markers are a combination of ^{32}P-labelled *Hin*dIII-digested DNA and *Hae*III-digested ϕXRF DNA. In the normal bursa series, the major sub-bands are indicated by roman numerals, as in Fig. 1. In the case of BK25, we have indicated all sub-bands seen in any of the multiple DNase I series we have performed, even though 'g' to 'j' sub-bands are rarely observed to contain significant signal. ***b***, Locations of the hypersensitive sites detectable by the analysis presented in Fig. 3*a* are superimposed upon the restriction maps of these cell lines and normal bursa DNA. As in Fig. 3*a*, the hypersensitive sites observed in the cell lines are indicated by arrows and letters, with the major hypersensitive sites indicated by bold arrows and asterisks. The locations of the normal bursa hypersensitive sites are included for comparison. ***c***, Locations of the major hypersensitive sites present in 1104HI, BK25 and RP9-10 are compared with the location of specific restriction enzyme recognition sites in the upstream LTR. For 1104HI and BK25, the *Cla*I digestions of DNase I series are compared with *Cla*I/*Eco*RI doublet digests of DNA, whereas for RP9-10, a *Cla*I-digested DNase I series is compared with a *Pvu*I/*Cla*I double digest of DNA. See text for rationale and details of this analysis. All blots are hybridized by the intron probe.

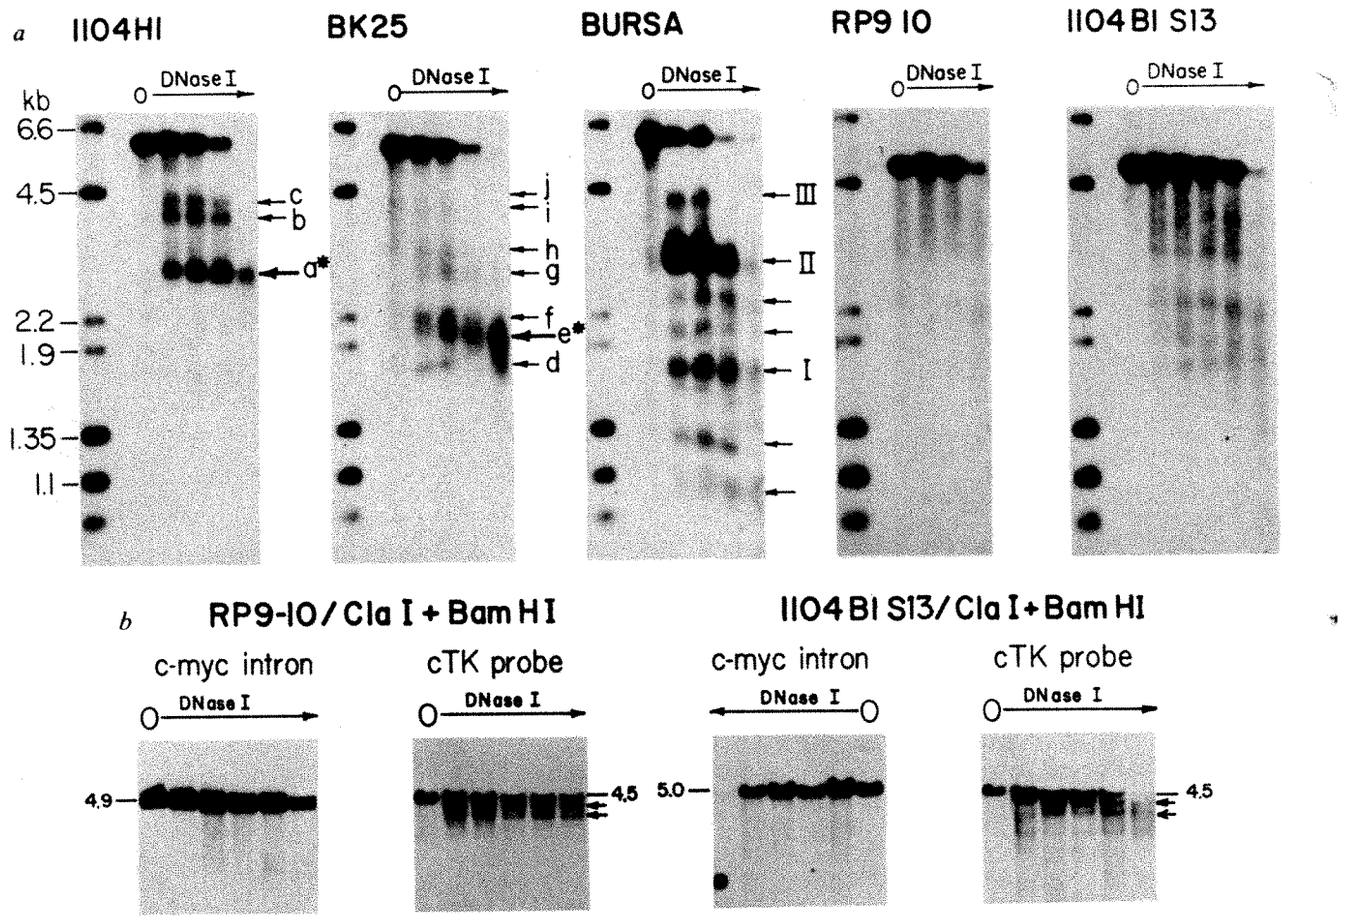

Fig. 4 Suppression of normal c-*myc* hypersensitive sites is associated with the upstream insertion of proviral sequences in different transcriptional orientations. *a*, DNA from the DNase I 'series' described in Fig. 3*a* was digested with *Cla*I plus *Bam*HI, blotted and hybridized to the intron probe. As described in Fig. 3*a* legend, all of these samples were loaded on the same gel and transferred to a single blot, to facilitate comparison. Arrows, letters, roman numerals and molecular weight markers are as for Fig. 3*a*. *b*, DNA derived from DNase I-digested nuclei of RP9-10 (a different preparation from that illustrated in Figs 3*a* and 4*a*) and 1104B1 S13 were restricted with *Cla*I and *Bam*HI, blotted and hybridized to either the c-*myc* intron probe or a probe for the chicken thymidine kinase (*tk*) gene (a generous gift of M. Wigler). While no hypersensitive sites are apparent in these digests with the intron probe, two prominent hypersensitive sites (arrows to the right of the blots) are seen with the *tk* probe.

in Fig. 1) was digested with *Cla*I, Southern blotted, and probed with the intron probe (Fig. 3*a*). The results of such digests confirm the observations described above concerning the presence and location of hypersensitive sites upstream from c-*myc*. DNAs from DNase I-treated nuclei isolated from 1104HI and BK25 were digested with *Cla*I and probed with the intron probe. Applying the same reasoning used in the analysis of normal bursa in Fig. 2, this will define DNase I-hypersensitive sites upstream from c-*myc* in these cell lines. As shown in Figs 3*a* and schematically in 3*b*, prominent DNase I hypersensitive sites occur near the *Eco*RI site in the LTR of these cell lines (sites a* and e* in Fig. 3*a* and 3*b*). That these hypersensitive sites reside in the LTR is also suggested by the results presented in Fig. 3*c*. In this figure the sub-bands, generated by *Cla*I digestion of the DNA from DNase I-treated nuclei of these cell lines, are compared to control DNA from these cell lines that has been digested with *Cla*I and *Eco*RI. Since *Eco*RI cleaves within the LTR, the *Cla*I/*Eco*RI band defines the location of the LTR relative to c-*myc* in these cells. By this analysis, the hypersensitive site lies about 0.1 kb upstream from the *Eco*RI site, near position 100 of the LTR (±60 bp)[31,40]. Rehybridization of the blot with probes specific for the U5 and U3 regions of the LTR has confirmed the location of this site within the LTR (not shown).

A similar analysis was performed for another haploid cell line RP9-10. These cells are unusual in that they contain a large amount of proviral DNA upstream from c-*myc*, including *gag* sequences that contain an *Eco*RI site. Thus, in this analysis, the *Pvu*I site unique to LTR sequences[40] was used to define the location of the LTR. Upon *Cla*I digestion of a DNase series from RP9-10 cells, a sub-band of 7.5 kb (site o* in Fig. 3*a*, *b*) is seen that corresponds rather closely to the location of the LTR in these cells, as defined by *Pvu*I/*Cla*I double digest of control RP9-10 DNA. This analysis and extensive mapping, using a variety of restriction endonucleases and cellular and proviral probes (not shown), places the hypersensitive site approximately 0.1 kb upstream from position 39 of the LTR.

In 1104BI S13 cell line, in which the LTR has inserted in the opposite transcriptional orientation, 2.7 kb upstream from the 5′ end of c-*myc*, *Cla*I digestion of DNase I-treated nuclear DNA and hybridization to the intron probe demonstrates a sub-band of approximately 7.5 kb (Fig. 3*a*, sub-band q*, Fig. 3*b*, site q*). After *Cla*I digestion, this same 7.5-kb sub-band is detected when the blot is rehybridized to several proviral sequence-specific probes, but not by a probe for cellular sequences 5′ to the integrated provirus (not shown), indicating that the site resides in proviral sequences. Thus, although no hypersensitive site is present in the c-*myc* associated LTR in these cells, a new proviral-associated hypersensitive site has been introduced into this locus by the insertion of proviral sequences. Hypersensitive sites located in proviral sequences other than LTRs have been observed previously in avian retroviruses[11]. Interestingly, as can

be seen in Fig. 3*a* and *b*, the provirus-associated hypersensitive sites in RP9-10 and 1104BI S13 (o* and q*, respectively) are in similar locations relative to c-*myc*, even though the proviruses are integrated in opposite orientations. Similarly, sites 'p' in RP9-10 and 'r' in 1104BI S13 which are absent in normal bursa (Fig. 3*b*), are located in comparable regions upstream from the provirus in these cell lines.

Newly integrated proviral sequences appear to affect the local structure of chromatin in surrounding cellular sequences. For example, none of the hypersensitive sites characteristic of the c-*myc* region in normal cells is observed in the RP9-10 cell line upon digestion of DNase I-treated nuclear DNA with *Cla*I (Fig. 3*a*). Since the LTR hypersensitive site is apparent in the RP9-10 chromatin, the lack of the normal c-*myc* sites is not a consequence of our failure to digest these nuclei in a fashion sufficient to detect these sites. Digestion of these same DNA samples with *Cla*I and *Bam*HI (*Bam*HI cleaves within the *gag* region of the provirus, downstream of the LTR; see Fig. 2*b*), and hybridization to the c-*myc* intron probe, confirms the absence of hypersensitive sites in the c-*myc* region between the newly integrated proviral DNA sequences and the first c-*myc* exon (Fig. 4*a*). In contrast, multiple hypersensitive sites are seen in bursa, 1104HI and BK25 when DNA from DNase I-digested nuclei from these cells is digested with *Cla*I and *Bam*HI and blot hybridized to the intron probe (Fig. 4*a*). The absence of these sites in RP9-10 is also seen in a *Cla*I/*Bam*HI digestion of an expanded DNase I series from another preparation of these cells (Fig. 4*b*). As a control, multiple hypersensitive sites around the chicken thymidine kinase (*tk*) gene are detected when this blot is rehybridized to a TK probe (Fig. 4*b*). A similar loss of the normal c-*myc* hypersensitive sites is observed in the 1104B1 S13 cell line when DNA from the DNase I-treated nuclei of these cells is digested with *Cla*I (Fig. 3*a*) or *Cla*I and *Bam*HI (Fig. 4*a* and *b*) and the subsequent blots are hybridized to the c-*myc* intron probe. As described above, in 1104B1 S13 the proviral sequences are inserted in the 'opposite' orientation; thus, the *Bam*HI site is in the *gag* gene, downstream from the newly introduced hypersensitive site in this cell line, and defines the 5′ end of the *Bam*HI/*Cla*I parent fragment (see Fig. 2*b*). As in the case of the RP9-10 samples, when the 1104BI S13 blot is rehybridized to the *tk* probe, multiple hypersensitive sites are detected (Fig. 4*b*). Thus, in both of these cell lines, the integration of proviral sequences appears to alter the endogenous structure of the c-*myc* locus, as shown by the loss of DNase I-hypersensitive sites downstream from the newly integrated proviral sequences, and the introduction of new hypersensitive sites into this chromosomal domain.

The analysis of the effect of proviral insertion on the endogenous c-*myc* chromatin structure in the BK25 and 1104HI cell lines is more complex than that for RP9-10 and 1104BI S13, due to the position of insertion of the LTRs in two former cell lines. As described above, both of these cell lines contain hypersensitive sites in the LTR upstream from the first c-*myc* exon (sites a* and e*). In 1104HI, the LTR hypersensitive site is approximately 1.2 kb upstream from the 5′ end of c-*myc* and in BK25, the LTR site is approximately 100 bases upstream from c-*myc*. Since in both cell lines, approximately 350 bp of proviral information has been inserted, the major endogenous site found in normal cells, which usually resides at 1.2 kbp upstream from the 5′ end of c-*myc*, would be displaced to approximately a position 1.55 kbp upstream of c-*myc*, and appear as a sub-band in a *Cla*I or *Cla*I/*Bam*HI digest of BK25 and 1104HI of 3.3–3.4 kbp (1.55 kbp+1.8 kbp from the *Cla*I site to the 5′ end of the first c-*myc* exon). As is evident in Fig. 3*b* and *c*, no such sub-band is observed in either cell line. In 1104HI, two additional hypersensitive sites located upstream from the LTR are revealed. The sizes of these sub-bands localize them to 2.3 and 1.8 kbp 5′ to c-*myc*. While it is possible that the latter sub-band could correspond to the normal, major site (if our measurements are in error by ±300 bp), we feel this is unlikely. Clearly, however, the complexity of sites seen in the normal c-*myc* chromosomal domain are absent in the 1104HI cells. In BK25, multiple hypersensitive sites are observed upstream from the LTR insertion (Fig. 3*a*, *b*, *c*). As in 1104HI, however, none of these map to the locations of the major sites observed prior to the LTR insertion. Thus, in both of these cell lines, insertion of a proviral LTR is associated with the introduction of a new hypersensitive site within the proviral sequences, as well as the suppression of some endogenous c-*myc* hypersensitive sites and the uncovering of other 'cryptic' sites in the 5′ flanking region of the c-*myc* gene.

Discussion

We have described the normal pattern of DNase I hypersensitive sites that lie upstream from c-*myc* in normal chicken cells. Major DNase I hypersensitive sites lie near the beginning of the coding region (site I), and 1.2 (site II) and 2.5 kb (site III) upstream from the coding region in every tissue from the various stages of chicken development we have thus far investigated. Interestingly, several investigators have observed a nonrandom distribution of integration sites of the LTR upstream from c-*myc* (refs 32–36, and W. Hayward, personal communication), most lying within an interval of 1.2 kb upstream from the coding region, a region flanked by the DNase I-hypersensitive sites I and II found in normal bursa. These findings raise the possibility that the chromatin in this local region may assume a conformation (as determined by DNase I sensitivity) preferentially targeted for integration within the c-*myc* domain. Clearly, however, we cannot eliminate the possibility that integration occurs in a random fashion in the c-*myc* region, with those insertions at specific sites (for example, upstream from splice donor sequences[30]) giving these cells a selective growth advantage.

The identification of bursal lymphoma cell lines that are haploid at the c-*myc* locus has allowed us to examine the effects of integration of an ALV proviral LTR in this region. In all of these lines a DNase I hypersensitive site can be identified within the proviral sequences integrated upstream from c-*myc*. In three cases (RP9-10, BK25, 1104HI) the hypersensitive site is located between positions 25 and 150 of the LTR, a region associated with enhancement of gene expression in injected and transfected *in vitro* constructs[38,39]. In RP9 cells, a transcript containing proviral and c-*myc* sequences has been described[32], indicating that the LTR is acting as a downstream promoter in these cells. However, in 1104HI and BK25, the amplified c-*myc* transcripts lack LTR sequences[32]; thus, in these cases, the observed enhancement of c-*myc* expression does not appear to be the result of downstream promotion, and probably reflects an enhancing effect of the LTR. These results suggest a correlation between those sequences which have enhancer function and the location of the DNase I hypersensitive site in the LTR.

In 1104BI S13 cells, the LTR lies 2.7 kb upstream from c-*myc* in the opposite transcriptional orientation and does not contain a prominent DNase I hypersensitive site as seen in the other cell lines. Despite this, c-*myc* expression is enhanced to high levels and the transcript is identical in size to the normal 2.5-kb transcript identified in fibroblasts[19] and does not contain proviral sequences (M. Linial, personal communication). Thus, in these cells either the LTR or some other proviral sequence is acting as an enhancer over a remote distance[38,41–43]. Are enhancer sequences and hypersensitive sites, in fact, related? One interpretation of the 1104BI S13 data would be that the enhancer resides in the LTR upstream from c-*myc*, but it lacks a hypersensitive site, possibly due to minor sequence changes. Alternatively, the enhancer in these cells may reside in the proviral sequences defined by the hypersensitive site upstream from the LTR. The latter interpretation would suggest that proviral sequences outside the LTR may contain an enhancer that can be functionally recruited when the enhancer in the LTR is defective, or which is 'dominant' to the LTR enhancer sequences. These possibilities can be tested in various ways using cloned fragments encompassing c-*myc* and proviral sequences from these cell lines.

The data in Figs 3 and 4 suggest that the introduction of proviral sequences upstream from c-*myc* alters the pattern of

endogenous DNase I hypersensitive sites normally found in the upstream region of c-*myc* in uninfected cells. The prominent hypersensitive site 1.2 kb upstream from the coding region (Site II), as well as the other 'minor' sites, are much reduced or absent in RP9-10 and 1104BI S13 cells. In BK25 and 1104HI, the LTR is inserted between the major endogenous c-*myc* hypersensitive site (1.2 kbp upstream from the 5′ exon) and the 5′ exon; this insertion is associated with the loss of this major endogenous hypersensitive site, as well as the acquisition of new sites within the LTR, and the uncovering of some additional sites in cellular sequences upstream to the insertion sites. The above results raise the possibility that the local alterations of chromatin structure associated with the insertion of the LTR or other proviral sequences may affect the transcriptional activity of c-*myc*. For example, one possibility is that specific sequences within the LTR act as dominant 'sinks' of superhelical torsional stress in the DNA of the c-*myc* locus (see refs 44–46 for discussion of this concept), assayable as DNase I hypersensitive sites. In this view, the loss of the major endogenous c-*myc* hypersensitive site would be the consequence of the reversion of these cellular sequences to the 'normal' B form. Within the context of transcriptional enhancement, the LTR-associated hypersensitive site may represent a conformation of DNA which provides a more efficient entry site than the endogenous c-*myc* hypersensitive site for various transcriptional factors, or may provide a novel nucleation site for the positioning of nucleosomes in this region. This latter possibility could also result in the alteration of the pattern of hypersensitive sites in the c-*myc* locus.

We thank Mary Peretz and Angela Hein for technical assistance, Helen Devitt for typing the manuscript, and our colleagues for their comments, especially M. Linial who isolated and helped characterize one cell line and P. Neiman for his support. M.G. is a Scholar of the Leukaemia Society of America. Induction of altered chromatin structures by simian virus 40 enhancer and promoter elements

Jan Jongstra, Tim L. Reudelhuber, Pierre Oudet, Christophe Benoist, Chi-Bom Chae, Jean-Marc Jeltsch, Diane J. Mathis & Pierre Chambon

Laboratoire de Génétique Moléculaire des Eucaryotes du CNRS, Unité 184 de Biologie Moléculaire et de Génie Génétique de l'INSERM, Faculté de Médecine, 11 rue Humann, 67085 Strasbourg Cedex, France

Two simian virus 40 transcriptional promoter elements, the 72-base pair (bp) repeat and the 21-bp repeat region, induce chromatin structures of increased DNase I sensitivity when transposed elsewhere in the viral genome. The induction of a sufficiently long stretch of DNase I-sensitive chromatin leads to the appearance of a visible nucleosome-free region.

LATE in infection, simian virus 40 (SV40) DNA is found in the nucleus of infected cells in the form of a minichromosome (see ref. 1 for references). When nuclei of SV40-infected cells or isolated SV40 minichromosomes are treated with various endonucleases (refs 2–4 and references therein) a region extending for ~350 base pairs (bp) from the unique *Bgl*I site towards the late side is preferentially cut (the ori region; Fig. 1, ORI A). Detailed studies of the products of DNase I digestion early and late in infection have revealed the existence of several discrete hypersensitive sites within this DNA fragment[5,6] and electron microscopy has shown that ~25% of the minichromosomes extracted from nuclei late in infection contain a nucleosome-free region (the nucleosome gap) of ~350 bp located in the same position[3,7]. Studies with viral mutants in which parts of the ori region are duplicated indicate that this region contains the information required for the generation of the nuclease-

0028-0836/84/080708—07$01.00

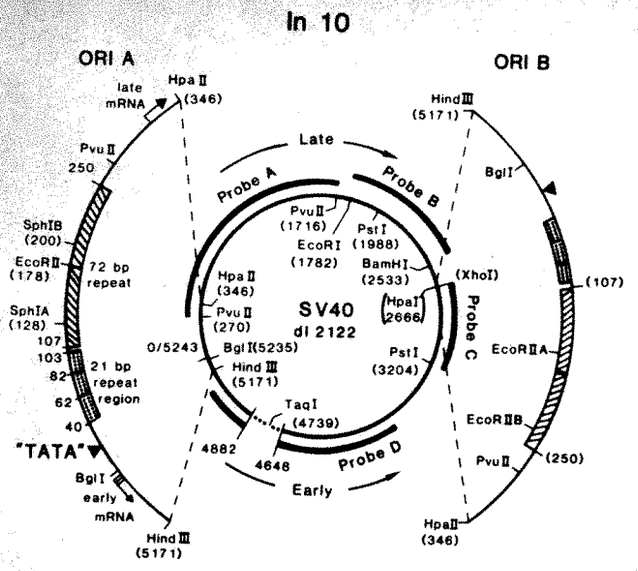

Fig. 1 Schematic representation and construction of the SV40 mutant In10. The inner circle represents the genome of SV40 d12122 which has a 234-bp deletion around the *Taq*I site (dotted line). The position and coordinates of some relevant restriction sites and landmarks are indicated and numbered according to the BBB system[1]. The SV40 ori region (ORI A) which contains the origin of replication (around the *Bgl*I site) and the early and late gene promoter sequences are shown enlarged at the left-hand side. The three early gene promoter elements (TATA box, 21-bp repeat region and 72-bp repeat) are indicated. A similar ori region from *Hin*dIII to *Hpa*II (5,171–346) was inserted at position 2,666 in the same orientation with respect to early gene transcription, as shown enlarged on the right-hand side (ori B). The ori fragment was taken from plasmid pSV1 and contained an 8-bp deletion from position 173 to 181, deleting the *Eco*RII site at position 178 (ref. 12). The solid bars indicate the restriction fragments used as hybridization probes to map regions of increased DNase I sensitivity at ori A and ori B. To generate the SV40 insertion mutant In10, the following plasmids were first constructed: pSV22, a recombinant between the DNA of SV40 d12122 and a *Pst*I site-deleted pBR322 joined at their unique *Eco*RI sites; pSV10, the small SV40 *Pst*I fragment (1,988–3,204) was inserted in the *Pst*I site of pBR322; pSV10IN10, constructed by blunt-end ligation (after DNA polymerase I treatment) of the *Hin*dIII–*Hpa*II ORI fragment (5,171–346) in the unique *Hpa*I site present in the SV40 *Pst*I fragment of pSV10. The small *Pst*I fragment of pSV10IN10 was purified on a sucrose gradient and ligated in pSV22 in place of the original SV40 *Pst*I fragment to give pIN10. Virus stocks of SV40 d12122 and In10 were prepared from pSV22 and pIN10 as follows: DNA from plasmids pSV22 and pIN10 was digested with *Eco*RI to separate the SV40 moiety from the pBR322 sequences, ligated at low DNA concentrations (5–10 $\mu g\ ml^{-1}$) to circularize the DNA, and transfected into CV-1 cells in the presence of 0.5 $mg\ ml^{-1}$ DEAE-dextran[12] using 50 ng of ligated DNA per 6 cm Petri dish. Virus was collected by repeated freezing and thawing when 90% of the cells had lysed. Virus stocks were then prepared by infections at low multiplicity with plaque-purified virus and used for subsequent experiments. Recombinant constructions were verified in plasmids by partial DNA sequencing and in virus stocks by detailed restriction analysis of Hirt extracts.

sensitive chromatin structure[8,9] and the nucleosome gap[8,10].

These findings are of particular interest because the ori region contains the DNA sequences involved in initiation of transcription of early and late SV40 genes (see ref. 1) in addition to the viral replication origin[11]. Recent studies have defined three DNA regions which have a role in promotion of early gene transcription *in vivo*. These are (Fig. 1) the 'TATA box', which dictates the proper initiation site for transcription[12–14], the 21-bp repeat region containing six G+C-rich repeated sequence motifs, the deletion of which decreases early gene expression[12,15,16], and the enhancer element, the 72-bp repeat. Deletion of one of the two 72-bp sequences has very little effect on early gene expression but deletion of all, or part, of the remaining repeated sequences reduces early transcription considerably[12,14,17–21].

Therefore, the early promoter sequences are localized within the same fragment of the SV40 genome that displays an altered chromatin structure. Similarly, a variety of cellular genes show alterations in chromatin structure upstream from the mRNA cap site, which correlate with transcriptional activity (refs 22–25 and references therein). Thus, alterations in chromatin structure, as detected by increased sensitivity to endonucleases and the presence of a nucleosome gap, might be induced by transcriptional promoter elements.

Here we describe experiments which were designed to identify the sequences in the ori region necessary to induce chromatin structures of increased DNase I sensitivity and a nucleosome gap. Our approach was based on the observation that SV40 mutants having deletions in the large-T intron can accommodate extra DNA sequences in the *Hpa*I site at position 2,666 (Fig. 1) and still grow normally[26]. Different parts of the ori region were inserted at this *Hpa*I site using the mutant d12122, which has a deletion between positions 4,648 and 4,882 (ref. 27) to create mutants carrying two ori regions: the wild type ori A, and a second wild type or mutated origin region, ori B (Fig. 1).

Induction of DNase I sensitivity

Figure 1 describes the double-origin mutant In10 which has the 418-bp *Hin*dIII–*Hpa*II ori fragment (5,171–346; Fig. 1) inserted as a second ori (ori B). To measure the increased DNase I sensitivity at ori A and B, CV-1 cells were infected with an In10 virus stock, nuclei were prepared 40–42 h later, and regions of increased DNase I sensitivity were mapped using an indirect end-labelling technique[28]. The pattern of DNase I digestion at ori A and B was revealed after hydridization of the blotted DNA to probes A and B, respectively (see Fig. 1 and Fig. 2 legend).

An example of a resulting autoradiogram using probe A is shown in Fig. 2*a* (ORI A). The heavy band (L) corresponds to In10 DNA which was not digested with DNase I, but only linearized with *Eco*RI. In10 chromatin DNA digested randomly with DNase I gave rise to a continuous smear, the intensity of which increased with increasing time of DNase I digestion. Regions of increased DNase I sensitivity at ori A produced two sets of DNA fragments, labelled I and II. DNA purified from In10-infected cells (or from cells infected with other In mutants described in this study) and digested with DNase I and *Eco*RI showed only the background smear (not shown). The early border of the DNase I-sensitive region II mapped at position 109 ± 25 and thus coincided well with the early border of the 72-bp repeat (Fig. 2*c*). The late border of region II mapped at position 323 ± 20. Occasionally, rather than a continuous smear, region II in ori A was resolved into two or three separate sets of fragments of unequal intensity, suggesting the existence of several subregions. The most prominent subregion (arrow in Fig. 2*a*) was always proximal to the early side of region II. Figure 2*a* also shows that using probe A, the DNase I-sensitive region I was ~30 bp long and centred over position 5,220. However, the presence of the highly DNaseI-sensitive region II between region I and the *Eco*RI site used as a reference point for the mapping experiments, might have led to an underestimation of the length and intensity of region I. When the *Mbo*I site at position 4,099 was used as a reference point using a *Mbo*I–*Ava*II fragment (4,099–5,118) as probe (probe D, Fig. 1) region I was shown to include the TATA box and extended from position 5,210 to 35. The pattern of DNase I sensitivity determined over ori A in In10 was similar to that found in wild-type SV40, d12122 and all double-origin mutants tested (results summarized in Fig. 2*c*, 'ORI A'). Similar results were reported by Saragosti *et al.*[3] for wild-type SV40.

Figure 2*a* (ORI B) shows that when probe B was used instead of probe A, a pattern of DNase I sensitivity similar to that seen at ori A was revealed at ori B. Region II at ori B mapped from position 110 ± 25 to 310 ± 20, while region I mapped from position $5{,}220 \pm 20$ to 45 ± 20 (Fig. 2*c*). These locations were

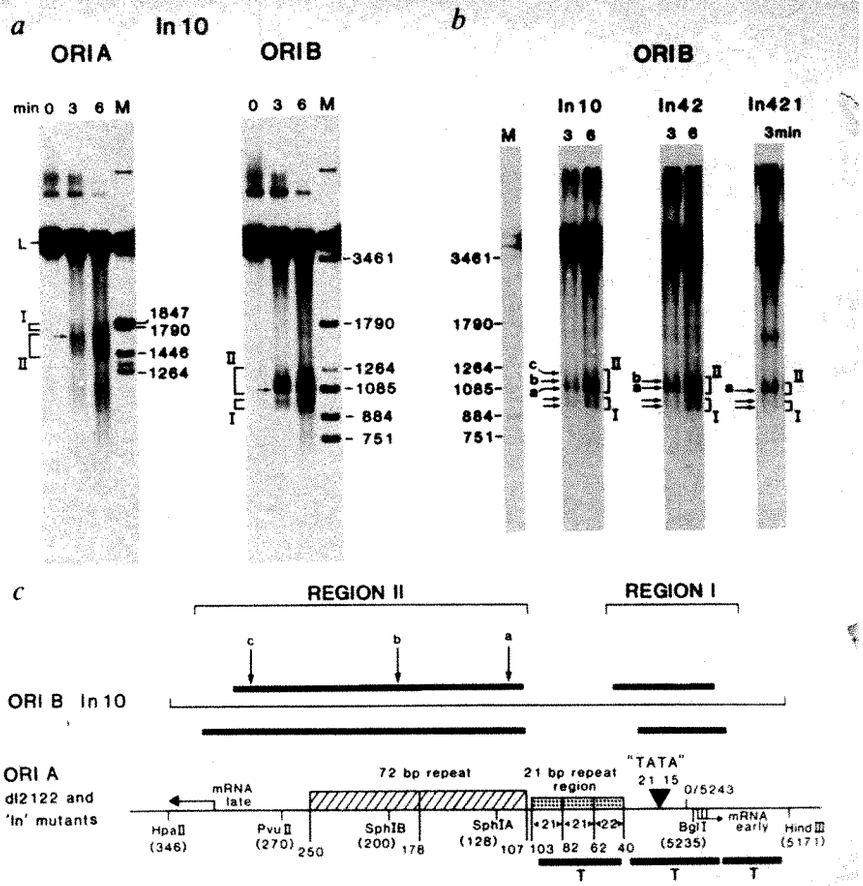

Fig. 2 Mapping of the regions of increased DNase I sensitivity at ori A and ori B of In10, In42 and In421. ***a***, Mapping of DNase I-sensitive regions at ori A and ori B was done as follows. CV-1 cells were infected with the appropriate virus stock and collected 40–42 h after infection by scraping them into a small volume of ice-cold buffer A (75 mM KCl, 5 mM PIPES *p*H 7.0, 150 mM sucrose) containing 1 mM EDTA, then washed twice with the same buffer by centrifugation for 5 min at 3,000 r.p.m. in a Sorvall HB-4 rotor at 4 °C. The cells were lysed in buffer A containing 0.5% Nonidet P-40 for 5 min on ice and the nuclei were washed once with buffer A by centrifugation as described above. The nuclear pellet was resuspended in buffer A at a DNA concentration of 0.5–1.0 mg ml^{-1}. Nuclease digestions were carried out at room temperature by adding 0.1 vol. 10 mM $CaCl_2$ and DNase I (Worthington; 2,624 U mg^{-1}) to a final concentration of 120 U ml^{-1} in a total volume of 550 μl. Samples (90 μl) were removed at various times and immediately mixed with 110 μl of 20 mM Tris-HCl *p*H 7.4, 10 mM EDTA, 0.2% SDS, containing 20 μg proteinase-K and incubated at 37 °C for 2–3 h. The samples were extracted once with 1 vol. phenol–chloroform (1:1) and once with 3 vol. ether. The aqueous phase was digested with RNase A at 10 μg ml^{-1} for 1 h at 37 °C and extracted with phenol–chloroform and ether, then the DNA was digested with a twofold excess of *Eco*RI (BRL) and layered onto a 2% agarose gel for electrophoresis. DNA was transferred from the agarose gel to a nitrocellulose filter and hybridized according to Wahl *et al.*[42], but with omission of the dextran sulphate. To map the regions of increased DNase I sensitivity at ori B, the filter was hybridized to probe B (Fig. 1) labelled with ^{32}P by nick-translation. After dehybridization at 65 °C for 2 h as described by Thomas[43], regions of increased DNase I sensitivity at ori A were mapped using probe A (Fig. 1). The time of digestion with DNase I is indicated (in min) at the top of each lane. Lane M contains marker fragments prepared by digesting SV40 DNA with the restriction enzymes: *Eco*RI + *Bgl*I, *Eco*RI + *Bam*HI, *Pvu*II, *Hin*fI and *Mbo*I. Lane M contains 50 ng of each digest and the numbers to the right of each panel represent the length (in bp) of the restriction fragments detected by the hybridizing probe. The 884-bp marker fragment visualized by probe B (in ORI B) is the *Eco*RI–*Hpa*I fragment (1,782–2,666), which marks the extremity of the inserted fragment proximal to probe B. The DNase I-sensitive regions I and II described in the text are indicated by brackets and a prominent band visible in region II at ori A and ori B is indicated by an arrow. L, linearized viral DNA. In the particular experiment shown here dehybridization was incomplete; this resulted in the appearance of a signal corresponding to ORI B in the panel labelled ORI A below the 1,264-bp marker fragment. ***b***, Fine structure in region II at ori B. Samples of In10, In42 and In421 were standardized as described in the text to allow a valid comparison of the DNase I digests. The 3-min digestion points of the three mutants were digested to the same degree at ORI A. Similarly, the 6-min time points for In10 and In42 were directly comparable. The extent of the DNase I-sensitive regions is indicated by brackets labelled I and II and arrows indicate the fine structure within these regions. Lane M contains marker fragments as for ***a***. The construction of pIN42 and pIN421 is described in Fig. 5 legend. ***c***, Diagrammatic comparison of regions of increased DNase I sensitivity at ori B in In10 and ori A in wild-type and mutant SV40. The lower line (ori A) represents the SV40 ori region with the TATA box, the 21-bp repeat region and the 72-bp repeat. The three solid bars below the line indicate the three T-antigen-binding sites[32,33]. The solid bars above the lines ori A and ori B In10 indicate the extent of regions of increased DNase I sensitivity I and II, and are a summary of several mapping experiments using probes A and D to analyse ori A, and probes B and C to analyse ori B. The vertical arrows indicate the approximate location of the bands a, b and c shown in *b*.

confirmed using probe C and the *Pst*I site (3,204; Fig. 1) as a reference point (not shown). Several similarities in the digestion patterns at ori A and ori B in In10 are noteworthy. First, both regions of DNase I sensitivity at ori B mapped over the same DNA sequences as at ori A. Second, region II at ori B was more sensitive to digestion with DNase I than region I; this confirmed that the increased DNase I sensitivity of region II compared with region I at ori A (see above), was not due to the use of a probe from the late side which might have led to a preferential mapping of DNase I cut sites proximal to the *Eco*RI site. Third, region II at ori B also showed a fine structure with a prominent band mapping close to the early side of the 72-bp repeat (arrow in Fig. 2*a*, ORI B). Figure 2*b* gives the results of an experiment showing more clearly the presence of five bands at ori B in In10 (arrows), two of which mapped within region I and three within region II.

To investigate which sequences were responsible for the induction of region II and the prominent cuts contained within it, we constructed mutants In42 and In421, which contain *Hin*dIII–*Pvu*II ori fragments (5,171–270) with an intact 72-bp repeat or only one 72-bp sequence, respectively (Fig. 5*a*). To validly compare the DNase I digestion patterns at ori B for the different mutants, we first ensured that all samples were equilibrated for viral yield and degree of digestion. To this end, different amounts of total DNA extracted from infected cells were loaded on the gel and then only those samples which showed identical signals for the linear SV40 DNA (band L in Fig. 2*a*) and an equal degree of digestion at ori A as determined by hybridization with probe A, were compared at ori B using probe B (the same standardization procedure was used for all the experiments described below). The absence of the *Pvu*II–*Hpa*II fragment (270–346) at ori B in In42 resulted in the appearance of a shorter region II lacking band c (Fig. 2*b*). Additional deletion of one 72-bp sequence (In421) shortened region II even further and eliminated band b (Figs 2*b*, 5*a*). From these results, together with the data of several mapping experiments, we conclude that bands a and b fall on the early side of each 72-bp sequence and band c on the late side of the

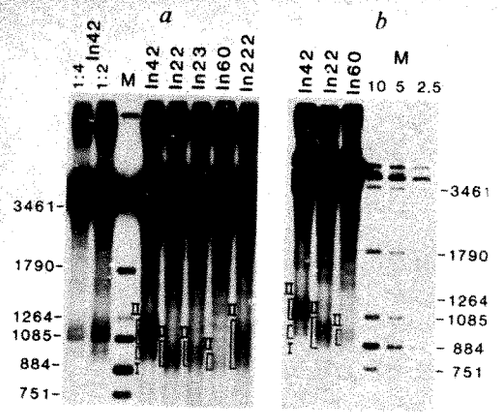

Fig. 3 The 72-bp repeat induces an altered chromatin structure over itself. *a*, The DNase I digestion patterns at ori B of different In mutants as indicated at the top of each lane, were visualized using probe B (see Fig. 1) and the extent of regions of increased DNase I sensitivity are indicated by brackets. Samples were standardized as described in the text. To estimate the magnitude of the differences in intensity of region II in In42, In22 and In23, twofold and fourfold dilutions of the In42 sample shown in the central panel were included (In42 diluted 1:2 and 1:4). Lane M contains markers as described for Fig. 2*a*. The samples were digested at ori A to ~5% (as determined by the ratio of the signals corresponding to linear SV40 and to DNase I cuts at ori A). *b*, A different set of standardized samples digested at ori A to ~25% was run on a separate gel in the presence of different amounts of marker fragments (lanes M containing 10, 5 or 2.5 μl of the same marker mix). The construction of the In mutants is described in Fig. 5 legend.

*Pvu*II (270) restriction site. In all three mutants In10, In42 and In421, region II was of equal intensity and was always more sensitive than region I.

The relationship between bands a, b and c and the specific cuts made at the wild-type SV40 ori region at positions 370, 270 and 190 as reported by Cremisi[5] is unclear, but the differences in position may be related to the use of rather long fragments starting from the *Eco*RI site to probe the structure of the ori region. The use of shorter probes localized nearer to the ori region of wild-type SV40 has allowed the identification of as many as five specific cuts within region II[6], three of which were mapped at positions 110, 185 and 290 and thus may correspond to the bands a, b and c described here. The two additional cuts which were mapped by Cereghini *et al.*[6] within the 'late' moiety of each 72-bp sequence probably reflect the higher degree of resolution obtained in their assay. As specific bands within regions of increased DNase I sensitivity result from the cuts made at hypersensitive sites at an early stage of DNase I digestion, it is possible that the exact number and location of such cuts differ with experimental conditions and may depend on various parameters such as temperature, digestion buffer, amount of DNase I or method of preparation of nuclei.

Induction of DNase I sensitivity by enhancer

To further define the sequences necessary to induce the increased DNase I sensitivity over region II, we inserted in both orientations at ori B a DNA fragment from position 113 to 270, containing mainly the 72-bp repeat (In22 and In23; Fig. 5*a*). Both mutants displayed a DNase I-sensitive region of similar intensity over the inserted fragment (see Fig. 3*a*, region II). This sensitive region differed from the region II in In42 in several ways. First, regions II in In22 and In23 seemed to be less intense than region II in In42. To estimate the magnitude of this difference, several dilutions of the In42 sample were included on the same gel. From a comparison of these samples, we estimated the intensity of regions II in In22 and In23 to be 2–3-fold less than in In42 (Fig. 3*a*, In42 diluted 1:2 and 1:4). Second, regions II in In22 and In23 appeared more diffuse, and third, although some fine structure was visible in region II in In22 and In23, no prominent band close to the early border of the inserted 72-bp repeat was observed. The decreased DNase I sensitivity of the isolated 72-bp repeat at ori B in In22 and In23 (compared with region II at ori B in In42) could be due to the absence of certain ori sequences on the early side of this repeat or could be related in some way to the smaller size of the insert. To test the effect of the size of the insert, we took advantage of a uniquely reconstructed *Xho*I site at one end of ori B in In22 to insert a second 72-bp repeat (from position 113 to 270), thus constructing In222 carrying an insert of approximately the same length as In42 (Fig. 5*a*). Figure 3*a* shows that a duplication of the DNase I-sensitive region seen in In22 was present at ori B of In222, but of the same intensity as in In22 or In23. This suggested that sequences between the *Hin*dIII site (5,171) and position 113 affected the intensity of the DNase I sensitivity generated over the 72-bp repeat.

We also tested whether a single 72-bp sequence was able to induce an altered chromatin structure by deleting one of the two 72-bp sequences from ori B of In22 (In60, Fig. 5*a*). The remaining region of increased DNase I sensitivity at ori B was shorter than in In22 or In23 and also seemed less intense (Fig. 3*a*). To ensure that these differences in intensity were not due to different digestion kinetics, we prepared another set of standardized samples from In42, In22 and In60 (Fig. 3*b*) which were more heavily digested with DNase I than the set shown in Fig. 3*a*. Using the marker lanes as standards, we again estimated that region II in In22 was 2–3-fold less intense than in In42 and that the DNase I sensitivity induced at ori B in In60 by a single 72-bp sequence was reduced ~2–3-fold compared with the intact 72-bp repeat (In22) or a dimer of this repeat (In222). This latter decrease might be due to the small size of the insert in In60 rather than be related to the deletion of specific sequences. Also, note that the insert at ori B in In60 consists of slightly less than an intact 72-bp sequence since its early border is at position 113.

Two reports which appeared when this work was in progress have dealt with the effects of the 72-bp repeat on chromatin structure using SV40 mutants containing transposed ori fragments. Gerard *et al.*[9] concluded that this repeat was not in itself sufficient for the induction of increased nuclease sensitivity. These authors used an ori fragment containing a single 72-bp sequence and might, therefore, have been unable to detect the increase in nuclease sensitivity induced by this fragment (compare In22 and In60, Fig. 3*a*, *b*). The results given in Fig. 3*a* clearly demonstrate that the 72-bp repeat induces an increase in DNase I sensitivity independent of its orientation (In22 and In23). This is in contrast to the findings of Fromm and Berg[29] who inserted an ori fragment (from position 95 to 270) into the *Hpa*I site (2,666) of a SV40 genome in which a fragment from position 73 to 270 had been deleted from the wild-type ori region. They found that the 95–270 fragment induced an increase in DNase I sensitivity only when inserted in the orientation comparable to ori B in In23. This discrepancy could be due to the small difference in the sequences of the ori fragments tested in the two studies (base pairs 113 to 270 in our study) or to other differences in the recombinant constructions.

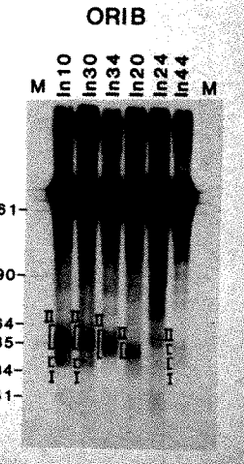

Fig. 4 Determination of the ori sequences needed to induce DNase I-sensitive region I. Samples were standardized as described in the text and the pattern of DNase I digestion was visualized as described in Fig. 3 legend. Extent of regions I and II are indicated by brackets. In24 was digested slightly more than the other samples to ensure that no region of increased DNase I sensitivity was present at ori B. Lanes M contain markers as in Fig. 2*a*. The construction of In mutants other than In10 is described in Fig. 5 legend.

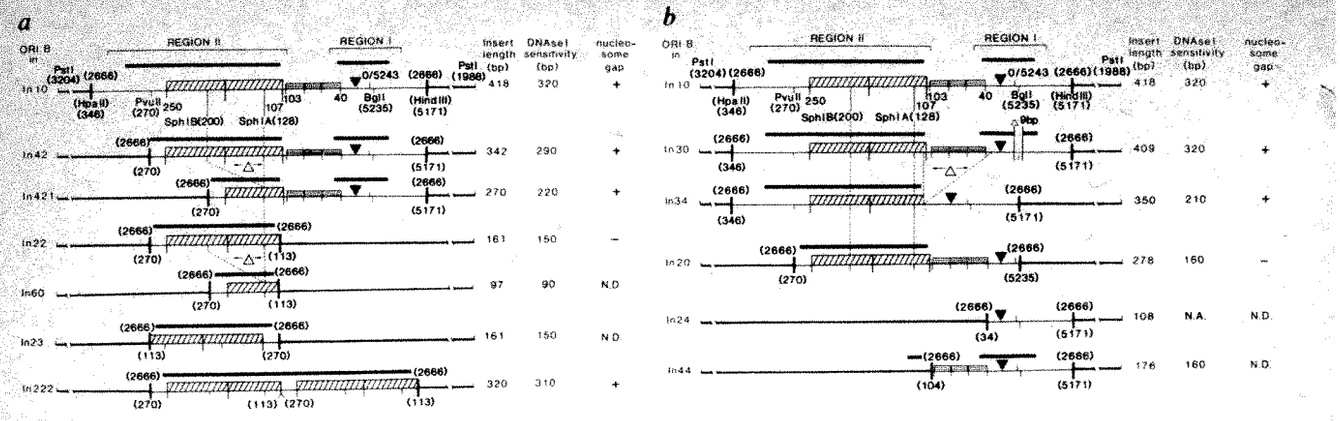

Fig. 5 Diagrammatic representation of the results obtained with the various In mutants. The small *Pst*I fragments containing ori B are shown (see Fig. 1). For each mutant the insert at ori B is represented by a thin horizontal line bounded by thick vertical bars. The extent of the regions of increased DNase I sensitivity (I and II) are indicated by black horizontal bars as in Fig. 2*c*. The column 'DNase I sensitivity' gives the distance (in bp) between the outer extremities of the domain of DNase I-sensitive chromatin. Approximately 25% of the minichromosomes extracted from cells infected with any of the In mutants exhibited at least one nucleosome gap. More than 150 minichromosomes containing at least one gap of those mutants for which + appears in the right-hand columns of *a* and *b* were examined to determine the percentages of minichromosomes exhibiting two gaps—these were as follows: for In10, 32%; In34, 30%; In30, 27%; In42, 22%; In421, 28% and for In222, 24%. When no minichromosomes containing two gaps were seen (indicated by −) more than 300 minichromosomes containing a single gap were examined. N.A., not applicable; N.D., not determined. ***a***, Summary of results defining ori sequences needed to induce region II. In42, In22 and In23 were constructed by directly inserting the appropriate ori fragments in pSV22X, a derivative of pSV22 (see Fig. 1 legend) in which the *Hpa*I site at position 2,666 was converted to a unique *Xho*I restriction site by inserting a *Xho*I linker. In421 was derived from In42 by deletion of one 72-bp sequence between *Sph*I A and *Sph*I B at ori B. The insert in In22 is the pHS102 fragment A (113–270) described by Moreau *et al.*[17]; the same insert is present at ori B in In23 in the opposite orientation. In60 is derived from In22 by deletion of the *Sph*I A–*Sph*I B fragment at ori B. In222 was constructed by inserting a second 72-bp repeat (113–270) in the *Xho*I site reconstituted at the 'late' side of ori B in In22. ***b***, Summary of results defining ori sequences necessary to induce region I. In20 was constructed in a way similar to In10 (as described in Fig. 1 legend) using a purified *Bgl*I–*Pvu*II fragment (5,235–270) derived from pSV1. The other In mutants were constructed as described above for In42 using the following ori fragments: the *Hin*dIII–*Hpa*II fragment (5,171–346) from pAS[12] which has a 9-bp deletion around the *Bgl*I site (In30) or from pMD102[15] which has a deletion between positions 34 and 113 (In34), or the *Hin*dIII–*Bam*HI fragments from pRE7 (5,171–34; In24) or from pMKD231 (5,171–104; In44) described by Everett *et al.*[15].

Importance of 21-bp repeat region

As DNase I-sensitive region I maps over the origin of replication proper[11], we investigated whether an intact replication origin at ori B was necessary for the generation of region I. ori B in In30 is similar to ori B in In10 (Fig. 1) but has a 9-bp deletion around the *Bgl*I site (see Fig. 5*b*), which is known to abolish SV40 replication[30]. Although this deletion had no effect on the induction of DNase I-sensitive region I or II (Figs 4, 5*b*), insertion at ori B of the *Bgl*I–*Pvu*II fragment (5,235–270), which lacks the early moiety of the sequences contained within region I (In20; Fig. 5*b*) but not the TATA box, did not generate a stretch of increased DNase I sensitivity corresponding to region I (Fig. 4). Comparing these results with those obtained using In42 (carrying the *Hin*dIII–*Pvu*II fragment at ori B; see Figs 2*b*, 5*a*) indicated that the generation of region I required the presence of sequences between the *Hin*dIII and *Bgl*I sites. In addition, the insert at ori B of In20 induced a region II which mapped from position 110 ± 10 to 265 ± 15 (Figs 4, 5*b*), thus confirming the above conclusion that sequences between *Pvu*II (270) and *Hpa*II (346) are important in defining the late border of region II.

To determine whether, as in the case of region II, the sequences within region I were able to induce DNase I sensitivity over themselves, we constructed In24 which carried at ori B the fragment from position 5,171 to 34 and contained essentially all the DNA sequences included in region I (In24; Fig. 5*b*). No increase in DNase I sensitivity was induced over this insert (Fig. 4). When we tested In44, which contained at ori B a fragment spanning positions 5,171 to 104, encompassing as in In24 all sequences contained within region I plus the 21-bp repeat region, we observed two regions of increased DNase I sensitivity (In44; Figs 4, 5*b*), one region mapped from position 5,230 ± 10 to 60 ± 10 and was therefore similar to region I at ori A, while a second narrow region mapped just outside the insert on its 'late' side. Both regions of increased DNase I sensitivity at ori B in In44 were of lower but equal intensity (Fig. 4), compared with the characteristic wild-type pattern at ori A in In44 or at ori B in In10, In30, In42 or In421. These results suggested that DNA sequences localized between positions 34 and 104 (that is, the 21-bp repeat region) were responsible for the induction of region I over the ori sequences located directly on its early side, and might also influence the pattern of increased DNase I sensitivity over the 72-bp repeat which in the wild-type ori is located directly on its late side. Both suggestions were confirmed by the results obtained at ori B in In34, which was similar to In10 but lacked the 21-bp repeat region (Fig. 5*b*). Not only was region I absent at ori B in In34, but inspection of several autoradiograms similar to that shown in Fig. 4 revealed also that band b of region II in In34 was more intense than band a, in contrast to the relative intensity of these bands in region II of In10 (Fig. 2*b*).

Induction of a nucleosome gap

About 25% of wild-type SV40 minichromosomes extracted from nuclei late in infection contain a nucleosome gap over their ori region. To investigate whether this gap could be observed at ori B, minichromosomes were extracted from CV-1 cells 40–42 h after infection with an In10 virus stock. Approximately one-quarter of the minichromosomes had a nucleosome gap (Fig. 6*a*) which appeared to map preferentially over ori A when using the single-cut restriction enzymes *Eco*RI (Fig. 6*b*) or *Msp*I (Fig. 6*c*). (Note that the *Hpa*II–*Msp*I site was lost at ori B.) In addition, two diametrically opposed gaps were observed in approximately 7% of the minichromosomes (Fig. 6*d*). These two gaps were mapped over ori A and ori B after digestion with *Eco*RI (Fig. 6*e*) or *Msp*I (Fig. 6*f*). To determine which ori sequences were responsible for the generation of the gap, we analysed most of the 'In' mutants described above for the presence of a gap at ori B. The results, summarized in Fig. 5*a*,*b* indicate that a similar fraction of the minichromosomes of the two mutants In 42 and In421 exhibited two gaps, mapping over ori A and ori B, while mutants In20 and In22 exhibited a gap only over ori A. The absence of a visible gap over ori B in In20

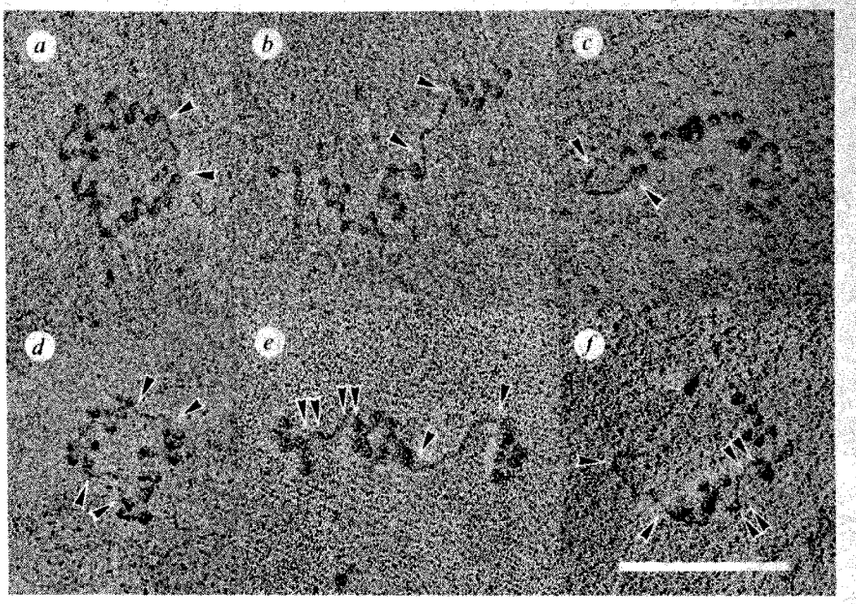

Fig. 6 Electron microscopic visualization of In10 minichromosome. Minichromosomes were extracted and purified from CV-1 cells 40–42 h after infection as described elsewhere[44]. Aliquots from the 75S peak fraction were digested with *Eco*RI (*b* and *e*) or *Msp*I (an isoschizomer of *Hpa*II; *c* and *f*) after addition of $MgCl_2$ to a final concentration of 5 mM. The digestion was stopped by adding 5 mM EDTA. Undigested minichromosomes (*a* and *d*) and the digested samples were diluted at least 10-fold in water and 10-μl aliquots were deposited on carbon-coated grids which had been positively charged by glow discharge in the presence of amylamine. After 1 min of adsorption, the grids were rinsed for 5 min with water then stained for 10 s in 0.1% aqueous uranyl acetate. The grids were then washed for 5 s with water, air-dried and shadowed as described previously[44]. Scale bar in *f* represents 0.25 μm. The positions of nucleosome gaps were mapped on minichromosomes cut with a restriction enzyme by counting the nucleosomes between the gap and the extremities of the linearized molecules. *a*, *b*, *c* Show minichromosomes containing one nucleosome gap which mapped over ori A. *d*, *e*, *f* Show minichromosomes containing two gaps. In *e* and *f* the gaps indicated by single arrowheads map over ori A and the gaps indicated by double arrowheads map over ori B.

was not due to the smaller size of the inserted fragment, as the insert at ori B in In421 was of a similar size. A possible means of accounting for these results is to postulate that the presence of DNase I-sensitive region I was a prerequisite for the observation of a gap. However, when we examined minichromosomes from In34 which showed no region I at ori B, we found a gap over ori B (Fig. 5*b*). Alternatively, the induction of a visible nucleosome gap might require the existence of a minimal length of altered chromatin structure which could be made up of either a complete region II as in In34 or a truncated region II plus an adjacent region I as in In42 or In421. To test this hypothesis, we examined minichromosomes extracted from In222-infected cells and found that a fraction of them contained two gaps (Fig. 5*a*). These results strongly support the conclusion that the total length of increased DNase I sensitivity at ori B is the crucial factor in allowing gap formation, and that the nuclease-sensitive structure and the nucleosome gap occur on the same minichromosomes. In fact, we have recently determined that the visible gap region of isolated wild-type minichromosomes is preferentially excised with *Bgl*I and *Msp*I restriction enzymes (E. Weiss *et al.*, in preparation).

Discussion

Our experiments, reported here, demonstrate that generation of the full pattern of increased DNase I sensitivity at the SV40 ori region depends on the presence of multiple ori sequences and on their precise arrangement. First, the generation of a full-length region II depends on both sequences within the 72-bp repeat and a separate set of sequences located between the *Pvu*II (270) and *Hpa*II (346) sites (compare In10, In42 and In44). Second, region I is induced only when the 21-bp region, which is itself resistant to DNase I digestion, is present together with sequences between the *Hin*dIII (5,171) and *Bgl*I (5,235) sites (compare In10, In34 and In20). Third, the 21-bp repeat region has a distinct qualitative effect on the generation of increased DNase I sensitivity over the 72-bp repeat, leading to a well defined 'early' border and a prominent subregion (band a; compare In10 and In34). Studies using mutated 21-bp repeat regions are required to investigate whether the effects of this region on chromatin structure are related to its promoter activity for early[12,14–16] or late[19] genes and whether its resistance to DNase I digestion is due to the binding of a transcription factor[31] or of T-antigen[32,33]. In any case, a large fraction of the increased DNase I sensitivity at ori is critically dependent on the presence of the 72-bp repeat (compare In10, In42, In421 and In44). Most important, an alteration of chromatin structure is generated at ori B by insertion, in either orientation, of the 72-bp repeat region, in the absence of other ori sequences (In22 and In23).

Our results also indicate that the formation of a visible nucleosome gap is correlated with the generation of a sufficiently long stretch of altered chromatin structure, the minimal length of which seems to be between 160 and 210 bp (see Fig. 5*a*,*b*). This can be achieved in various ways, but the major conclusion is that sequences mostly contained within the 72-bp repeat are sufficient to generate a visible nucleosome gap (see In222). It is possible that a single 72-bp repeat could generate a nucleosome gap which is not detectable because its length is too close to the maximal size of the variable internucleosomal linker length of spread SV40 minichromosomes[1,3].

The SV40 72-bp repeat has been characterized as a *cis*-acting bidirectional enhancer of transcription from potential promoter elements[21]. The observations that proximal potential promoter elements are preferentially activated and that activation of transcription from a given promoter element decreases as the length of interposed sequences increses, have suggested that the SV40 enhancer acts like a bidirectional 'entry site' for some element(s) of the class B transcription machinery[17,21]. Our present results suggest that the generation of an altered chromatin structure by the SV40 enhancer could lead to the formation of an 'open window' within the nucleosomal structure, thereby increasing the accessibility of the DNA within the enhancer for binding of macromolecules involved in transcription. Of course, this does not exclude the possibility that sequences within the 72-bp repeat could be specifically recognized by some component of the transcription machinery, as was recently suggested by the stimulatory effect of the 72-bp repeat on *in vitro* transcription from heterologous promoter elements in the absence of evidence for chromatin reconstruction[34]. One could speculate that the generation of an open chromatin structure and sequence-specific interaction between the 72-bp repeat and the transcription machinery act in concert to facilitate the activation of promoter elements embedded in the complex genome of higher eukaryotes.

The molecular mechanisms underlying the generation of altered chromatin structures over the 72-bp repeat are unknown. Several possibilities exist. *In vitro* reconstitution experiments showing that nucleosomes form less well on the ori region than on the rest of the SV40 genome suggest that some DNA sequences within the ori region cannot easily be folded around the histone octamer core[35,36]. We note that it has been demonstrated recently that some sequences within and on the late side

of the 72-bp repeat can exist in the Z-DNA conformation *in vitro*[37] and that nucleosomes cannot be formed over Z-DNA[38]. The alterations in chromatin structure may also be brought about by the binding of specific proteins, thereby inhibiting nucleosome formation. Interactions between enhancer sequences and specific cellular proteins have been suggested recently by studies demonstrating that the activity of some viral and cellular enhancers is cell- and/or species-specific (refs 39, 40 and references therein). Such proteins could be component(s) of the transcription machinery (see above) or belong to the class of proteins which specifically recognize Z-DNA[41]. Obviously, the identification of such putative proteins, the further development of *in vitro* systems, and the precise characterization of the sequences within the 72-bp repeat responsible for the enhancing activity and the generation of altered chromatin structures, are required to elucidate the molecular mechanisms underlying these important biological functions.

We thank Drs R. Everett and E. May for gifts of materials; K. Dott, M. Acker, B. Augsburger and E. Regnier for technical assistance; and C. Werlé, B. Boulay, E. Badzinski and C. Kutschis for help in preparing the manuscript. This work was supported by grants from the CNRS (ATP 3582), the INSERM (PRC 124026), the Ministère de la Recherche et de l'Industrie (82V1283), the Association pour le Développment de la Recherche sur le Cancer, the Fondation Médicale de la Recherche Française, and the Fondation Simone and Cino del Duca. J.J. was the recipient of a long-term EMBO fellowship and T.L.R. was supported by a fellowship from the University Louis Pasteur, Strasbourg. A new mine determination of the newtonian gravitational constant

S. C. Holding & G. J. Tuck

Physics Department, University of Queensland, Brisbane 4067, Australia

Recent theoretical interest in the possibility of observing a non-newtonian component of gravity arises from the lead that such observations will give to unification theories[1]. Absolute determinations of the newtonian constant *G* by geophysical methods, at mass separations several orders of magnitude greater than those available in the laboratory, provide information not obtainable in any other way. Stacey[2] drew attention to the fact that modern geophysical measurements were precise enough in principle to provide an important check on *G* and Stacey *et al.*[3] revived the mine method first used by G. B. Airy. Subsequently Stacey analysed a set of overlapping sea-floor and sea-surface gravity survey data made available by the Exxon Oil Co., to avoid the problem of density uncertainty that beset the mine measurements, and Stacey and Tuck[4] compared the results with values of *G* calculated from published mine and borehole data. The striking conclusion was that the values of *G* were all systematically high. Residual doubts, especially concerning the adequacy of density sampling and the possibility of bias by regional gravity anomalies, left the conclusion as a rather tentative one. We report here a new determination of *G*, which is also high, but in which the doubt about density is substantially reduced. This information makes it implausible to explain the high value of *G* in terms of an inadequate knowledge of density. The possible effect of regional gravity anomalies is not as securely discounted.

The measurements were made in the Hilton mine (24°34′ S, 139°28′ E), operated by Mount Isa Mines Ltd. We have made full use of the company's file of density data, from extensive coring of the area, and knowledge of geological structure by company staff. Over 2,300 core sample densities were used to establish the density pattern of the region. Gravity values were obtained at the surface and at 11 subsurface levels down to 993 m in stubs to one side of the P49 shaft (Fig. 1), using La Coste-Romberg meter G608. This was checked against the well calibrated G20 meter used previously and procedures for checking instrument drift, applying tidal corrections and so on, were the same as in the previously reported survey[3]. Data from the J53 shaft are not considered here as the density inhomogeneity immediately surrounding J53 and the shorter vertical extent of the shaft combine to give a much less accurate value of *G*. The equations for calculating *G* from the gravity profile and layer densities are given by Stacey *et al.*[3] (and confirmed by Dahlen[5]), but a slight variation was required in the present case to take full account of the documented inhomogeneities.

The method used by Stacey *et al.*[3] was to average all density values at depths between gravity stations to obtain mean layer densities between those levels. Our method was first to assume a regional average density (2,750 kg m^{-3}) and then to correct the individual gravity data for the localized departures from this average (using the laboratory value of *G*, 6,672 × 10^{-11} m^{3} kg^{-1} s^{-2}). This correction procedure was a fully three-dimensional one since we have a detailed picture of the geological structure and density of the region. The corrected gravity data were then used to calculate *G* (as in ref. 3). A small iterative adjustment was then applied by using the calculated value of *G* in repeating the corrections to the *g* values, but the effect on the estimate of *G* was not significant. Thus the density measurements were used to obtain representative densities of the iden-

Hilton mine: $g_0 = 9.786$ m s^{-2}; $\phi_g = 20°34'$ S; height above sea level = 386 m. $X(z)$ values assume the reference density, 2,750 kg m^{-3}.

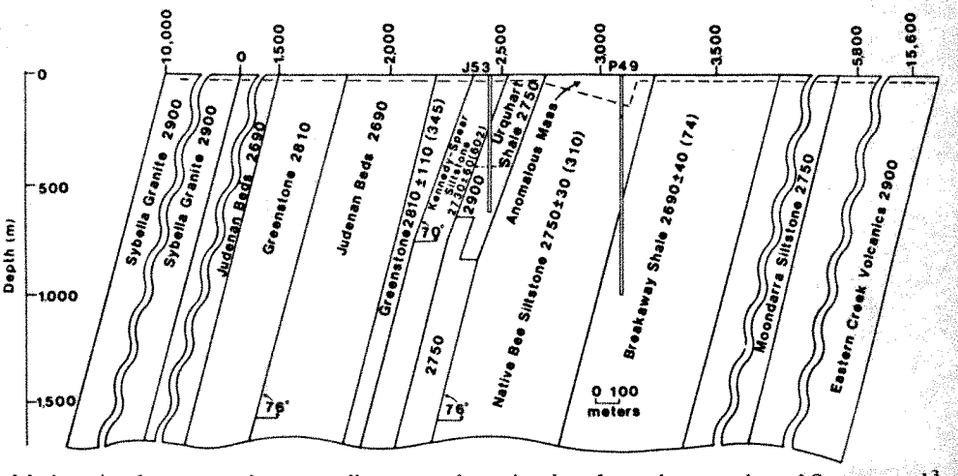

Fig. 1 Schematic cross-section of the rock formations of the Hilton mine (looking north). Structural trends are N–S, so that this cross-section is representative. Calculations assume the structure to extend to 4.5 km depth. Density values are given with standard deviations of individual samples about the means and the numbers of samples from each formation in parentheses. Gravity profiles were obtained for both shafts, but the greater homogeneity of rocks immediately surrounding the P49 shaft made this much more useful for calculating G.

tified geological formations instead of being simply averaged. The important difference between these procedures is that it avoids the bias of over-sampling of rocks that happen to be geologically interesting. Treatment of the density data for Urquhart shale required particular care, because this rock has some mineralization, but almost half of our density values were from it. The estimated mean density is a weighted average of the mineralized and unmineralized zones.

Special consideration is required for the density of the top 100 m or so of rock. This zone is weathered, porous and fractured, so that reliable and representative density data are impossible to obtain. We therefore chose to ignore the surface data point in calculating G and to consider the gravity gradient from 183 m (the first subsurface gravity station) to 993 m depth. This profile is unaffected by a uniform surface layer of unknown density. It is, however, influenced by inhomogeneity of the surface layer and a surface gravity survey was used to provide a correction for this. The surface survey was first corrected for the known deeper structure and then used to model a shallow mass to which we could attribute the residual gravity anomaly. This anomalous mass was then used to apply minor corrections to the subsurface g values; these corrections imply no knowledge of G, since they are based directly on comparisons of g.

All gravity data and corrections are listed in Table 1. The gravity values are corrected for instrumental drift and tides; topographic effects are insignificant. Excavation corrections are also included but these were made very small by mounting the gravity meter on a tripod near to the geometrical centre of a tunnel when a measurement is made. The first of the correction terms, as listed, was calculated assuming the laboratory value of G and was therefore re-weighted in the final calculation; the second is based on gravity measurements and so makes no assumption about G. $U(z)$ and $X(z)$ are depth-dependent parameters as defined by Stacey *et al.*[3].

The effectiveness of the density modelling is attested by the small scatter of gravity data from the equation of Stacey *et al.*[3] and consequently in the formal uncertainty of the calculated value of G:

$$G = (6.730 \pm 0.003) \times 10^{-11} \quad \text{m}^3\,\text{kg}^{-1}\,\text{s}^{-2}$$

The quoted uncertainty represents one standard deviation and is clearly smaller than the possible systematic error in the measurement of density; it is simply an indication of the internal consistency in the data. This is also demonstrated by a plot of gravity residuals (Table 1, Fig. 2), that is the departures of the gravity data, relative to the surface value, from the values calculated assuming the laboratory value of G. We interpret the intercept on the graph of residuals to be primarily a result of poor density values for the surface layers, although in principle it could be used to infer the range of a supposed short range repulsive force additional to normal gravity. We cannot explain the poor fit of the data point at 183 m. If this is omitted then we obtain

$$G = (6.734 \pm 0.002) \times 10^{-11} \quad \text{m}^3\,\text{kg}^{-1}\,\text{s}^{-2}$$

We are satisfied that inadequate knowledge of density must now be discounted as an explanation for the high values of G calculated here; this is probably true also for some of the earlier values and certainly for the marine measurement[4]. The remaining doubt arises from the possibility of a regional bias in the gravity gradient, as would be apparent if we could make a satisfactory direct measurement of the free-air gradient above the Earth's surface. The headframes at Hilton are not high enough to obtain satisfactory free-air gradient data. If we are to explain our observations in terms of conventional (newtonian) physics, we require a mass distribution at depth to give an anomalous vertical gradient of -2.1 mgal km^{-1} (1 gal = 10^{-2} m s^{-2}) (as in Fig. 2). For this gradient to be consistent to 10% over the top kilometre, as is apparent, the depth of the mass must be not less than 30 km. (It could be shallow and

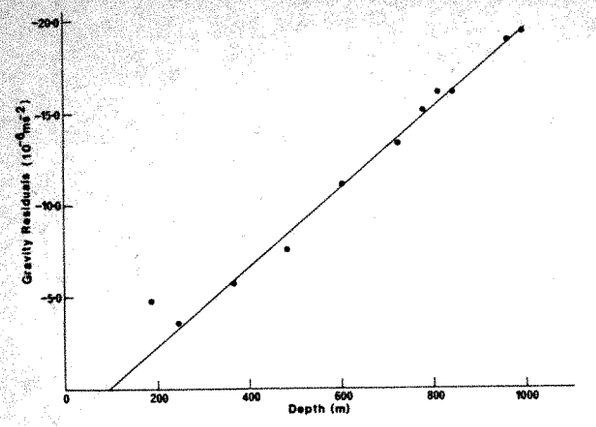

Fig. 2 Gravity residuals, calculated as differences between measured gravity at depth, relative to the surface, and values expected from the laboratory value of G.

laterally extended, but the calculations are similar.) Such a mass would cause a local gravity anomaly of about 30 mgal over a horizontal scale of about 30 km and would give a horizontal gradient greater than the locally observed one. However, the anomaly is comparable with the strongest of the observed gravity anomalies in the region[6] so although it does not provide a convincing explanation for our observations, it introduces an element of doubt that we cannot dismiss with certainty.

Our value of G is the best controlled of the geophysical determinations, all of which are higher than the laboratory value[4], and it falls into the middle of the range. Although we are not prepared, at this stage, to assert that a non-newtonian effect is clear and proven, the circumstantial evidence is very strong indeed. The need for a deep-sea measurement, as originally proposed[2], is now urgent.

This work is supported by the Australian Research Grants Scheme and by Mount Isa Mines Ltd. We appreciate the help of Mount Isa Mines staff, especially, R. Blair, J. Gillam, M. Lee, G. Orthman and J. Rogan, and the opportunity to make full use of company data. F. D. Stacey gave us detailed advice at all stages. This work will be presented elsewhere[7].

Hyperion: 13-day rotation from Voyager data

P. Thomas*, J. Veverka*, D. Wenkert†, G. E. Danielson† & Merton E. Davies‡

* Center for Radiophysics and Space Research, Cornell University, Ithaca, New York 14853, USA
† California Institute of Technology, Pasadena, California 91125, USA
‡ RAND Corporation, Santa Monica, California 90406, USA

The spin period and orientation of Hyperion have remained uncertain even with high-resolution Voyager images. We have now used low-resolution Voyager images taken over a two-month span to seek a rotational light-curve. The data indicate a spin period of 13 days, with the spin axis nearly parallel to the orbital plane.

Hyperion, an irregularly shaped satellite (maximum dimension about 350 km), orbits Saturn between Titan and Iapetus once every 21.3 days. Because of the satellite's small size and large distance from Saturn, Peale[1] suggested that Hyperion's spin period may not be synchronous with its orbital period. The actual spin or rotation rate of Hyperion is of interest not only for dynamical reasons, but also in the context of understanding the albedo dichotomy on Iapetus[2,3]. One popular explanation of Iapetus holds that dark dust spiralling into Saturn on retrograde orbits preferentially coats the leading hemisphere of Iapetus[3], a scenario that implies that some of this dark dust is also intercepted by Hyperion. If Hyperion, like Iapetus, had a synchronous spin state one might expect to see large albedo differences between its trailing and leading hemispheres. Voyager images reveal no evidence of a hemispherical albedo dichotomy on Hyperion[4].

Initial attempts to derive the rotation period of Hyperion from the highest resolution images obtained by Voyager 2 were not successful[4]. In this study we determine the rotation period by means of a light-curve derived from low-resolution Voyager images. We exclude the high-resolution, high phase-angle images obtained within a period of about one day, because during this period changes in the appearance of Hyperion reflected the rapid motion of the spacecraft rather than the intrinsic rotation of the satellite. Our analysis is restricted to nineteen images obtained through the clear filter ($\lambda_{eff} \sim 0.48\ \mu$m) of the narrow angle cameras: five Voyager 1 images taken over 27 days from 26.5×10^6 km to 4.6×10^6 range, and fourteen Voyager 2 frames taken over 61 days from 59×10^6 to 1.8×10^6 km. The Voyager 1 data were from 14 October–10 November 1980 and Voyager 2 data 24 June–23 August 1981. For each image a disk-integrated brightness was obtained and scaled to a common distance. Corrections for phase effects were made starting from intrinsic phase coefficients of the surface material determined from the high resolution images at phase angles $\alpha = 25°$ to 45°. The resulting average disk-integrated phase coefficients[5] ranged from 0.019 to 0.020 mag per degree, and were used to scale the data to our reference frame (FDS 43323.29) obtained at $\alpha = 6.3°$. The single image below a phase angle of 4.0° ($\alpha = 2.85°$) was scaled using a phase coefficient of 0.03 mag per degree to allow for the possible presence of an opposition surge[6]. The calculated phase coefficients are consistent with those derived for other satellites of Saturn[7,8], and the precise value adopted has little influence on the light-curve analysis.

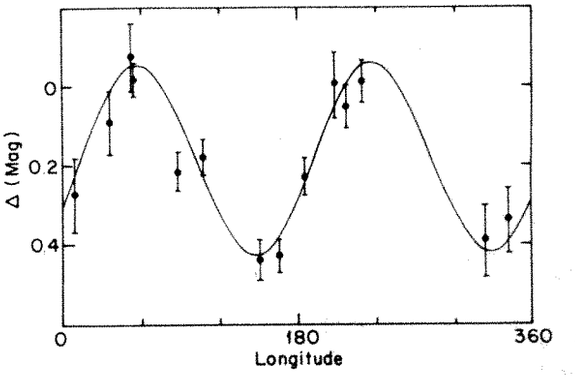

Fig. 1 Hyperion light-curve from Voyager 2 clear filter data, for a period of 13.1 days, rotation axis parallel to Hyperion's orbital plane. The observations are compared to a simple sine curve; error bars are estimated uncertainties due to phase function and photometric noise.

Uncertainties in the disk-integrated values used to construct the light-curve arise from two major sources. First, there is photometric noise given the very small scale of most of the images (1–5 pixels across). Second, for an object as irregular as Hyperion, corrections for differences in solar phase can only be made approximately, and corrections for variations in aspect must be ignored at this level of analysis. The resulting estimated uncertainties in the scaled brightness levels range from 4 to 10%.

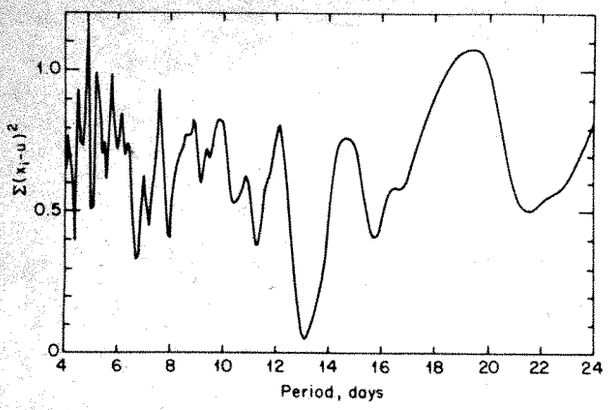

Fig. 2 Residuals of Voyager 2 observations (x_i) compared with a sine curve light-curve (u) as a function of rotation period. Differences in the orientation of the rotation axis produce only small differences in the residuals. The only good fits correspond to periods of 13.1 ± 0.3 days.

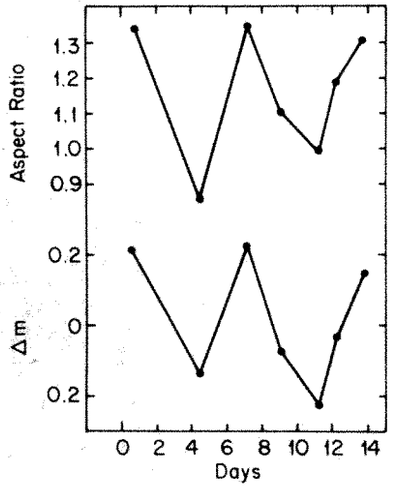

Fig. 3 The aspect of Hyperion and observed light-curve during the final 14 days of Voyager 2 approach data. The aspect ratio is the apparent dimension perpendicular to orbital plane divided by dimension parallel to orbital plane. The similarity of the two curves demonstrates that the light variations are primarily due to variations in the satellite's apparent shape, and that the spin axis is more nearly parallel to the orbital plane than perpendicular to it.

The available data indicate a spin period of 13 days (Figs 1 and 2). The result does not depend strongly on the assumed direction of the spin axis, because during each of the two sequences available the relative angular motions of the spacecraft and Hyperion were small. In Fig. 1 the Voyager 2 data are compared with a simple sine curve of period 13.1 days (the points cover five rotations of the satellite). By themselves, the five Voyager 1 points cannot be used to determine a period, but they are consistent (period and amplitude) with the light-curve shown in Fig. 1. Figure 2 shows the residuals between the Voyager 2 data and model sinusoidal lightcurves as a function of period. The only acceptable fits correspond to periods of 13.1 ± 0.3 days. If we use the estimates of uncertainties (see Fig. 1) a strong minimum occurs at the same period. Because the total uncertainties are not known, a formal χ^2 test is not appropriate.

We now turn to the possibility of determining the orientation of the satellite's spin axis. The last 14 days of Voyager 2 observations (seven images) obtained sufficient resolution to estimate the satellite's apparent shape. The longest dimension was found to be nearly perpendicular to Hyperion's orbital plane. The resulting aspect ratios (north-south dimension divided by east-west dimension) are shown in Fig. 3. It is evident that the light variations observed are due to changes in the apparent shape of the satellite as it rotates around its spin axis and that the rotation axis must be nearly parallel to the orbital plane. The maximum Voyager 1 elongation (at maximum integrated brightness) was also nearly north-south and had an aspect ratio of 1.3.

Recently, Wisdom, *et al.*[9], have suggested that Hyperion's spin state might be chaotic with substantial variations in both the period and the orientation of the spin axis on time scales of several orbital revolutions (period = 21.3 days). Our Voyager 2 data indicate a coherent 13-day spin period over 61 days, or nearly three orbital revolutions. Our data are also consistent with the view that Hyperion's spin period and spin axis orientation were similar 220 days earlier at the time of the Voyager 1 observations.

Our results show that Hyperion is definitely not in synchronous rotation. Consequently it cannot be used to test the hypothesis that dark dust spiralling inward on retrograde orbits causes the pronounced leading side/trailing side albedo asymmetry observed on the surface of Iapetus.

We thank Candy Hansen, Anne Bunker and Andy Collins at the Jet Propulsion Laboratory, Pasadena for their efforts in preserving these satellite sequences in the mission design. This research was supported in part by NASA grant NAGW 193, and Rand Corporation Contract NASW 3602. This is contribution no. 3987 of the Division of Geological and Planetary Sciences at California Institute of Technology.

Spatial structures generated by chemical reactions at interfaces

David Avnir & Michael Kagan

Department of Organic Chemistry, The Hebrew University of Jerusalem, Jerusalem 91904, Israel

Far-from-equilibrium networks of physicochemical processes may exhibit structuring[1], in time (for example, chemical oscillations[2]), in space (stationary patterns[3]) or as a combination of both (chemical waves[4]). Much experimental effort has been invested during the past two decades in temporal and spatio-temporal phenomena[2,4]; and except for periodic precipitation processes[5] no general chemical system was available for a wide experimental study of the evolution of spatial structures. Recently, however, we have revealed a remarkably wide family of processes which produce spatial structures: chemical reactions at liquid interfaces. These include reactions at gas/liquid interfaces[6], and photochemical reactions at liquid/air[7,8] and liquid/liquid[8] interfaces. We now report yet another important class: reactions at membrane surfaces, as shown in Fig. 1. Although hydrodynamic slow currents are apparent at a mature stage of the structure development, the actual mechanism leading to the initial structuring is as yet not clear. We show, however, that these structures are not a visualizing method of patterns caused by evaporative cooling[9,10]: structures are formed also in the absence of such patterning and hydrodynamic currents start only after chemical structures are formed. Some of our observations suggest that chemical reaction is necessary for structure evolution, and that gravity apparently plays no role in this phenomenon.

The recognition that a much wider phenomenon lies behind Möckel's report[11] on structure formation in certain photo-

chemical reactions, has been developed through recent exploratory research. First, we reported that almost any photo-halogen cleavage, followed by a thermal halogen reaction produced spectacular far-from-equilibrium structures[7,8]. It was then shown by Micheau *et al.*[9,10], and later by us[12] and by others[13,14], that light-energy can be used quite generally to drive reacting systems away from equilibrium thus forming structures of photo-products. We were able then to substitute energy influx through the liquid interface, by matter influx, and showed that the reaction between a diffusing gas and a reactant in solution proceeds in a nonhomogeneous structured way[6]. An interface which is of special importance because of its role in biology, is that between two reacting solutions separated by a membrane. We report now that dissipative[1] structures are formed near the surface of a dialysis membrane (Spectropore-2, molecular cutoff 12,000) when one species diffuses through the membrane and reacts on the other side; the phenomenon is general from the chemical point of view (Table 1). All types of structure-formation systems described above share in common the sequence of events shown in Fig. 3. The membrane reactions were carried out as follows: A Perspex cell, having two compartments 5 cm in height, separated by the membrane, was filled up with the two solutions, one in each of the compartments. In all reactions (see Table 1 and Fig. 1) a solution of a small species is separated from a dilute solution of a larger substrate, so that diffusion is virtually unidirectional. The coloured product is also a large molecule. The following observations indicated in Table 1 should be especially noted: (1) completely unrelated reactions produce similar patterns. As was found in our previous systems, the nature of the chemical reaction is of secondary importance. In fact, this generality raises the question of how this observation has been overlooked so far. We have referred already to this question when we described the gas/liquid structures[6], and suggested that the observation has been overlooked firstly because of the relative lack of awareness in chemistry to the importance of macroscopic structure-building processes; and secondly, because reactions are usually carried out under stirring: any structure formed would have been destroyed. (2) The

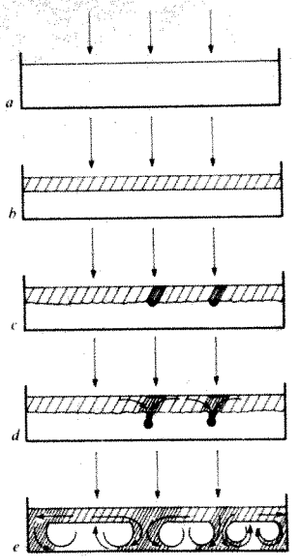

Fig. 3 *a*, Before reaction starts, whether photolytic, gas/liquid or liquid/liquid, the reactants solution is homogeneous and at rest. *b*, The reaction starts over the entire interface. *c*, After about 60 s lines of higher concentration begin to appear. *d*, The product descends along the pattern lines. If the interface is at the bottom the product *ascends*. *e*, If the solution is shallow enough (about 15 mm) the descending product forms hydrodynamic rolls. The solution eventually becomes homogenous again (not shown).

Fig. 4 An iodine–starch pattern formed by photolysis of KI/chloralhydrate/starch at 254 nm.

I_2/starch structures were produced not only through a membrane, but also by photooxidizing an I^-/starch solution[7,11] (Fig. 4, see below), and by I_2 vapours diffusing through starch solution interface[6]. The generality of the nature of the interface in this phenomenon is thus shown. (3) Comparison of reactions 2 and 3 (Table 1) suggests that gravity is not playing a deciding role in the overall mechanism. This is also suggested when photochemical structure-forming systems are irradiated from the bottom through a glass/liquid interface (refs 10, 12 and the Fe(III) photoreduction described below). (4) Note that in the cases where diffusion was not accompanied by a chemical reaction, structures did not form (reactions 10 and 11 in Table 1).

The apparent similarity between the patterns described and bulk hydrodynamic patterns[15] suggests the possibility that the patterns are colour tracing preexisting evaporative hydrodynamic currents (prepatterns)[9,10]. However, we present evidence that chemical patterns evolve in the absence of any evaporative prepatterns.

A number of experiments have been carried out with the photoreduction of Fe(III) to Fe(II) (ref. 16). A Petri dish filled with 5–10 mm of an aqueous solution of 0.2% oxalic acid dihydrate, 0.2% potassium ferricyanide and 0.1% ferric chloride hexahydrate (solution (1)) was irradiated from above at 360 nm (4 × 15 W lamps). The ferrous ions produced in this reaction form $Fe_3[Fe(CN)_6]_2$ (Turnbull's blue). This photochemical reaction, which produces patterns, was found to be experimentally more convenient than our previously reported photochemical reactions[7,8]. Evaporative currents in this system can easily be followed by sprinkling aluminium dust and illuminating from the side with a laser. To avoid the evaporative patterns, the Petri dish was sealed tightly with a glass cover. As expected[15,17], the evaporation patterns disappeared and no other convections could be detected. The liquid/air interface was then irradiated through the seal: beautiful blue structures were formed (Fig. 2*a*). The sequence described in Fig. 3 was very clear: first, the surface was homogeneously charged with the photoproduct (again, evaporation would clearly be seen at this stage); after about a minute, patterns started to grow; and finally bulk movements appeared when the photoproduct started to descend from the line-patterns at the surface, that is, the onset of currents is a later stage, and not a prerequisite, in this phenomenon.

In a second experiment on this photochemical system 25% methanol was added in order to enhance the evaporative patterns. Such binary systems are known to have pronounced patterning[15,18]. The initial experiment was repeated and compared to an open Petri dish irradiation. Although we cannot rule out the possibility that the produced patterns in the open vessel coincide with the evaporative patterns[10], it is our observation that the evaporation in fact interferes with an ordered still growth of the patterns. Furthermore, we found it extremely difficult to get chemical patterns in open vessels containing

liquids of very high vapour pressure such as methylene dichloride[8].

In a third experiment the Petri dish was filled with solution (1) to the rim, and then covered with a 3 mm sheet of glass, that is, the liquid/air interface was replaced by a liquid/glass interface. Obviously there is no evaporation in this system , yet structures developed in the usual way (Fig. 2*b*). Similarly, structures were obtained when the Petri dish (either closed or open) was irradiated from below. These observations seem to exclude a Marangoni-type effect[14], which requires a free surface[19]. Structures appeared also upon irradiation of a very shallow layer, obtained by 'sandwiching' solution (1) between two glass plates separated by 0.95 mm. Pattern formation upon irradiation of a 1 mm layer was reported by Micheau *et al.* in an open system and attributed to preexisting currents[9,10]. However, a careful observation under a microscope of the sequence of events on irradiating one drop of (1) (~3 mm in diameter, less than 1 mm in height) revealed again the stages of Fig. 3, namely: first pattern formation at the surface and only then slow hydrodynamic currents.

Other evidence shows, as we have reported already[8], that irradiation of the following liquid interfaces, protected from evaporation by another 4 cm liquid layer, produced structures: diphenyl amine/CCl_4 covered by water; diphenylamine sulphonate/KBr/H_2O, covered by cyclohexane; 4-aminophenol·HCl/KBr/H_2O, covered by paraffin oil. The membrane experiments described in this paper again exclude the necessity for evaporative prepatterning for the chemical structures formation: the membrane is covered with a 5 cm layer, and protected at the sides by 2 cm Perspex walls.

Reactions 10, 11 in the Table (dye diffusion only) demonstrate that diffusion by itself is probably insufficient in accounting for the phenomenon, and that coupling with a chemical reaction is necessary. The quantitative evaluation and comparison of one dissipative structure to the other is a complicated, still uncompleted task that has been undertaken by us[12] and by others[17]. However, even at this early stage it seems to us that in many cases (for example, Fig. 4) one can tell qualitatively that the shapes obtained are in fact quite different from usual patterns seen in thermal convections[15].

Models and theories of far-from-equilibrium processes have predicted the feasibility of the formation of interfacial structures[20], yet to the best of our knowledge, the phenomenon we describe is the first wide family of chemical processes forming such structures. Quantitative parametrizations and simulations in the light of such models, and a study of an interesting scaling behaviour of the patterns[12], found during the microscopic experiment described above, are in progress.

A new chemical oscillator containing neither metal nor oxyhalogen ions

Maria Burger* & Richard J. Field

Department of Chemistry, University of Montana, Missoula, Montana 59812, USA

Essentially all known inorganic chemical oscillators[1] conta metal ion[2–4] and/or an oxyhalogen ion, in particular, io ion[3], bromate ion[2,5] or chlorite ion[6]. We report here a chemical oscillator that is based on sulphur chemistry and tains neither a metal ion nor an oxyhalogen ion. The oscil does involve elemental oxygen, and in this way it may be rel to an oscillating reaction recently discovered by Jensen[7]. discovery of new chemical oscillators which are fundamen different from those previously known is of great import as it supplies new testing grounds for general theori dynamic behaviour[8] as well as further information concer the exact mechanistic requirements for chemical oscillato occur.

The chemical oscillator is composed of sulphide ion, sul ion, methylene blue (which serves as a catalyst), and disso oxygen. During the reaction, the methylene blue catalyst cy lates between its oxidized, coloured form (MB^+) and its red leuko form (MBH). Figure 1 shows a typical oscillatory of the absorbance at 668 nm due to MB^+. Sharp puls oxidation are observed in which ~40% of the MBH is conv to MB^+.

The reaction is run in an aqueous medium of *p*H 12–1 in a continuous-flow, stirred tank reactor (CSTR). It is the known example of chemical oscillations in a basic solution three feedstreams contain, respectively, MB^+, Na_2S, Na and O_2 at the appropriate *p*H. The sulphide ion is esser completely tied up as HS^- at *p*H 12–13. Sulphite ion ex the range of feedstream reactant concentrations and re residence times for which oscillations are found. Howeve apparently not a major reactant as oscillations appear absence. Figure 2 shows the region in $[S_2^{2-}]$, $[SO_3^{2-}]$ const space for which oscillations occur at a particular flow oxygen concentration and methylene blue concentration experiment is run in CSTR mode both to maintain the che system far from thermodynamic equilibrium, a necessi sustained chemical oscillations[9], and to keep the reactan centrations, especially that of dissolved oxygen, in the oscil range. The dynamics of the flow does couple with the che dynamics. However, regular but irreproducible oscillation been observed (B. Miewald and R.J.F., unpublished data) the experiment is run in a batch reactor.

The quantitative behaviour of the reaction is rather se to impurities in the Na_2S used, mainly sulphite ion, polysu ion and thiosulphate ion. However, the reaction is quite ducible when care is taken to monitor and control impurities quantitatively.

Oscillations appear only in a rather small range of flow for a particular set of feedstream concentrations, and the c tory region is quite dependent on these concentrations. cally, the steady-state $[MB^+]$ is very close to zero at flow below the oscillatory region while at flow rates higher th oscillatory range it is substantially higher, approximati median $[MB^+]$ during an oscillation. Approach to steady may be very slow both above and below the oscillatory Bistability is a common feature of chemical oscillators CSTR mode[10]. However, we have not yet observed bis in this system. The search continues.

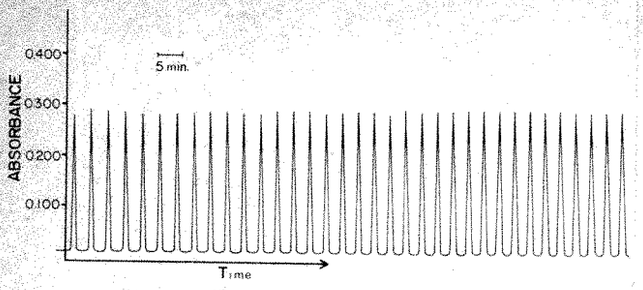

Fig. 1 Oscillations in the concentration of MB^+ as observed by measuring the absorbance at 668 nm. Conditions: $[MB^+]_0 = 3\times10^{-6}$ M: $[SO_3^{2-}]_0 = 1.2\times10^{-3}$ M: $[S^{2-}]_0 = 4.1\times10^{-2}$ M: $[HO^-]_0 = 5\times10^{-2}$ M: $[O_2]_0 = 1.5\times10^{-4}$ M. Temperature, 20 ± 0.1 C. 1/(residence time) = 1.5×10^{-3} s^{-1}.

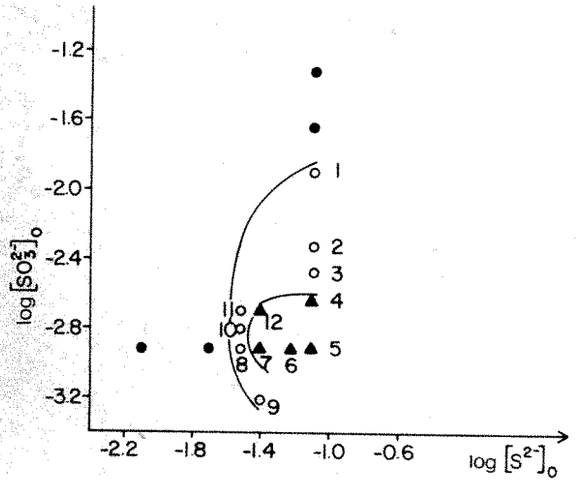

Fig. 2 $[S^{2-}]_0$ versus $[SO_3^{2-}]_0$ constraint-space diagram. Conditions: $[MB^+]_0 = 3.0\times10^{-6}$ M: $[OH^-]_0 = 5\times10^{-2}$ M: $[O_2]_0 = 1.5\times10^{-4}$ M. Temperature, 20 ± 0.1 °C. ○, Transient oscillations as the reciprocal residence times noted below are approached: ●, stable steady state; ▲, sustained oscillations. The reciprocal residence times are: (1) 1.9×10^{-3} S^{-1}; (2) 3.5×10^{-3} S^{-1} and 3.1×10^{-3} S^{-1}; (3) 3.1×10^{-3} S^{-1}; (4) 2.3×10^{-3} S^{-1} and 1.9×10^{-3} S^{-1}; (5) 2.0×10^{-3} S^{-1}; (6) 2.0×10^{-3} S^{-1}; (7) 1.6×10^{-3} S^{-1} and 1.3×10^{-3} S^{-1}; (8) 1.3×10^{-3} S^{-1} and 1.0×10^{-3} S^{-1}; (9) 1.5×10^{-3} S^{-1}; (10) 1.5×10^{-3} S^{-1}; (11) 1.3×10^{-3} S; (12) 1.3×10^{-3} S^{-1}.

The net stoichiometric chemical reaction which drives the oscillations is apparently reaction (1).

$$2SH^- + O_2 \rightarrow 2S + 2HO^- \quad (1)$$

The elemental sulphur may polymerize according to reaction (2),

$$nS + HS^- \rightarrow HS^-_{n+1} \quad (2)$$

or be removed from the system by sulphite ion according to reaction (3).

$$S + SO_3^{2-} \rightarrow S_2O_3^{2-} \quad (3)$$

Substantial amounts of elemental sulphur may precipitate in experiments where $[SO_3^{2-}]$ is low. However, this does not strongly affect the oscillations. Indeed, elemental sulphur may be added to the feedstreams with only minor effect.

This new oscillator was intentionally designed by the expedient of coupling an apparently autocatalytic reaction with a return mechanism. Reaction (4), the reduction of MB^+ by HS^-, is the apparently autocatalytic reaction[11].

$$HS^- + B^+ \rightarrow MBH + S \quad (4)$$

However, we have now found (unpublished data) that the reaction is not genuinely autocatalytic. It is instead inhibited by oxygen, which must be removed before the reaction can begin. A similar inhibition has been observed in the reduction MB^+ by sulphydryl compounds[12] such as cysteine. We have been unable to observe oscillations in the present system when sulphide ion is replaced by cysteine.

The return step is the oxidation of MBH by O_2. There is evidence[13] that this reaction actually is autocatalytic.

An explanation of the mechanism of this oscillator must await further detailed information on the component reactions. This work is underway.

This work was supported by the NSF under grants CHE77-03599 and CHE80-23755. We acknowledge the work of Bruce Miewald who first saw the methylene blue oscillations during the summer of 1978.

Evidence for stabilization of the Pilbara Block, Australia

T. S. Blake

Department of Geology, University of Western Australia, Nedlands, 6009 Western Australia

The stabilization of continental crust to form cratons represents one of the major features of Earth history[1]. Major structural, geochemical[2,3] and, to a lesser extent, sedimentological changes[4] associated with the development of stable crustal blocks are recorded mainly around 2,500 Myr ago[1]. This change, however, appears to have been globally diachronous and cratonic sequences as old as 3,100 Myr are recorded[5]. I now present the results of a recent regional stratigraphical and sedimentological study on the ~2770 Myr old lower Fortescue Group[6,7] (previously classified lithologically as Proterozoic[8], but following the recent recommendation of a 2,500-Myr Archaean/Proterozoic chronological boundary[9] is referred to as Archaean) in the Pilbara Block[10], Western Australia. A major stabilization of the underlying granitoid–greenstone terrain appears to have pre-dated Fortescue basin formation. This event, which available geochronology suggests was relatively rapid, marked a major changing point in the tectonic evolution of the Pilbara Block.

The lower Fortescue Group (Fig. 1) comprises shallow-dipping, very low-grade[11] flood basalts, clastic sediments and tuffs which rest unconformably on a deformed 3,500–2,850 Myr old granitoid–greenstone terrain[12], the Pilbara Craton[10]. The age of the Fortescue Group is constrained by: (1) 2,847 ± 34 Myr, Pb–Pb whole rock age from a post-tectonic granitoid in the underlying Archaean craton (U.W.A., unpublished data, revises previous Rb–Sr ages[13,14]). (2) 2,768 ± 16 Myr, U–Pb zircon age from a porphyry with the lower Fortescue Group (R. T. Pidgeon, personal communication) that was originally considered intrusive[15] but is now reinterpreted as having an erosive upper contact (upper Unit 2, East Pilbara Basin, Fig. 2). (3) 2,490 ± 20 Myr and 2,470 ± 30 Myr, U–Pb zircon ages from the overlying Hamersley Group[16]. The basal unconformity

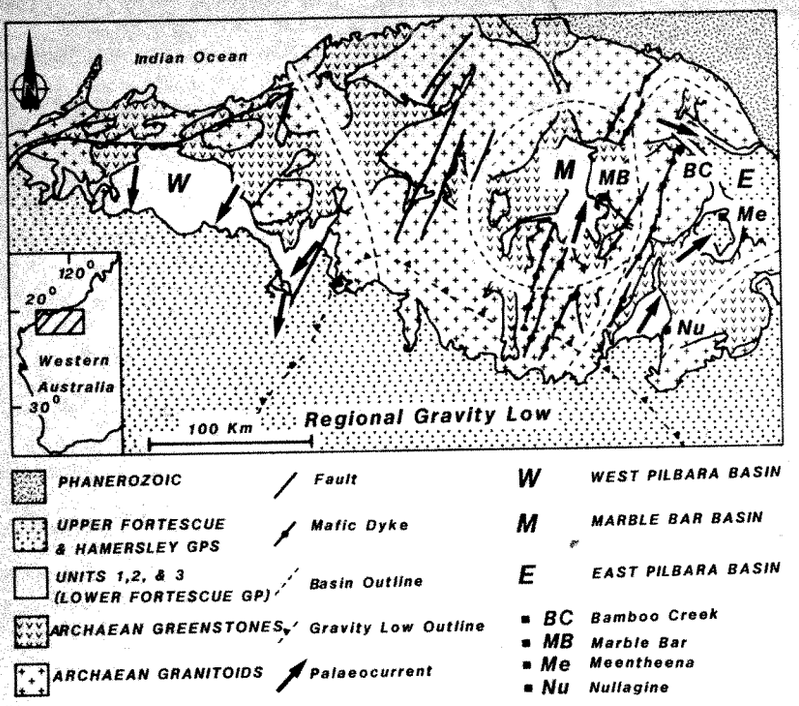

Fig. 1 Location of study area, outline of early Fortescue Group basins and unit 3 palaeocurrents.

(Fig. 2) therefore probably represents a maximum hiatus of ~130 Myr, although the contact between the dated Archaean post-tectonic granitoid and the lower Fortescue Group is not seen.

Three discrete lower Fortescue basins have been recognized, the West Pilbara, Marble Bar and East Pilbara Basins (Fig. 1). These are lithostratigraphically correlated using regional intra-Fortescue unconformities which divide the revised stratigraphy into three major units (Fig. 2). These units sequentially reflect a change in tectonic controls on sedimentation.

Unit 1 comprises a discontinuous basal clastic sedimentary horizon commonly <30 m thick, overlain by up to 2,000 m of subaerial to shallow-water flood basalt. In the Marble Bar Basin, however, up to 500 m of fluvial sandstone and conglomerate exists beneath the basalt. The local derivation of sediment (from Archaean granitoids and greenstones) and converging fluvial palaeocurrents suggest deposition in an enclosed basin centred over greenstones (Fig. 3). Deformation preceded unit 2 sedimentation, resulting in dips of 5–20° towards the centre of the earlier sedimentary basin. Local close to tight folding (dips 50–60°, in places vertical) formed a sinuous central belt of upright, shallow-plunging structures (Fig. 3). This style of deformation is similar to the main upright deformation affecting the underlying greenstone belts which has been assigned to diapiric movements on surrounding granitoids[17].

Unit 2, unconformably overlying Archaean greenstones and unit 1, exists only in the East Pilbara and Marble Bar Basins (Fig. 2). In the East Pilbara Basin it comprises a poorly exposed fluvial and lacustrine sequence overlain by an intrusive and extrusive acid porphyry complex. In the Marble Bar Basin, unit 2 mainly comprises subaerial to shallow-water basaltic lavas with complex interdigitations of sediments near the base. Most of the sediments, which are of granitoid provenance, are preserved as three, up to 80 m thick, upward-coarsening sequences (shale/silt to sandstone/pebble conglomerate) deposited axially in an elongate basin ~15 km wide and at least 40 km long. Initial fluvial sedimentary input was from the north with a later influx from the south-east. The coarsening upward sequences probably resulted from fluvial progradation into a lacustrine environment. The cyclicity of sedimentation suggests an active fault control, although the exact positions of these faults are unclear. Most observed fractures were generated by major post-unit 2 movements. The style of sedimentation, in possibly fault-controlled belts with laterally persistent stratigraphy and a more

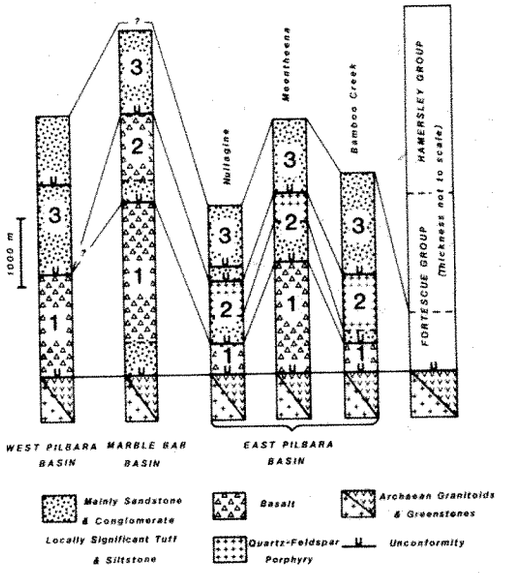

Fig. 2 Stratigraphical position of units 1, 2 and 3 and revised stratigraphy (cumulative maximum thicknesses).

uniform provenance, is in marked contrast to the sedimentation in unit 1, although in both units sediment accumulated over greenstone belts.

Unit 3 is dominated by granitoid derived sandstones with pebble conglomerates and minor coarser conglomerate, except in the West Pilbara Basin where it is mainly composed of epiclastic volcanic sediments. Fluvial palaeocurrents (Fig. 1) indicate axial sediment dispersal in linear troughs centred over greenstone belts. These basins were ~20 km wide and at least 100 km long (satellite imagery suggests the main north–north-east trending East Pilbara Basin structure may have been >250 km long). Fault-controlled local marginal alluvial fan systems (up to 1 km thick) suggest deposition in part in elongated graben structures. Active basin margin faulting apparently became less important towards the top of unit 3, sedimentation patterns remained linear and parallel to the underlying troughs, although basins became significantly wider and marginal sedimentation overlapped earlier growth faults.

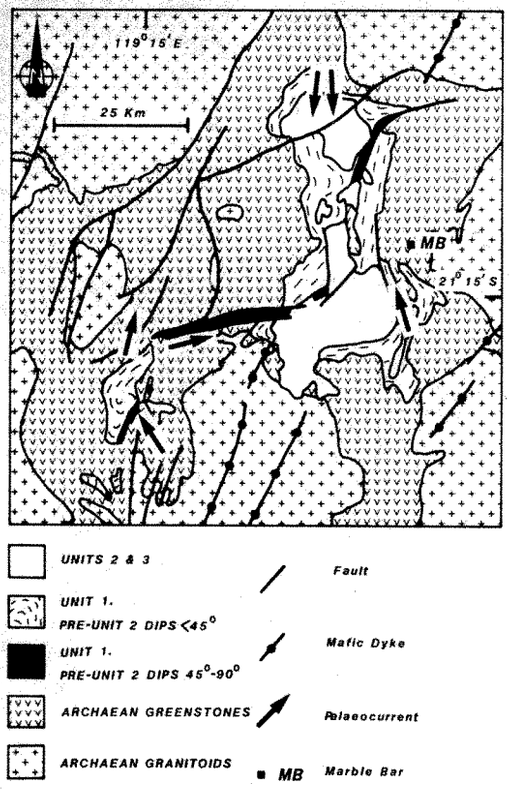

Fig. 3 Marble Bar Basin, unit 1 palaeocurrents and deformation belt.

Unit 3 palaeoccurent data (Fig. 1) indicate a northward palaeoslope in the Marble Bar and East Pilbara Basins and a southward palaeoslope in the West Pilbara Basin. Unit 3 was not deposited between these two regions where units higher in the Fortescue Group overlap the Archaean basement. Bouguer anomalies[18] show a regional gravity low in this area, probably reflecting a preponderance of low density granitoids in the underlying Archaean craton. Such an area would have been prone to gravitational uplift and appears to have been a topographic high during deposition of the lower Fortescue Group[19].

In the East Pilbara large (up to 100 km long and 150 m wide) north–north-east trending undeformed mafic dykes cross-cut Archaean granitoids and greenstones. The relationship between these and the lower Fortescue Group is generally inconclusive, although the latest phases clearly post-date unit 2 and probably unit 3.

The lower Fortescue Group sedimentary stratigraphy reflects an increasing fracture control on sedimentation culminating in >250 km long, mostly north–north-east trending, fractures during unit 3. Initially, sedimentary basin geometry and deformation may have been locally controlled by minor intra-cratonic diapiric movements on Archaean granitoids. The effusion of extensive flood basalts during unit 1 (now preferentially preserved over greenstone belts), however, suggests that basins were initiated under a tensional regime. Fracturing became less important during the upper part of unit 3 and a more regional subsidence is apparent, resulting in the probable unification of all three initial basins during upper Fortescue and Hamersley times. The north–north-east trending mafic dykes (possibly feeders to some of the basalts) cross-cut the Archaean craton irrespective of lithology or structural trends, exploiting the same fracture system that controlled sedimentary basins. This disregard for Archaean crustal trends and the inferred tapping of deep magma sources suggest failure of the lithosphere rather than the crust.

The initiation of Fortescue Group accumulation appears to have been caused by the superimposition of a regional tensional regime on a stabilized Archaean granitoid–greenstone terrain, although inferred minor diapiric movements suggest that some internal mobility remained. A significant lithospheric thickening and associated stabilization during the 130 Myr between the latest Archaean plutonism and initial Fortescue deposition would account for a change from crustal to lithospheric dominated tectonics. Although the causes of such an event remain speculative, a localized rapid decrease in heat flow[20,21] would have such an effect. In this context, it is noteworthy that the proposed period of cratonization ($\leq$130 Myr) is of the order of the present thermal time constant[22]. A rapid local decline in heat flow and subsequent lithospheric thickening and stabilization, as opposed to a secular global decrease, accords with the worldwide diachronous record (3,100–2,500 Myr) of continental cratonization.

Cambrian and Ordovician conodonts from the Robertson Bay Group, Antarctica and their tectonic significance

Clive F. Burrett & Robert H. Findlay

Geology Department, University of Tasmania, GPO Box 252C, Hobart, Tasmania, Australia 7001

The Robertson Bay Group is a thick (>3,000 m) sequence of turbidites deposited in one or more submarine-fan complexes[1–3]. It is exposed throughout the eastern half of North Victoria Land and has been assigned variously to the Upper Precambrian[4] (on the basis of acritarchs and lack of body fossils), or to the Lower Cambrian[5] or Cambrian[2] (partly on the basis of trace fossils). We report here Upper Cambrian and Lower Ordovician conodonts in a limestone block within rocks mapped[3,6] as Robertson Bay Group in the southeastern part of North Victoria Land. This discovery necessitates a reappraisal of tectonic reconstructions of the pre-Mesozoic units of southeast Australia, New Zealand and Antarctica[7–17]. A reconstruction is proposed which includes correlation of the Lower Ordovician Greenland Group, New Zealand and the Upper Cambrian–Lower Ordovician Wierah Formation of southern Tasmania.

During the third German North Victoria Land Expedition (GANOVEX III) in the southern summer 1982–83, 4 kg

© 1984 Macmillan Journals Ltd

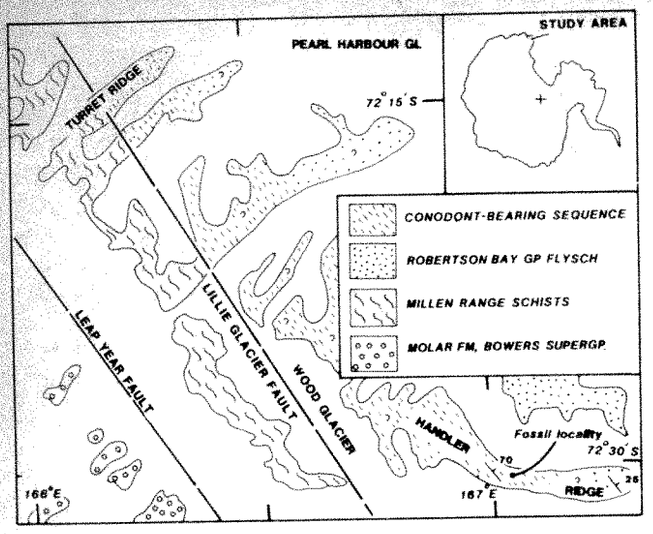

Fig. 1 Geological map of southeast part of North Victoria Land, Antarctica. East–west distance across map is 46 km.

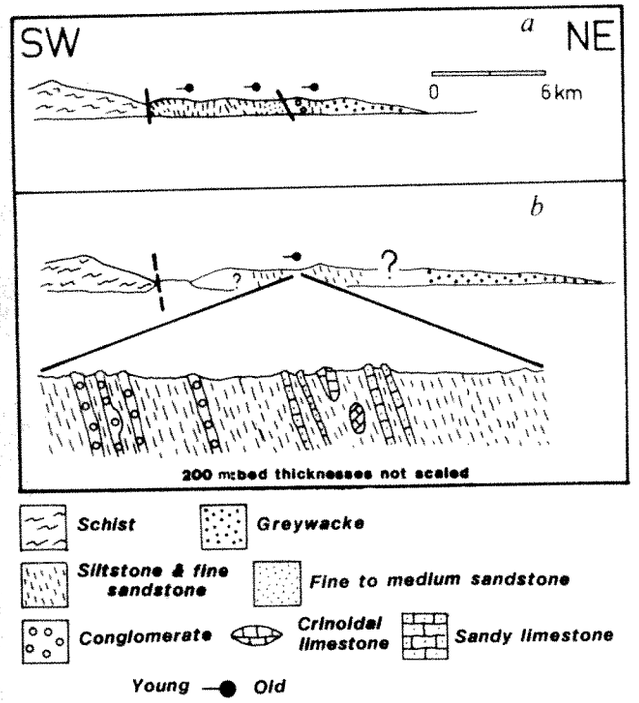

Fig. 2 Diagrammatic cross sections across *a*, Turret Ridge, and *b*, Handler Ridge.

of crinoidal intrabiosparite were obtained at Handler Ridge (Fig. 1) from a 1×0.5 m carbonate block within a sequence dominated by strongly cleaved, fine-grained, siliciclastics interbedded with subordinate, thin, matrix-supported siliceous conglomerate with pebbles of vein-quartz, limestone, chert and fine-grained sandstone and mudstone (Fig. 2). One fist-sized carbonate clast adjacent to the block has yielded a trilobite fauna currently being studied by T. Wright and colleagues in the United States. A similar sequence is exposed on Turret Ridge, some 30 km northwest (Fig. 1). Unfortunately, logistic problems prevented detailed stratigraphic logging of the section but the sequence appears to grade northeast into typical Robertson Bay Group turbidites.

Folds at the fossil locality plunge steeply (60–90°) in contrast to the generally shallowly plunging (0–25°) structures found in the Robertson Bay Group at the east end of Handler Ridge

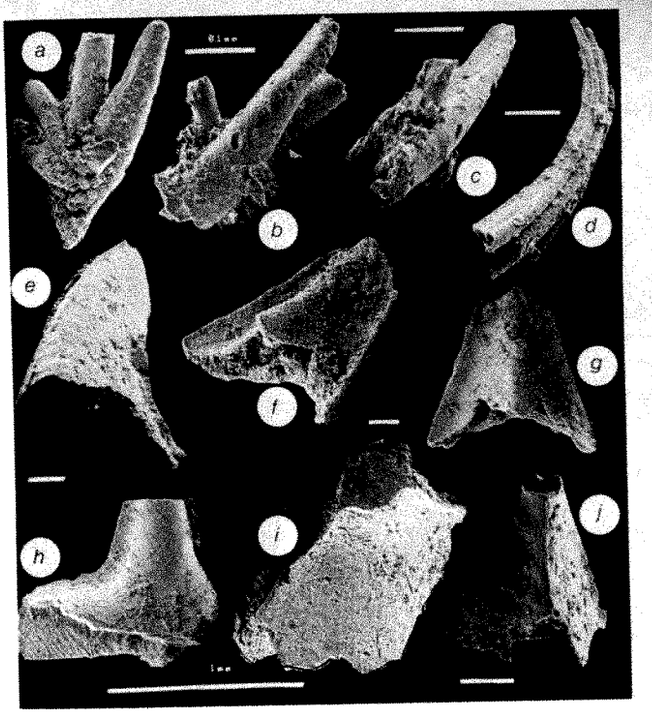

Fig. 3 Conodonts from limestone block within Robertson Bay Group, Handler Ridge. *a–c*, Fused assemblage of four elements of *Proconodontus posterocostatus* Miller 1980; *d*, *'Prooneotodus' tenuis* (Müller 1959); *e*, *Proconodontus* aff. *muelleri* Miller 1969; *f–g*, *Prosagittondontus* aff. *dunderbergiae* Müller 1959; *h–i*, *Iapetognathus* sp.; *j*, *Westergaardodina* aff. *bicuspidata* Müller 1959. Scale bar, 0.1 mm except for *h–i*, 1 mm.

and predominant[18,19] elsewhere in the Robertson Bay Group. However, this contrast is not diagnostic of a tectonic distinction between the rocks at the fossil locality and the more typical Robertson Bay Group rocks to the east, as the folds throughout Handler Ridge possess the same northwest-trending axial plane cleavage. This cleavage occurs throughout the Robertson Bay Group, and is axial plane to primary non-cylindrical folds in Robertson Bay Group rocks on the northeast side of Pearl Harbour Glacier[19] and elsewhere[18].

On acetic acid dissolution, the limestone samples yielded a fauna of paraconodonts, conodontophorids, inarticulate brachiopods and phosphatocopine ostracods. Also present are poorly preserved, indeterminate, asaphid trilobites.

The conodont fauna includes *'Prooneotodus' tenuis* (Müller 1959), *Prosagittodontus* aff. *dunderbergiae* (Müller 1959), *Furnishina* spp., *Problematoconites* sp., *Westergaardodina* aff. *bicuspidata* Müller 1959, *Proconodontus* aff. *muelleri* Miller 1969 and the Lower Trempealeauan zonal index[20], *Proconodontus posterocostatus* Miller 1980. Also present is a compound conodontophorid with an erect, laterally compressed cusp and wide basal cavity which is referable to the Tremadoc genus *Iapetognathus* Landing 1982 (Fig. 3) known from North America and Sweden. On present evidence[20,21] *Proc. posterocostatus* is restricted to the Lower Trempealeau (Upper Cambrian) and *Iapetognathus* to the Tremadoc (Lower Ordovician). The remaining conodonts are mainly Upper Cambrian species though some range into the Ordovician. It is probable that the abundant carbonate intraclasts within the limestone block contain the Upper Cambrian conodonts; judging from its unusually abraded and pitted nature, the *Iapetognathus* may have been reworked also. Therefore the conodont fauna provides only a lower age limit of Lower Tremadoc on the limestone block. An upper age limit of Upper Ordovician is provided by the asaphids[22].

Whole rock K–Ar radiometric dating[23] on slates in the Robertson Bay Group yield ages ranging between 450 and

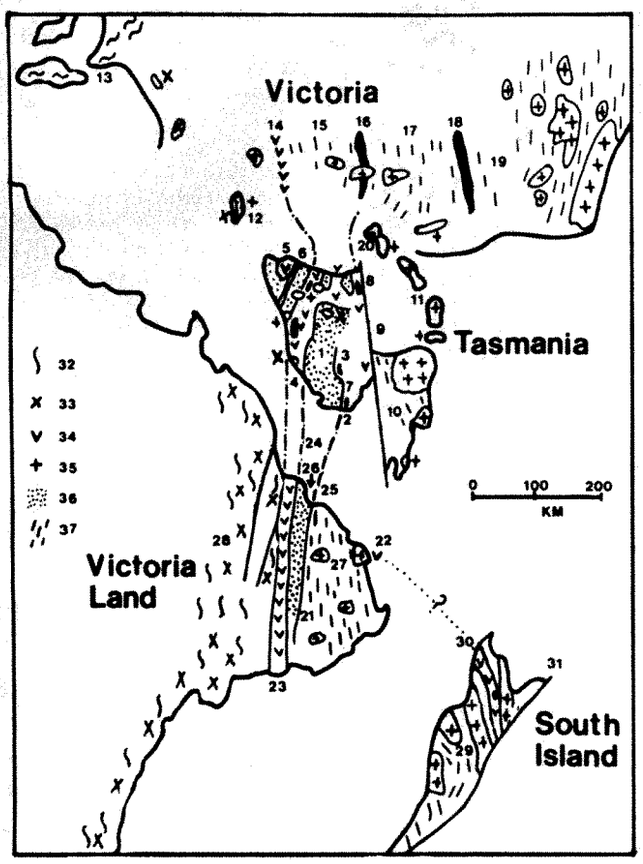

Fig. 4 Possible reconstruction of major blocks prior to Cretaceous break-up of Gondwanaland. 1, Tyennan Block; 2, South Coast Tasmania; 3, Adamsfield Trough with ultramafics; 4, Dundas Trough; 5, Smithton Basin; 6, Arthur Lineament; 7, Lake Edgar–New River Fault; 8, Beaconsfield ultramafic and Cambrian sediments and volcanics; 9, Tamar Fracture; 10, Mathinna Beds; 11, Bassian Rise granites; 12, King Island; 13, Kanmantoo Fold Belt; 14, Stavely Greenstone Belt; 15, Ballarat Trough; 16, Heathcote Greenstone Belt; 17, Melbourne Trough; 18, Mt Wellington Greenstone Belt; 19, East Victorian Metamorphic Belt; 20, Cape Liptrap-Waratah Bay; 21, Handler Ridge; 22, Unger Island volcanics; 23, Bowers Trough; 24, Leap Year Fault, 25, Lillie Glacier Fault; 26, Millen Range schist; 27, Robertson Bay Group; 28, high grade metamorphics, migmatites of the Wilson Group and correlates; 29, Greenland Group; 30, Central Belt of Cambrian volcanics and sediments (N. W. Nelson); 31, Alpine Fault; 32, relatively high grade metamorphics of the Wilson Group in Victoria Land and the Kanmantoo Fold Belt in South Australia; 33, late Precambrian-Ordovician granitoids; 34, Cambrian volcanic and siliciclastic sequences; 35, Devonian–Lower Carboniferous granites; 36, metamorphics of the Tyennan Block and the Millen Range; 37, relatively low grade turbiditic Palaeozoic fold belts of Victoria, Tasmania and New Zealand.

510 Myr. These ages are thought[23] to be metamorphic ages related to the Cambro-Ordovician Ross Orogeny, and therefore the sequence at Handler Ridge can be no younger than 450 Myr (that is, no younger than Llandeilo[24]).

The Robertson Bay Group, a simply-deformed sequence of Lower Ordovician and ?Cambrian turbidites intruded by Late Devonian granites, invites comparison with the Lower Ordovician–Lower Devonian turbiditic Mathinna Beds[25] of eastern Tasmania which are also intruded by Late Devonian granites. However, the Mathinna Beds contain neither conglomerates nor limestones, and a closer similarity appears to be with the recently described Wierah Formation on the south coast of Tasmania[26,27]. This formation overlies disconformably a sequence of turbidites belonging to the Point Vivian Formation. Thin limestone beds from the turbiditic lower part of the Wierah Formation contain an uppermost Cambrian conodont/phosphatocopine ostracod/brachiopod/trilobite fauna.

There is a considerable stratigraphic gap (~500 m) above the Wierah Formation but it is succeeded at Surprise Bay by a deep-water turbiditic carbonate sequence of Caradoc age (Upper Middle Ordovician)[28,29] in contrast to the peritidal carbonates that covered the western half of Tasmania in the Middle-Upper Ordovician.

Sedimentological evidence from the Upper Cambrian and Ordovician sediments on the Tasmanian south coast indicates palaeoslopes towards the south and southeast (refs 28 and 29 and K. Bischoff, personal communication). Derivation of Australian sediments, during the Ordovician, from the Robertson Bay Group, as suggested recently[30], is therefore unlikely. Instead, an Upper Cambrian to Ordovician basin may have existed to the (present day) south of Tasmania, parts of which are now present in southern Tasmania, North Victoria Land, and could be represented also by the Lower Ordovician turbiditic[31] Greenland Group of South Island, New Zealand (Fig. 4).

If the Robertson Bay Group and the Wierah Formation are aligned as in Fig. 4 then the Bowers Trough (no. 23 in Fig. 4), consisting of a Cambrian siliciclastic and volcanic sequence is aligned with the geologically similar Dundas Trough (no. 4 in Fig. 4) in western Tasmania. This alignment has been suggested several times before[8,14,16]. The recently proposed Lillie Glacier Fault[19] in North Victoria Land (no. 25 on Fig. 4) is aligned with the Lake Edgar–New River Fault (no. 7 on Fig. 4) and the newly described[19] schists in the Millen Range (no. 26 on Fig. 4) are aligned with the Precambrian metamorphics of the Tyennan Block (no. 1 on Fig. 4). Eastern Tasmania, along with the Bassian Rise granites (no. 11 on Fig. 4) and the Lower Palaeozoic sequence of Waratah Bay–Digger Island[32] in Victoria (no. 20 on Fig. 4) are displaced along the Tamar Fracture[25] (no. 9 on Fig. 4).

Future work in the Robertson Bay Group will assist delineation of the extent of the Lower Ordovician sediments and their relationships to surrounding areas.

This work results from the opportunity to participate in GANOVEX III, and we thank the expedition leader, F. Tessensohn for permission to publish. We thank T. O. Wright, K. Bischoff, B. Stait, and D. H. Green for their help, and the ARGS for financial support.

Biomass conversion to liquid fuels: potential of some Arizona chaparral brush and tree species

Edwin A. Davis*, James L. Kuester† & Marvin O. Bagby‡

* Rocky Mountain Forest and Range Experimental Station, Forestry Sciences Laboratory, and † Department of Chemical Engineering, Arizona State University, Tempe, Arizona 85287, USA

Arizona chaparral brush and tree species can be converted into high-grade liquid hydrocarbon fuels by indirect liquefaction in which pyrolysis is followed by catalytic liquefaction. Here we have examined various Arizona chaparral species and other woody plants for oil and hydrocarbon content and as biomass feedstocks for pyrolytic conversion to high-grade liquid fuels. Although no tested species contained enough oils or hydrocarbons to be considered useful sources, gasification data show that they are all promising biomass feedstocks for pyrolytic conversion to liquid fuels. Olefin yield from biomass gasification, which is an indicator of liquid hydrocarbon yield, may be influenced by feedstock composition. If some particularly outstanding biomass feedstocks were discovered, then manipulation of the vegetation to favour those species could be a management alternative to prescribed burning or chemical control. Because most of the chaparral species tested produced pyrolysis gas of comparable olefin content, however, harvesting of chaparral without regard to species composition is indicated.

Brushlands in the southwestern United States have been viewed as a low-value, relatively unproductive resource at best[1–5], or an extreme fire hazard at worst[6–9]. Attempts have been made to improve the productivity of chaparral and other brushlands using brush control treatments for the purpose of increasing streamflow duration and amount[10,11], augmenting forage for grazing[10,12,13], improving deer habitat[14,15], and reducing the spread of wildfires[16,17]. Under present practices these benefits must justify expenditures for treatment costs. Of the various benefits, increased grazing capacity generates the only return on capital investment. In the process of controlling brush, either through the use of prescribed burning or chemicals, a potentially valuable energy resource is sacrificed. An alternative to this process would be to harvest the brush on a rotation basis as a renewable energy resource for conversion into liquid fuels, densified fuelwood, or energy-rich chemicals.

In the present study, plant material for testing consisted of branches, stems and leaves of mature shrubs. The samples were reduced in a series of grinding steps (chipper, hammer mill and Wiley mill) to pass through a 6-mm screen. Analytical samples were ground still further to pass through a 1-mm screen. Analytical data are reported on an oven-dry basis. The solvent extraction scheme used to characterize the biomass feedstocks in terms of oil, hydrocarbon and polyphenol fractions is one used extensively by the US Department of Agriculture to discover energy-rich plants[18,19].

Test species were evaluated with respect to their oil and hydrocarbon contents in comparison with those of selected reference species (Table 1). None of the brush or tree species ranked with guayule in hydrocarbon content or with gopher plant in oil content. The polyphenol fraction is of interest as an indicator of tannin content and of reactive substances potentially valuable for making adhesives, phenolic resins, antioxidants and other products[20]. Of the species tested, sugar sumac gave the highest polyphenol value (16.3%) which compares favourably with the reference plant, smooth sumac (20.2%), once considered a commercial source of tannin[21]. Black greasewood contained considerably more crude protein than the other species; it compares well with gopher plant, which had the highest value, and with terminal twigs of several deer-browse shrubs[22] even though the greasewood sample contained much more woody material relative to terminal leafy twigs. None of the test species rated well as potential hydrocarbon- or botanochemical-producing species.

Biomass conversion options include biological processes to produce methane or alcohols, and thermochemical processes to produce heat, low- or medium-quality gas, oxygenated pyrolytic oils by direct liquefaction, or high-quality hydrocarbon liquid fuels by indirect liquefaction[23,24]. Thermochemical conversion via indirect liquefaction offers promise for converting biomass to high-grade transportation fuel equivalent to that derived from petroleum; the product would be compatible with existing engine design and the fuel distribution system. Three indirect liquefaction routes for biomass have been reported: (1) Naval Weapons Center (NWC) system[25]; (2) Mobil's system[26,27]; and (3) Arizona State University's (ASU) system[23]. All three systems use a synthesis gas. The NWC recommended an externally heated tubular reactor; Mobil technology did not address the gasification step; and the ASU system uses a fluidized bed with a circulating solid heat transfer system which converts unfractionated synthesis gas to a diesel-type fuel in a catalytic second stage.

A wide variety of feedstocks can be processed in the ASU system to a gas with a heating value of ~500 Btu per scf (standard cubic feet). Because biomass contains very little sulphur, the hydrogen sulphide content of the gas beyond the wet scrubber is negligible. Potential products include medium-quality gas, 1-propanol, paraffinic fuels (diesel, kerosene, jet), and high-octane gasoline. A key step is to tailor the pyrolysis gas composition with respect to carbon monoxide, hydrogen and olefins for use as a synthesis gas for the liquid fuels system.

The capability of the ASU system has been demonstrated with several feedstocks, for example almond prunings (from California orchards) and guayule bagasse (from bushes in Mexico). Composition of the pyrolysis gas is of high fuel value (about 500 Btu scf^{-1}) for all feedstocks, with minor variations in gas composition[28]. The water–alcohol phase for both feedstocks from the liquefaction reactor typically contains ~90% water by weight, 9% 1-propanol, and less than 1% other alcohols. Gas chromatograms of the liquid hydrocarbon products from various feedstocks are very similar in the C_7–C_{17} range and are similar to that of no. 2 diesel fuel; the major difference is the presence of C_7–C_9 compounds in the biomass liquid fuel products[28]. The biomass product should be directly usable as a transportation fuel without distillation. Properties of the undistilled biomass liquid fuel match those of JP-4 jet fuel more closely than those of no. 2 diesel fuel[28].

Factor studies in the laboratory have shown that pyrolysis gas composition is an adequate predictor of the capacity of biomass feedstocks to yield liquid fuel. Indicators of a high-quality pyrolysis gas are high olefin content and a H_2/CO ratio of 1.0–1.5. Most dry biomass feedstocks without water addition yield a H_2/CO ratio of 0.5–0.9. This ratio can be increased to the 1.0-1.5 range (and higher) by adding steam to the pyrolysis reactor fluidization gas to produce hydrogen and to deplete carbon monoxide via the water gas shift reaction ($CO + H_2O \rightarrow H_2 + CO_2$), with the reaction possibly catalysed by ash from the feedstock[28]. The optimal pyrolysis reactor fluidization gas appears to be a combination of steam and liquefaction reactor off-gas to supply higher molecular weight paraffinic hydrocar-

TABLE 1 Biomass feedstock analysis and gasification results

Biomass feedstocks		Feedstock analysis						Operating conditions			Pyrolysis reactor performance

The analytical values are based on a moisture-free whole plant basis. Ash and crude protein (calculated as Kjeldahl nitrogen times 6.25) were determined for separate subsamples. The pyrolysis fluidized medium was sand, and the fluidizing gas was recycled pyrolysis gas.

bons for cracking to olefins and hydrogen. Liquid fuel yields of ~40 gallons per ton of biomass can be expected when the pyrolysis gas has an olefin content of ~10 mol%.

A variety of rangeland brush and tree species representative of chaparral, desert shrub and woodlands in Arizona were tested through the gasification step. All biomass feedstocks were tested using recycled pyrolysis gas at 21–22 lb h^{-1} without steam addition. Although these conditions are not considered optimal for maximizing liquid fuel production, a relative assessment of the feedstocks can be made. Reference feedstocks were tested in similar conditions. The olefin content of the pyrolysis gas from 11 range and woodland species varied from 5 to 13 mol% (Table 1). Pointleaf manzanita, birchleaf mountain mahogany, Wright silktassel and Pringle manzanita yielded the greatest amounts of olefins. Velvet mesquite and Utah juniper yielded the smallest amounts of olefins and compare closely with the reference feedstocks, fir bark and almond prunings. Outstanding olefin yield was obtained from the reference feedstock guayule cork, which thus far is superior to all other biomass feedstocks tested, including raw guayule and guayule bagasse. This finding was the basis of the effort to identify high olefin-yielding biomass feedstocks and to correlate chemical composition with olefin yield. Rank correlation analysis did not indicate significant correlation between olefin yield and the other variables. A detailed chemical characterization of guayule cork may prove helpful in identifying plant constituents that correlate with high olefin yields in the pyrolysis gas. This in turn could provide a key to discovering high olefin-yielding plants.

We conclude that relatively unproductive chaparral and woodlands are a valuable renewable energy resource from which high-grade liquid fuels can be produced. Side benefits from harvesting these vegetation types would be similar to the main benefits obtained from prescribed burning: range improvement for cattle and wildlife, temporary increases in water yield, and fire hazard reduction. An important difference, however, is that harvesting the biomass for fuel production recovers the stored solar energy, whereas prescribed burning or chemical control methods waste it. Of course, many situations would occur where, because of slope steepness or terrain, harvesting would be impracticable and burning or chemical control would be the method of choice. Conversions from brush to grass in which the brush is killed by means of chemicals offer many years of increased water yield[10,11], but an associated side effect is an increase in the nitrate concentration of the stream water[29]. Harvesting of resprouting brush should not result in the loss of nitrate from the watershed soil to the stream water because the nitrogen cycle would not be broken as it is when the brush is killed.

The problems associated with a programme of harvesting brush to make fuel are being addressed and prospects for their solution are encouraging[30–34]. The design of an operational mobile biomass conversion system that is self-sustaining with respect to energy is essential for range biomass harvesting to be economically feasible. The California mobile pyrolysis unit is an example of such a unit being built to produce low-Btu gas and pyrolytic oil[35]. However, the primary product of this system is a highly oxygenated oil that would require considerable refining to be useful as a transportation fuel. Research on harvesting rotations for maximum sustained yields and fertilization requirements to replace nutrients lost through harvesting will eventually be needed. Of immediate importance is the demonstration of the operational validity of the concept. The research reported here is just a beginning in that it demonstrates that rangeland brush and trees can be converted into high-grade liquid fuels.

This research was partially supported by the US Department of Energy (contract DE-AC02-76CS40202) and the US Department of Agriculture (grants 59-2043-0-2-094-0 and 59-2043-1-6-062-0).

Shallow-water sclerosponges on Jamaican reefs and a criterion for recognition of hurricane deposits

Terence P. Scoffin

Department of Geology, University of Edinburgh, Edinburgh EH9 3JW, UK

Malcolm D. Hendry

Department of Geology, University of West Indies, Mona, Kingston, Jamaica, West Indies

We report here that excavation into the *Acropora palmata* rubble on the reef crest at 4 m water depth on Discovery Bay reefs, Jamaica, revealed the presence of numerous sclerosponges (*Ceratoporella nicholsoni*) living attached directly to the coral branches 1–2 m below the rubble surface. The coral branches excavated were deposited during a storm event (in August 1980) and consequently lack the zoned crusts showing a succession from photophilic (light-loving) to sciaphilic (shade-loving) secondary frame-builders which normally develop during slow steady incremental coral branch accumulation. Thus the nature and sequence of encrustations on coral rubble can indicate the speed of its accumulation.

Before 1980 the shallow reef front (0 to 7 m water depth) of the Discovery Bay west fore-reef consisted predominantly of erect, thick branches of living *A. palmata*[1,2]. In August 1980 large waves generated by hurricane Allen struck these reef and the bulk of the *Acropora* corals were broken and m subsequently died. In July 1983, although there had been sc recovery of *Acropora* corals, there was mainly a loose (estimated at 0.5–2 m thick) of dead *A. palmata* rubble occu ing the shallow reef front and extending leeward into ramp exposed up to 1.5 m above sea level. We excavated a hole a water depth of 4 m, into the loose rubble of the reef cres reveal the internal structure of the accumulation and to n the type and nature of encrusting organisms.

The hole excavated was 3 m in surface diameter and 2 m de and free of sediment less than cobble size. The dead *A. palm* plates extracted ranged from 30 to 150 cm long, 15 to 40 wide and 1 to 10 cm thick. They were stacked at all angles most lay sub-horizontally. A depth zonation of encrusting org isms was clearly evident as the hole was deepened to a de representing a vertical stack of 10–15 *A. palmata* branc Table 1 lists the principal calcareous encrusting organi encountered; most were living at the time of examination. organisms found in each 20 cm depth zone are listed in decr ing abundance and recorded for the upper and lower surf of the *A. palmata* plates. A gradual change from photopl to sciaphilic organisms occurs with depth. The overlapping *palmata* plates shield areas beneath from direct light, altho small gaps in the lattice of branches allowed patches of ph philic organisms to survive in the shafts of light penetra down to a maximum depth of ~80 cm below the rubble surf The crusts of calcareous red algae reached thicknesses of 8 at the surface, but below about 30 cm they were less than 2 thick. Of special interest was the occurrence of numer sclerosponges (*Ceratoporella nicholsoni*), maximum diam 6 mm, average diameter 3 mm, in abundances up to 50 100 cm^2 on the undersurfaces of *A. palmata* branches betw 1 and 2 m below the rubble surface. Almost all the organi listed in Table 1 (except some serpulids and cheilost ectoprocts and the thicker crusts of algae near the surface) v growing directly on the dead *A. palmata* plates; they were overlapping other groups of organisms to form composite cr

Although reef-encrusting organisms have differing rate colonization of new substrates[4,5], 3 years is probably enough for the succession to be complete[5]. Thus, the ver sequence of encrusting organisms observed down the excava is probably a stable community which, if undisturbed, w eventually form crusts of constant composition on the c fragments.

During his study of the calcareous encrusting organism the Recent and Pleistocene reefs of Barbados, Martindale[4] n that *A. palmata* fragments were normally coated by a crust to 10 cm thick) consisting of thick photophilic algal layers to the coral substrate, gradually giving way to thinner lam of sciaphilic algae and foraminiferans, bryozoans and serpu Martindale interpreted this common composite successio being a result of the progressive accumulation of *A. pal* branches, causing a gradual reduction of light, and also a re tion in water circulation and a probable increase in turbi The absence of such a sequence of encrustation on the ru of the Discovery Bay reef crest relates to the instantan deposition of the thick pile of fresh coral branches.

Studies of sclerosponge ecology on Jamaican reefs[6–8] shown that these calcareous sponges can tolerate conditio exceedingly low light intensity and also low levels of nut supply. On Jamaican reefs, *C. nicholsoni* grows out in the down to at least 200 m depth, and is the principal frame-bu between 70 m and 105 m depth[8]. Above 60 m depth it grad becomes more cryptic as the twilight zone recedes further the reef, and above 40 m depth it is almost exclusively ca nicolous. The occurrence of many *C. nicholsoni* skel encrusting the fragments of shallow-water corals indicate existence at some previous time of a deep pile of fine sedim free rubble, through which light could scarcely penetrate water could circulate. The juxtaposition of the sclerospong relatively fresh shallow-water coral fragments indicates tha

pile of rubble accumulated at one depositional event, otherwise a progressive sequence from photophilic to sciaphilic encrusters, would be expected on each coral fragment.

Presently, in sheltered hollows at the surface of the rubble, 10-cm diameter platy corals (*Agaricia agaricites* and *Porites astreoides*) are attached to, and to an extent binding, the *A. palmata* fragments. Unless broken by another major storm, these platy corals, with time, should be preserved as a crudely horizontal platy encrustation on the top of the storm rubble but beneath further 'calm weather' deposits of *A. palmata*, which, no doubt, will soon cover the reef crest. The occurrence of dead encrustations of platy *A. agaricites* at the base of the excavation suggests that we had reached the top of the previous increment of rubble.

Clearly, the depositional histories of cliff or core sections of coral rubble cannot be completely unravelled by studies of the fragments' texture and disposition alone; the nature and sequence of assemblages of encrusting organisms, however, can help to elucidate the rate of supply of coral branches.

We thank Bruce Greenidge for diving assistance and Henry Reiswig for help with animal identifications.

Real and apparent movement nulled

R. L. Gregory & J. P. Harris

Brain and Perception Laboratory, Department of Anatomy, Medical School, University of Bristol, Bristol BS8 1TD, UK

It is a controversial issue whether 'real' movement, seen from the successive stimulation of retinal receptors by a moving image, and 'apparent' (phi) movement, which is produced by stimuli separated in space and time, are transmitted by the same or different neural channels. With this question in mind, we have devised ways to oppose real against opposite-direction apparent movement, to see whether they cancel. Cancelling, especially in a variety of conditions, would be expected for a single but not for separate neural movement channels. As we report here, we find that opposed-direction real and apparent movements will cancel, allowing null measurements to be made.

The simplest method is to rotate a sector disk at constant speed, in, say, a clockwise direction, and illuminate it with two sources—flashes of light at a constant rate, and a continuous light. An electronic stroboscope provides short (1 μs) flashes which are set at a repetition rate to make the sector disk rotate apparently backwards (anticlockwise). The continuous light signals the disk's true (clockwise) rotation as for normal viewing. As the stroboscope flashes are short, the retinal images of the

© 1984 Macmillan Journals Ltd

sectors are essentially stationary for each flash, and so only apparent movement is signalled (anticlockwise) while the continuous light signals clockwise real movement. The question is: is there an intensity ratio of the intermittent and continuous lights at which the opposed real and apparent movements cancel? We find that there is a critical balance of intensities at which systematic movement ceases. At this cancelling null point, all that remains is rapid flicker, or a random jiggle. This is phenomenally similar to what happens when two oppositely moving gratings are viewed superimposed, to cancel two real movements. The finding that opposed real and apparent movements can cancel suggests that they are carried by the same neural channel.

At a lower relative intensity of the continuous light, the apparent movement from the stroboscope dominates and the disk rotates anticlockwise; at higher intensities, it rotates clockwise by real movement. The mean luminance, which is not critical, was in the lower photopic range.

As the disk can have any number of equally spaced sectors, and as the apparent movement occurs at several flash rates, there are many independently controllable parameters, which is exceedingly useful. The real edge velocity of the sectors, given by the rotational velocity of the disk, may be varied independently of the apparent movement, as for any rotational velocity this is given by the number of sectors and the flash rate which are independently variable. For some uses, a band of bars is better than a sector disk, which may have its centre blanked off to restrict the range of velocities along the radii of the sectors. The disks were rotated between 10 and 100 r.p.m., as selected with a stepped ratio gear box driven by a synchronous motor.

It is interesting that with large jumps of the flashed sectors, although apparent movement is maintained cancelling does not occur. The appearance is of two oppositely rotating disks passing through each other, both movements being seen, rather than cancelling. Thus, it seems that only 'short-range' movement[1] will cancel for nulling, and that 'long-range' movement[2], which does not cancel, is signalled by different neural channels. This occurs, for example, in the following conditions: six equally spaced white and six black sectors on an 18-cm disk, rotating at 50 r.p.m., viewed from 2 m. Illumination is: flashes of 1 μs at 8 flashes per s, with a peak luminance of about 10 Cd m^{-2}. This flash rate gives the highest attainable apparent velocity in this situation. The displacements of the signalled sector positions exceed the short-range limit for most of their radii. The added constant light is adjusted for of 2 Cd m^{-2}. These rather critical conditions give simultaneous counter-rotations when the apparent and real movements are balanced instead of nulling. When this is viewed with a fourfold reduction of size at the eye, to bring the flash image jumps within short-range movement, it is seen as nulled rather than as opposed movements.

In the more generally holding conditions for nulling, when colour filters are added, to make, say, the stroboscope flashes blue and the continuous light red, nulling still occurs in spite of colour contrast between the opposed real and apparent movements. Following prolonged fixation of this double-colour nulled movement, no significant after-effect appears, either for white light or when the stationary test pattern is viewed with blue or with red light. These observations provide further evidence that the real and apparent movements are being transmitted by the same neural channel, and that the movement channel is independent of the colour systems. This is confirmed by the observation that, following several minutes' fixation of the rotating disk set up with nulled movement, there is no significant movement after-effect. As would be expected, after-effects are seen in the opposite directions to the adapting real or apparent movements following stimulation either side of the null point.

If the nulled movement is viewed through a defocusing lens to blurr the edges of the moving sectors, the null point remains essentially unchanged. However, when viewed through a neutral density filter (or a pin hole), placed before the eyes so that both illuminations are reduced equally, the null point changes. The real movement from the continuous source is now less effective than the apparent movement from the stroboscope—as now it rotates anticlockwise. This occurs dramatically with a filter of less than half a log unit, and the shift of the null point is greater with higher filter factors. The null can be restored by resetting the luminance ratio, so this effect can readily be measured. It is evidently associated with the eye's adaptation level, and so may indicate its integration time, which increases with dark adaptation; for when a bright light is shone into the eyes, producing light adaptation, the null point shifts in the opposite direction to the shift with the dark filter. This effect is greater for low illuminations of the sector disk, while the dark filter is more effective at higher illuminations, which is to be expected for an adaptation effect. The impairment of real movement may be explained in these terms, for increased integration time must impair temporal resolution of the receptors, which will affect the sequential signalling of real movement as the image runs continuously along the receptors, but can hardly affect the signalling of flashes separated beyond the eye's longest integration time, of a few milliseconds.

Nulling can be achieved without a continuous light—by lengthening the stroboscope flashes. This is done with an electromechanical shutter driven by variable-frequency and duration pulses, and arranged to interrupt a projector illuminating the disk. The real and apparent movements can now be cancelled and nulled with no continuous light, by setting the flash duration so that the real movement which is signalled during each flash equals the opposed apparent movement, given by the repetition rate. Nulling is obtained in this way by adjusting the flash duration around 5–10 ms. The dark filter changes this null point, less than for the short flash plus continuous light. In both cases increase in the eye's integration time with dark adaption impairs continuous movement without impairing the apparent movement, at least for these low flash rates of under 10 Hz.

Repeated texture patterns, in place of the sectors, should allow pattern-signalled movement to be compared with edge signalled movement. It has been shown that apparent movement is lost with isoluminant colour contrast for alternating texture patterns, though not for clearly separate features or objects[3]. The movement nulling technique will be used with isoluminant colour contrast displays, both with repeated texture patterns and with clearly separated sectors or dots, to explore these effects of luminance and colour contrast for textures and individual features, both with the short-range movement, which allows cancelling and nulling, and with long-range movement which, as it does not cancel, seems to work by different neural mechanisms from those of short-range apparent and real movement.

Induction of the ipsilateral retinothalamic projection in *Xenopus laevis* by thyroxine

Sally G. Hoskins* & Paul Grobstein

Departments of Biology and of Pharmacological and Physiological Sciences, The University of Chicago, Chicago, Illinois 60637, USA

Hormones are important in the development of behaviour and there is now abundant evidence that they also affect the morphological development of the nervous system[1–6]. In principle, hormones could act by inducing new patterns of connectivity between widely separated structures in the nervous system or by influencing local connectivity. Most available work documents effects of the latter sort. We present here evidence for

* Present address and address for reprint requests: Department of Biological Sciences, Columbia University, 901 Fairchild Center, New York, New York 10027, USA.

0028–0836/84/080730—04$01.00

the former. Our results indicate that thyroxine, the hormone which causes metamorphosis in the frog *Xenopus laevis*, can induce precociously in a pre-metamorphic tadpole the ipsilateral retinothalamic projection, a retinofugal pathway which normally develops during metamorphosis. Our evidence suggests that the hormone's presence in one eye alone is sufficient to cause axons of some ganglion cells in that eye to grow to targets in the ipsilateral thalamus and to form terminal fields of appropriate morphology. Since the axons of the induced pathway project ipsilaterally, unlike axons in the normal pre-metamorphic tadpole, virtually all of which project contralaterally, our results are also relevant to questions concerning the control of axonal trajectory in the optic chiasm.

The ipsilateral retinothalamic projection in *X. laevis* first appears during metamorphosis[7–9]. In adult frogs, the projection arises primarily from a temporo-ventral subregion of the retina[8,10] and terminates in several nuclei of the rostral and caudal thalamus[11]. We have studied the development of the projection using anterograde transport of horseradish peroxidase (HRP). A complete description of this material is in preparation. Our observations, like those of investigators using ^{3}H-proline[8] and degeneration[7] techniques, show the ipsilateral retinothalamic projection to be a late-developing pathway. Reaction product was either absent or extremely sparse in ipsilateral thalamic terminal zones of tadpoles at stage 54[12], approximately 3.5 weeks old (Fig. 1*b*). In frogs analysed 1 week after the completion of metamorphosis, about 7 weeks old, there was substantial labelling in the ipsilateral terminal fields (Fig. 1*a*).

To determine whether the development of the ipsilateral retinothalamic projection, like other metamorphic changes, depends on thyroxine, we reared tadpoles in 10% Holtfreter's solution and 0.01% propylthiouracil (PTU), beginning at stages 48–50. PTU prevents endogenous production of thyroxine in the thyroid gland by blocking the iodination of tyrosine[13]. PTU-reared tadpoles cease morphological development at stage 54, but remain healthy and continue to increase in size for extended periods[14]. The eyes of PTU-reared animals, like those of stage 54 tadpoles, continue to grow as new cells are added symmetrically to the dorsal and ventral peripheries (Fig. 2). Despite the continuing retinal growth, the ipsilateral projections of PTU-reared stage 54 tadpoles (Fig. 1*c*) remain like those of normal tadpoles at stage 54. When released from PTU, the giant tadpoles complete metamorphosis normally and develop typical ipsilateral retinothalamic projections.

To confirm the thyroxine requirement for development of an ipsilateral projection, we pressure-injected small amounts (3–17 ng) of L-thyroxine in 50 nl Wesson oil into one eye of PTU-reared tadpoles using a calibrated glass micropipette, and continued to house the animals in PTU. Other PTU-reared tadpoles were injected intraocularly with oil alone. Between 3 and 12 weeks after the injection, the optic projection from either the treated or untreated eye was examined by application of HRP to the optic nerve. Some of the tadpoles, particularly those which had received higher doses of thyroxine, advanced slightly in developmental stage during the experimental period, progressing to stages 54–57 (22 cases); other animals, which had received lower doses of thyroxine, or oil alone, remained by all external criteria at the developmental stage characteristic of PTU-reared animals (7 cases).

In 14 of the animals which had advanced slightly in stage, the ipsilateral projections made by the hormone-treated eye were assessed. In 10 of these cases, the optic projection to the ipsilateral thalamus (evaluated by intensity and distribution of label in the thalamic terminal zones as described below) was clearly better developed than that of normal tadpoles at comparable stages (stages 55–57). In several instances, these ipsilateral

Fig. 1 The retinothalamic projection in *X. laevis* 1 week after the conclusion of metamorphosis (*a*), at tadpole stage 54 (*b*) and in a stage 54 tadpole which had been reared in PTU for 25 weeks (*c*). We applied crystals of horseradish peroxidase (HRP) to the central stumps of severed optic nerves. 24–48 h later, the animals were killed and the brains prepared for sectioning. Frozen sections (40 μm) were cut on a sliding microtome, and processed using 0.5% cobalt chloride and 1% diaminobenzidine (DAB) solutions for histochemical demonstration of the HRP reaction product[22]. Photomicrographs are of transverse sections through the rostral thalamus at the level of the nucleus of Bellonci, the largest thalamic terminal field, in animals in which one optic nerve was exposed to HRP. In all three cases, reaction product is present in the optic tract (ot) and in the nucleus of Bellonci (nb; solid arrows) on the contralateral (contra) side of the brain. In the post-metamorphic case, but not in the two tadpoles, reaction product is also evident in the ipsilateral (ipsi) nucleus of Bellonci (nb; open arrows). Scale bars: 100 μm.

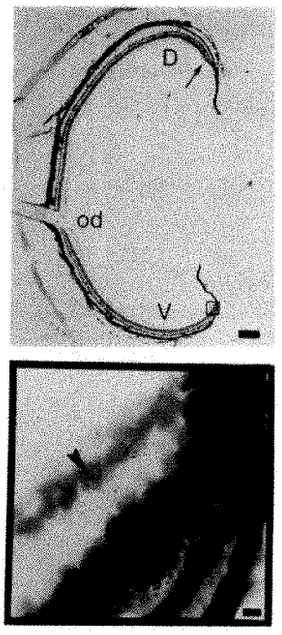

Fig. 2 Retinal growth during PTU-rearing. This PTU-reared tadpole, whose ipsilateral retinothalamic projection is illustrated in Fig. 1*c*, received an intra-abdominal injection of ^{3}H-thymidine (5 μl, specific activity 81.6 Ci mmol^{-1}, NEN), and was subsequently returned to PTU. Eleven weeks later, HRP was applied to one optic nerve of the animal, and its retinal projection was analysed. At this time, the eyes were fixed separately, sectioned at 10 μm and processed for autoradiography. The upper part of the figure is a parasagittal section through one retina, taken at the level of the optic disk (od). Dorsal (D) and ventral (V) are indicated. The lower part of the figure is a higher magnification view of the boxed region of the ventral periphery, showing ^{3}H-thymidine-labelled retinal ganglion cells (arrowhead) peripherally and unlabelled cells centrally. The location of a similar border in the dorsal retina is indicated by the arrow in the upper part of the figure. Scale bars: 100 μm (upper), 10 μm (lower).

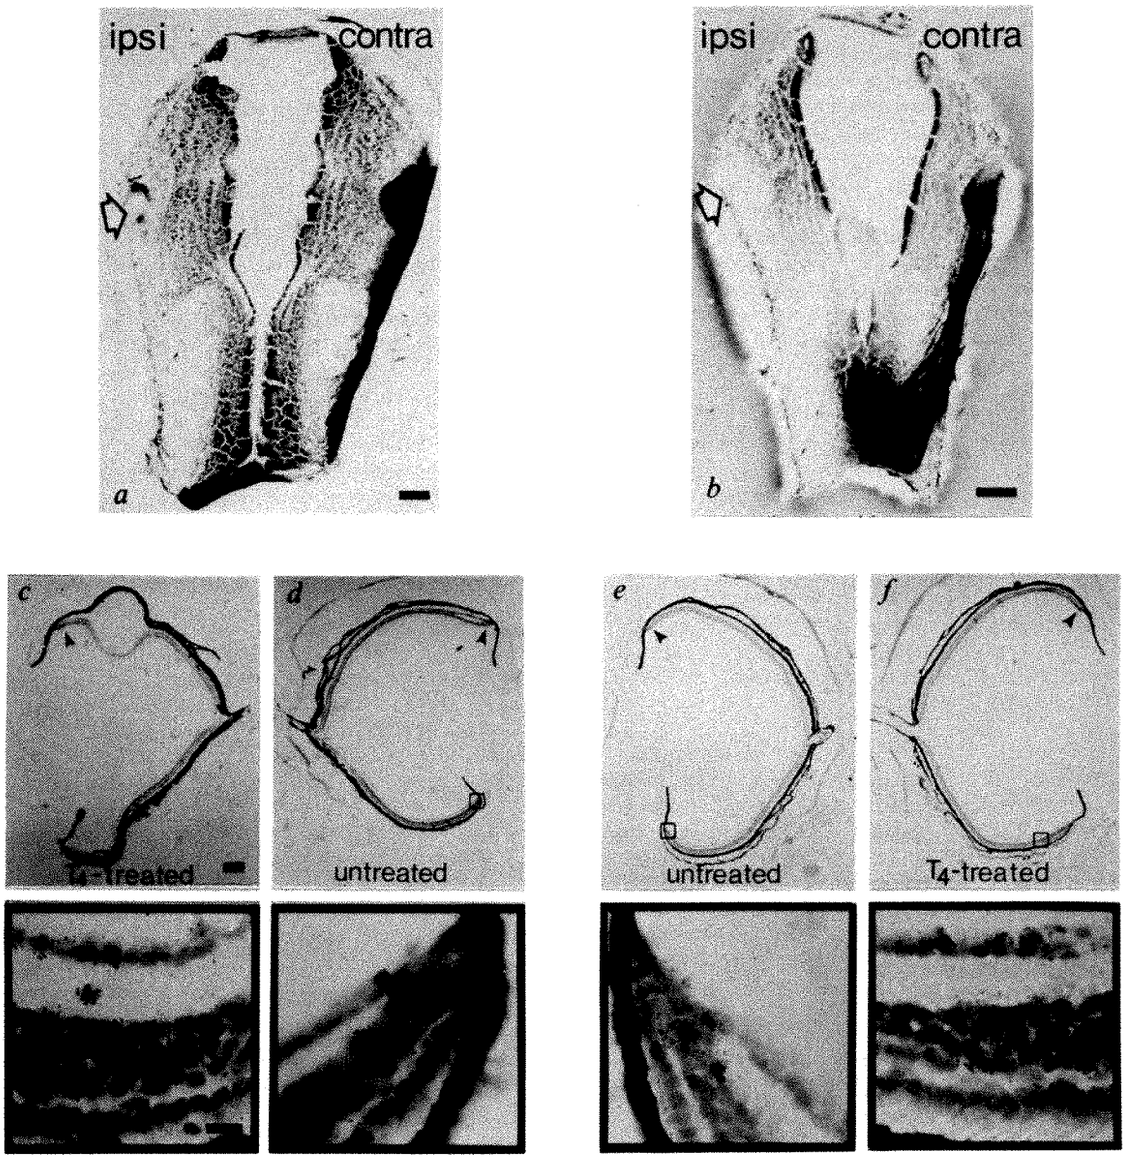

Fig. 3 Effects of injecting thyroxine into one eye of PTU-reared tadpoles. Each animal received an intraocular injection of thyroxine within 24 h of a previous intra-abdominal injection of ^{3}H-thymidine, like that described in the legend to Fig. 2. Photomicrographs are of brain and retinal sections oriented like those of Figs 1 and 2. The sections on the left are from a stage 54 PTU-reared tadpole in which the optic projection from the thyroxine-treated (T_4-treated) left eye was examined following 3 weeks of further rearing in PTU. Sections on the right are from a similar case in which the right eye was thyroxine-treated and the projection from the untreated left eye was examined following 3.5 weeks of further rearing in PTU. The thyroxine-treated left eye developed an ipsilateral projection (open arrow in *a*), while the untreated left eye did not (open arrow in *b*). In both cases, the thyroxine-treated eye added more cells ventrally than dorsally (*c*, *f*), while the untreated eye grew symmetrically (*d*, *e*). As in Fig. 2, arrows and boxes in the low-power retinal sections indicate the locations of ^{3}H-thymidine labelling borders as well as the regions which are shown in the higher magnification views. Scale bars: *a*–*f*, 100 μm; insets, 10 μm.

projections resembled those of postmetamorphic frogs. Four of the tadpoles in this group had ipsilateral projections which were not enhanced, but instead had developed to the extent typical of the animals' morphological stages.

Optic nerve projections from the other, untreated eye were assessed in the remaining eight thyroxine-treated tadpoles which had progressed to stages 55–57. In seven such cases, the ipsilateral projections from the other, untreated eye were those typical of normal untreated tadpoles at stages 55–57. A single stage 56 animal of this group had an enhanced ipsilateral projection. The three tadpoles injected with oil alone showed no change in developmental stage during the experimental period, and the ipsilateral projections from the oil-injected eyes were those characteristic of stage 54 tadpoles. Thus, injections of thyroxine and oil, but not of oil alone, can cause the development of advanced retinal projections to the ipsilateral thalamus. Eyes treated directly with thyroxine were much more likely to produce enhanced projections (10 of 14 cases) than were the untreated eyes of similar tadpoles (1 of 8 cases). These results clearly indicate that exogenous thyroxine can cause development of an ipsilateral projection in tadpoles in which the endogenous production of thyroxine has been prevented[9]. They also suggest that thyroxine acts directly on the eye, since the development of the ipsilateral projection was more advanced in thyroxine-treated than in non-treated eyes, and raise the possibility that a local action of thyroxine may be sufficient to cause development of the projection.

The thyroxine-treated animals which remained at morphological stage 54 throughout the experimental period also produced enhanced projections to the thalamus ipsilateral to the thyroxine-treated eye, providing more direct evidence that local hormone action may be sufficient to induce the projection. We analysed the projection from the thyroxine-treated eye in each of three tadpoles which remained at stage 54 for 3–4 weeks

following injection of 3.75 ng of thyroxine into one eye. Figure 3*a* is a transverse section through the brain of one of these animals, taken at the level of the nucleus of Bellonci (NB), the largest and most heavily innervated terminal field in the ipsilateral thalamus of adult frogs. The distribution of reaction product within this nucleus in the thyroxine-treated case illustrated is similar to that found in the terminal fields of young post-metamorphic animals (Fig. 1*a*), being most dense dorsally and medially with a less densely labelled core. Such a differential distribution of reaction product is not seen in ipsilateral thalamic terminal zones of normal developing tadpoles until stage 60, at which time the overall density of reaction product is still quite low[9]. Similar dense, differentially distributed deposits of reaction product were seen in the ipsilateral NBs of the other two tadpoles in this group. Reaction product was also found in the other usual ipsilateral terminal zones, including the uncinate field, which is not normally innervated until stage 64 (ref. 9).

In a fourth, similarly treated animal which remained at stage 54 following intraocular injection of thyroxine, we analysed the projection from the untreated eye. The projection was typical of that seen in normal tadpoles at stage 54 (Fig. 3*b*). Label was absent in all ipsilateral terminal zones except NB where there was extremely sparse labelling similar to that sometimes seen in normal tadpoles at stage 54 as well as in PTU-reared animals, both untreated and oil-injected.

Beginning at stage 55, the eyes of normally developing *X. laevis* tadpoles undergo a shift in the pattern of cell proliferation, resulting in greatly increased addition of cells to the ventral as compared with the dorsal retinal periphery. This shift can be elicited precociously if thyroxine is injected into the eye of younger tadpoles[15]. The presence or absence of an altered pattern of retinal histogenesis thus provided an additional means of testing whether the action of thyroxine was localized.

The retinas of the thyroxine-treated eyes underwent the expected shift in pattern of histogenesis during the 3.5-week period of the experiment, while those of the untreated eyes did not (Fig. 3*c–f*). Dense concentrations of silver grains mark the cells which underwent their final mitotic division in the presence of the ^{3}H-thymidine label and hence formed the border of the retina at the beginning of the experimental period. In the ventral retina of thyroxine-treated eyes (Fig 3*c*, *f*, and insets), this grain border was displaced centrally as new cells were added during the experimental period. In the dorsal retina, few new cells were added, and the grains remained near the periphery. In the untreated eyes (Fig 3*d*, *e*) of the same tadpoles, in contrast, both dorsal and ventral grain borders remained symmetrically and peripherally located, indicating that the histogenetic pattern of these untreated eyes did not change during the experimental period. The distribution of silver grains in the retinas of such untreated eyes was like that seen in both eyes of PTU-reared, untreated tadpoles.

The production of ipsilateral terminal fields like those of post-metamorphic frogs in the brains of pre-metamorphic tadpoles is a striking example of the hormonal induction of a neuronal pathway. That hormonal induction of the ipsilateral projection was not observed in an earlier, unpublished study (cited in ref. 8) may have been due to the use of triiodothyronine pellets, rather than thyroxine injections. Our evidence that an ipsilateral projection from one eye can be induced in the absence of many if not all of the metamorphic changes normally occurring when the projection develops, also has interesting implications for understanding what controls the patterns of projection made by axons at the optic chiasm.

The induction of an ipsilateral projection from one eye in the absence of a similar projection from the other clearly indicates that interactions between corresponding fibres from the two eyes[16] are not essential for the development of an ipsilateral projection (see also refs 8, 10). The finding also makes it unlikely that the appearance of an ipsilateral projection can be accounted for simply in terms of a critical change at the chiasm since if this were the case enhanced projections should have been seen from both eyes of hormone-treated tadpoles. In general, our findings suggest that the primary change responsible for the development of the ipsilateral projection is a change in the cells of the eye itself. By three criteria (external morphological stage, patterns of retinal histogenesis, and projections of the untreated eye) the action of thyroxine in the animals which remained at stage 54 was restricted to the treated eye.

Both normally and in the experimental situation described here, the development of an ipsilateral projection is correlated with an asymmetric pattern of proliferation of ganglion cells, during which growth occurs primarily in ventral retina[17–19]. Retrograde transport and birthdating studies in normal *X. laevis* indicate that the vast majority of the ipsilaterally-projecting retinal ganglion cells of post-metamorphic frogs lie in retinal regions produced late in development, after the retina has begun to proliferate asymmetrically[20]. The region of the retina which will exhibit enhanced growth is, however, apparently determined much earlier, during embryonic stages. If eye rudiments are rotated or grafted at stages well before stage 54, both the ipsilateral projection[8] and the ventral growth burst[21] are later found to originate from ganglion cells descended from the region previously situated temporoventrally. The ipsilateral projection of normal frogs, then, is formed during metamorphosis by neurones whose eventual fate was determined during embryogenesis. This suggests that the role of thyroxine in the development of the ipsilateral retinothalamic projection is twofold: to produce a new population of ganglion cells, and to permit the expression of a previous determination, one which causes the axons of some of these cells to project ipsilaterally at the optic chiasm. Whether the two events are causally related is a question warranting further investigation.

We thank Drs Héctor Cornejo, R. W. Guillery and Margaret Hollyday for reading and commenting on the manuscript, J. Heberle for help with figures, and Richard Critchlow, Lisa Won and Lee Zwanziger for animal care. This work was supported by NSF BNS 791422.

Evolutionary relationships of ratites and carinates: evidence from ontogeny of the tarsus

C. McGowan

Department of Vertebrate Palaeontology, Royal Ontario Museum, 100 Queen's Park, Toronto, Ontario, Canada M5S 2C6

de Beer[1] proposed that ostriches and their allies, the ratites, are degenerate birds that evolved, neotenously, from carinates (flying birds). Others[2–5] have argued for their primitiveness, but the view that ratites are derived within birds has prevailed[6–8]. The problem is soluble only when avian phylogeny

is understood, and Ostrom[9] makes a strong case for the evolution of birds from theropod dinosaurs. Included in his evidence was the ascending process of the astragalus, a feature first shown by Huxley[2] to be unique to theropods and birds (Fig. 1). Ostrom's critics[10], however, argue that the avian process is not associated with the astragalus, being instead an independent ossification, the pretibial bone[11]. The present ontogenetic study reveals both processes in birds: the ascending process exemplified by ratites and the pretibial bone by carinates. This implies that, since carinates possess the unique pretibial bone, they could not have given rise to the ratites, which are primitive for this feature.

Three series of embryos were obtained (at daily intervals), for the common quail (*Coturnix coturnix*) and for the chicken (*Gallus domesticus*), and these were double stained with Alizarin red and Alcian blue[12]. In addition, developing chickens, emus (*Dromaius novaehollandiae*) and ostriches (*Struthio camelus*) were monitored radiographically. Data were also obtained from X rays, embryos and immature skeletons for the ostrich, emu, kiwi (*Apteryx australis*), cassowary (*Casuarius casuarius*), red-winged tinamou (*Rhynchotis refescens*), brush-land tinamou (*Nothoprocta cinerascens*) and various carinates, specified below. Ontogeny in carinates will be considered first, followed by that of ratites.

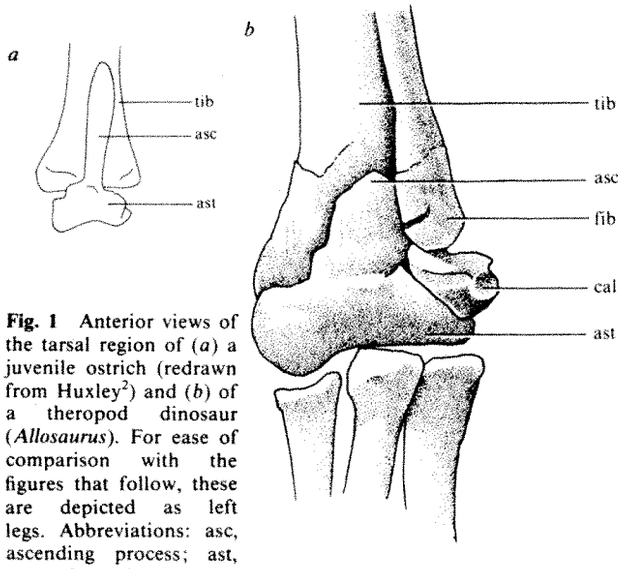

Fig. 1 Anterior views of the tarsal region of (*a*) a juvenile ostrich (redrawn from Huxley[2]) and (*b*) of a theropod dinosaur (*Allosaurus*). For ease of comparison with the figures that follow, these are depicted as left legs. Abbreviations: asc, ascending process; ast, astragalus; cal, calcaneum; fib, fibula; tib, tibia. Note that although the ascending process arises from the astragalus, it lies predominantly on the lateral aspect of the tibia.

Before ossification of the tarsus, which began on day 12 in one of the quails, and day 15 in the chickens, the distal end of the tibia is entirely cartilaginous. There are prominent lateral (calcaneal) and medial (astragalar) condyles, joined proximally, with a cartilaginous spur projecting proximally from the former (Fig. 2*a*; s). This spur, which is the precursor of the pretibial bone, begins ossifying from its tip (Fig. 2*b–d*; pre). Several days later the astragalus and calcaneum begin to ossify. These ossifications appear as small nodules embedded in their respective condyles (Fig. 2*e*; ast, cal). The astragalus is initially about twice as large as the calcaneum in both species. The pretibial bone eventually fuses with the (ossified) calcaneum; in the chicken this occurs some 40 days after hatching (Fig. 2*f*).

Similar relationships between the pretibial bone and calcaneum have been seen in stained embryos of the ring-billed gull (*Larus delawarensis*) and in radiographs of the Adelie penguin (*Pygoscelis adeliae*), common shag (*Phalacrocorax aristotelis*), common starling (*Sturnus vulgaris*), Canada goose (*Branta canadensis*), common eider (*Somateria mollissima*), mallard (*Anas platyrhynchos*), red-headed duck (*Aythya americana*), snow goose (*Chen caerulescens*) and the Mikado pheasant (*Syrmaticus mikado*). Caution is required in drawing conclusions from radiographs alone, but it seems that tarsal development in carinates is uniform.

Huxley[2] was sure that the ascending process of the ostrich was part of the astragalus, but this can be established only if the fate of the calcaneum is known. The youngest ostrich examined, a near-hatching embryo, has a prominent and well-ossified ascending process, expanded distally into a disk of bone occupying about half the width of the distal end of the tibia (Fig. 3*a*; asc, dsc). The disk is separate from, but in contact with, the medial condyle, the latter being largely ossified. The lateral condyle, with which the medial condyle is continuous, is still almost entirely cartilaginous, and is drawn up into a process which appears to be homologous with the precursor of the carinate pretibial bone (Fig. 3*a*; s). However, in marked contrast to carinate ontogeny this process does not ossify later. At this stage the ascending process cannot be said to be part of either astragalus or calcaneum. Radiographs of two 5-week-old juveniles show that the ascending process becomes contiguous with the astragalus, the identity of the astragalus being confirmed by the appearance of a small calcaneum lying lateral to it (Fig. 3*b*; cal). By the 11th week the calcaneum has fused with the astragalus (Fig. 3*c*). Three emu chicks, X-rayed weekly from 4 to 12 weeks after hatching, each showed a putative astragalus,

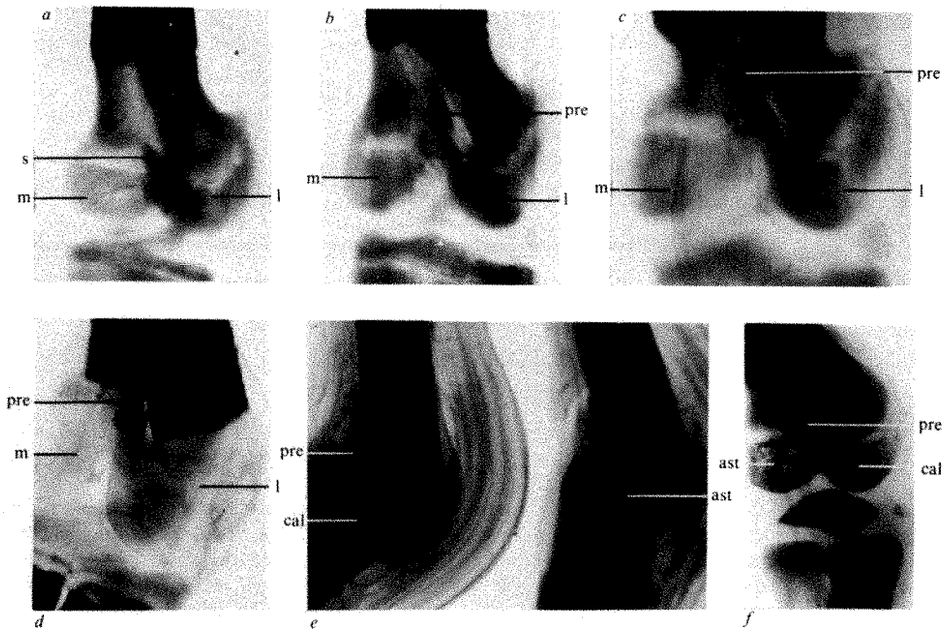

Fig. 2 Development of the carinate tarsus. Left leg depicted, unless otherwise stated. *a*, *b*, 12-day-old quail embryos, anterolateral views; *c*, 14-day-old quail embryo, anterolateral view; *d*, 19-day-old chicken, anterolateral view; *e*, 16-day-old quail, lateral view of left leg and medial view of right leg; *f*, sub-adult chicken, 40 days after hatching, anterolateral view. Abbreviations as in Fig. 1 with additions: l, lateral condyle; m, medial condyle; pre, pretibial bones; s, cartilaginous spur.

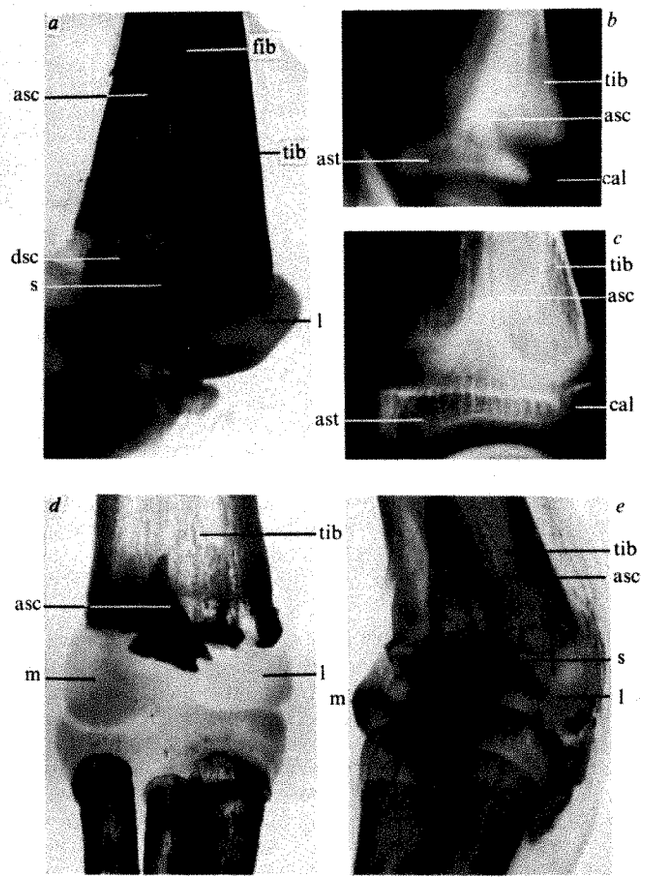

Fig. 3 Development of the ratite and tinamou tarsus. Left legs depicted. *a–c*, Ostrich; *d*, *e*, red-winged tinamou. *a*, Ostrich embryo shortly before hatching, anterolateral view; *b*, *c*, X rays of 5-week-old and 11-week-old juvenile ostriches, anterior views; *d*, late tinamou embryo, shortly before hatching, anterior view; *e*, hatchling tinamou, approximately 1 week old, anterolateral view. Abbreviations as in Fig. 2, with addition: dsc, distal disk of ascending process.

with an ascending process, but no evidence of an ossified calcaneum. However, in one of four stained, near-hatching embryos, there is a small ossified calcaneum, confirming the identity of the astragalus. Radiographs of six embryonic and five subadult kiwis show a prominent ascending process but, as in the emu X rays, no evidence of an ossifed calcaneum. Parker[13], however, showed that the diminutive calcaneum had become incorporated into the astragalus, with its associated ascending process, prior to ossification. Evidence for the cassowary and rhea is presently incomplete, but radiographs show a putative astragalus with a prominent ascending process, as in the other ratites. Holmgren's[14] avian studies focusing on the earlier (precartilaginous) stages of development, are of limited interest here; however, he drew the erroneous conclusion that ankle development in the ostrich scarcely differed from that in the chicken, gull and duck.

Tinamous possess a mosaic of ratite and carinate features and it is therefore important to consider their tarsus. Examination of late embryos of the red-winged tinamou reveals a prominent bony ascending process lying midway between the (conjoined) lateral and medial condyles (Fig. 3*d*; asc). There are no other ossifications at this stage. In a week-old hatchling a prominent spur can be seen arising from the lateral condyle, similar to that seen in the ostrich (Fig. 3*e*; s). There is no evidence of a calcaneal ossification, but there is a small astragalus. The ascending process of the red-winged tinamou is, therefore, not an ossification of the spur from the lateral condyle, and so is not homologous with the pretibial bone of carinates but corresponds instead to the ratite condition.

There are therefore two different tarsal conditions in birds. Carinates have a pretibial bone, an ossification of a cartilaginous spur which fuses with the calcaneum. This is a synapomorphy for carinates, implying that they did not give rise to the ratites, contrary to de Beer's[1] hypothesis. Ratites (including tinamous) have an ascending process, an ossification which fuses with the astragalus, as in theropods[15]. The ratite tarsus is, therefore, in the primitive condition. Indeed, most of the features that distinguish ratites from carinates are now considered to be primitive rather than derived[3–5,16]. They include the palaeognathous palate[17,18], a feature that has been used as evidence for neoteny[19], albeit on slender evidence[6]. Ratites should therefore be viewed as primitive rather than as derived birds. This does not imply that ratites descended directly from a stage in bird ancestry before the power of flight had been acquired, only that their ancestral stock was more primitive than carinates, a point made elsewhere[16,20].

I thank the Metropolitan Toronto Zoo, especially K. Mehren and E. Smith; for supplying specimens, C. Edwards for alizarin preparations, C. Gilmore for histological preparations, J. Molecular genetic evidence for early evolutionary origin of budding peptidoglycan-less eubacteria

Recent studies on the cell wall composition of budding, non-prosthecate bacteria have shown that representatives of the genera *Planctomyces* and *Pasteuria* (*sensu* Staley, 1973) lack the peptidoglycan moiety[1], which is the characteristic feature of eubacterial cell walls[2,3], but possess an as yet unidentified protein sheet instead; in this respect *Planctomyces* and *Pasteuria* strains resemble certain archaebacteria more than eubacteria[3,4]. To determine their phylogenetic positions, the 16S ribosomal RNAs of three budding, peptidoglycan-less strains with and without stalks were subjected to partial

0028-0836/84/080735—03$01.00

© 1984 Macmillan Journals Ltd

sequence analyses. As we report here, the comparison of data with those obtained from about 320 eubacterial and 40 archaebacterial strains revealed that the strains investigated are not members of the archaebacterial kingdom but represent an ancient line of descent of the eubacterial kingdom. Furthermore the diphtheria toxin reaction[5] of *Planctomyces* and *Pasteuria* shows that they behave like eubacteria.

The three strains of budding, non-prosthecate bacteria investigated share the main characteristics of members of the *Planctomyces–Blastocaulis* group of bacteria[6]. They were isolated from brackish surface water of the Kiel Fjord, Baltic Sea[1]. Strain IFAM 1317 (IFAM = Institut für Allgemeine Mikrobiologie, University of Kiel) and strain IFAM 1310 resemble *Planctomyces maris*[7] and *Pasteuria ramosa* (*sensu* Staley, 1973), respectively, while strain IFAM 1319 shows no distinct similarity to any of the described species of this group. Cultivation of these organisms followed described methods[1]. Isolation of 16S rRNA[8–10] and sequence analysis[10–13] were done as described. Similarity coefficients, S_{AB} values[14], were calculated using a CDC computer.

Table 1 shows the similarity coefficients, calculated from the 16S rRNA oligonucleotide catalogues of the three strains investigated (not shown) and more than 350 bacterial reference strains. The S_{AB} values show strains IFAM 1310 and IFAM 1319 to be rather closely related (0.70), while they show less rRNA sequence homology with the *Planctomyces maris*-like strain IFAM 1317 (0.30 and 0.32, respectively). The degree of relatedness found between these three organisms and representatives of the various lines of descent of the eubacterial kingdom indicates that they are significantly more remote (with S_{AB} values ranging between 0.06 and 0.21, with an average value of 0.15), while almost no relationship can be detected to members of the archaebacterial kingdom (0.04–0.12, average 0.10). The range of the latter S_{AB} values is of the same order of magnitude as that found between representatives of the eubacterial and archaebacterial kingdoms (0.06–0.14)[15]. The lack of relationship between archaebacteria and budding, non-prosthecate and peptidoglycan-less bacteria agrees with results of the diphtheria-toxin reaction, recently used to distinguish archaebacteria and eubacteria[5,16] (Table 2). Cell supernatants of strains IFAM 1310 and IFAM 1317 do not contain proteins that served as substrate for the diphtheria toxin; in this negative reaction they resemble eubacteria[5,16]. Archaebacteria and eukaryotes, on the other hand, serving as a control, give significant diphtheria toxin-dependent protein labelling.

While it is clear that *Planctomyces* and relatives are not related to archaebacteria, the rRNA analyses do not indicate their status as a third line of descent of prokaryotes independent of those of archaebacteria and eubacteria. Our data indicate that the peptidoglycan-less bacteria have to be considered as eubacteria, with average S_{AB} values between *Planctomyces* and relatives and the eubacteria, being lower (0.15) than those found in the various lines of descent of eubacteria (0.22)[15,17]. The exact phylogenetic position, however, cannot yet be determined, since it is not known whether the 16S rRNA cistrons of *Planctomyces*- and *Pasteuria*-like strains have evolved at the same rate as those of eubacteria, which, with certain exceptions[18,19], appear isochronic. If one assumes that the evolutionary rate of the strains investigated differs from that of the majority of eubacteria, the lack of peptidoglycan and of certain universal oligonucleotides present in the 16S rRNA of isochronically evolving eubacteria[19,20] (that is, CACAAG, CUAACG, AAUACG, UUCCCG, AUACCCUG, AUUCCUACG) can be taken as positive evidence for this theory. In this case, the phylogenetic position of *Planctomyces* and relatives is within the main radiation of eubacterial species, either representing an individual line of descent or specifically related to members of one of its lines (as, for example, the fast-evolving mycoplasmas and relatives were found to be related to certain strains of *Clostridium*[18]).

However, a degenerate evolution of the budding, non-prosthecate and peptidoglycan-less eubacteria is not proven. The possibility therefore remains that these organisms represent the descendants of an ancient group of eubacteria that branched off immediately after the divergence of the 'ur-eubacteria' from

Table 2 Diphtheria toxin reaction with cell supernatants from budding, peptidoglycan-less eubacteria (I), peptidoglycan-containing eubacteria (II), archaebacteria (III) and eukaryotes (IV)

		TCA-precipitable radioactivity (pmol NAD per mg supernatant protein)

the universal common ancestor of extant life, the 'progenote'[21], and before the main radiation of eubacterial lines of descent[17,19]. According to this theory the lack of certain universal oligonucleotides in the 16S rRNA catalogues implies not a loss due to high mutation rate, but rather that these universal eubacterial oligonucleotides evolved later in the evolution of eubacteria, after the ancestor of *Planctomyces* and relatives had already branched off. The eubacterial universal oligonucleotides missing in the catalogues of *Planctomyces* and relatives are also missing in archaebacteria which diverged even earlier than did the budding, peptidoglycan-less eubacteria. Likewise, the lack of the peptidoglycan moiety reflects a primitive state of eubacterial cell walls, with the 'invention' of peptidoglycan following at a later stage in the evolution of eubacteria.

This work was supported by a research grant from the Deutsche Forschungsgemeinschaft. We thank C. R. Woese for providing us with unpublished data.

Possible artefactual basis for apparent bacterial growth at 250 °C

Jonathan D. Trent, Roger A. Chastain & A. Aristides Yayanos

Scripps Institution of Oceanography, University of California, San Diego, La Jolla, California 92093, USA

Baross and Deming[1] reported that thermophilic marine bacteria isolated from the vicinity of a submarine hot-spring grow at temperatures up to at least 250 °C. They did not, however, conduct the appropriate control experiments to eliminate the possibilities of chemical artefacts or contamination. Here, in experiments using the same growth medium, the same temperature and pressure apparatus[2] and the same sampling and analytical procedures, we report results nearly identical to theirs. We conclude that their evidence indicating bacterial growth at 250 °C may be due to artefacts produced in the medium and to contaminants introduced during sample processing.

The 'black smoker' hydrothermal vent, discovered at a depth of 2,650 m at 21° N on the East Pacific Rise, releases 350 °C water into the ocean[3]. Water remains liquid at this temperature due to hydrostatic pressure. It has been suggested that the absence of liquid water, rather than high temperature *per se*, limits bacterial growth[1]. This idea has been logically extended to predict that extreme thermophiles could inhabit submarine hydrothermal vents[4].

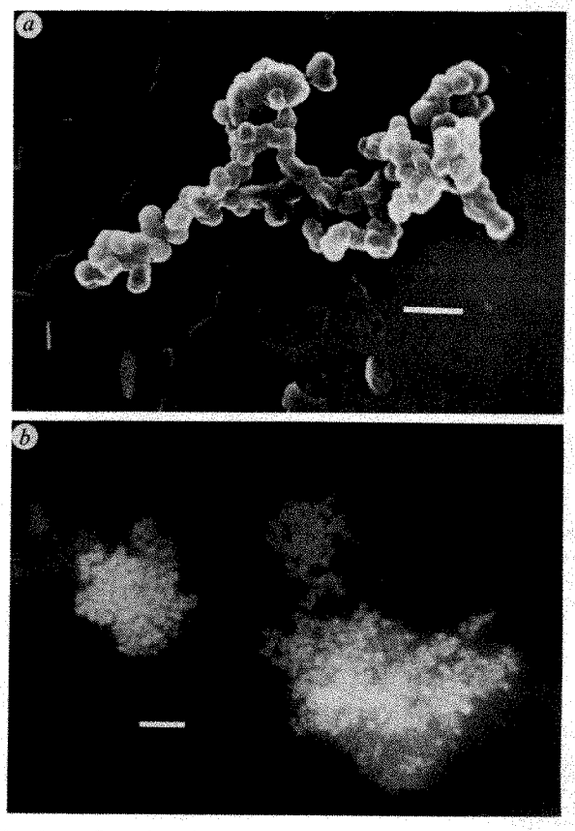

Fig. 1 *a*, Scanning electron micrograph of particles resembling bacteria from uninoculated medium after 4 h at 250 °C and 265 atm pressure. Scale bar, 1 μm. *b*, These particles are not DAPI-stained but autofluoresce, giving them some resemblance to DAPI-stained bacteria. Scale bar, 3 μm.
Methods: Experiments were conducted in a high-temperature and high-pressure apparatus[2]. The temperature of this system at pressure is monitored by a thermocouple and a gauge thermometer inserted into the wall of the pressure chamber. The temperature inside the chamber was 238 ± 2 °C when the wall temperature read 249 ± 2 °C. Samples were taken before the medium was heated, when it reached maximum temperature, and then at approximately 1h intervals for 5–6 h. Samples were fixed with 2% E.M.-grade glutaraldehyde and stored at 4 °C until analysed. For epifluorescent microscopy, glutaraldehyde-fixed samples were transferred in duplicate to sterile tubes. One subsample was untreated and used to measure autofluorescence and the other was stained with DAPI at a final concentration of 0.02 μg ml^{-1} for 1–3 h. Between 0.01 and 1.0 ml of sample was transferred into 5 ml of diluent (synthetic seawater with 0.25% formalin and 0.05% azide) and filtered onto 0.2-μm Nucleopore filters stained with Irgalan black. Over 200 objects were counted for each sample.

Baross and Deming's experiments were conducted using apparatus in this laboratory and their samples were analysed at Oregon State University. Their strongest evidence for the existence of 'black smoker' bacteria was based on growth curves, protein concentrations and transmission electron micrographs. Experiments were done at 265 atm pressure and 150, 200, 250 and 300° Celsius. An uninoculated control was done at 200 °C but no data are given. Controls were not done at any other temperature. Only at 250 °C is there a reasonable correlation between increases in cell concentrations and protein, and transmission electron micrographs of cells were from that temperature.

We requested a culture from Baross to verify their results independently. Although we did not receive the culture, we conducted experiments with uninoculated media and with media inoculated with a non-thermophilic marine bacterium, *Vibrio harveyi*. These experiments were designed to look for artefacts arising in the medium itself or in medium supplemented with cellular material.

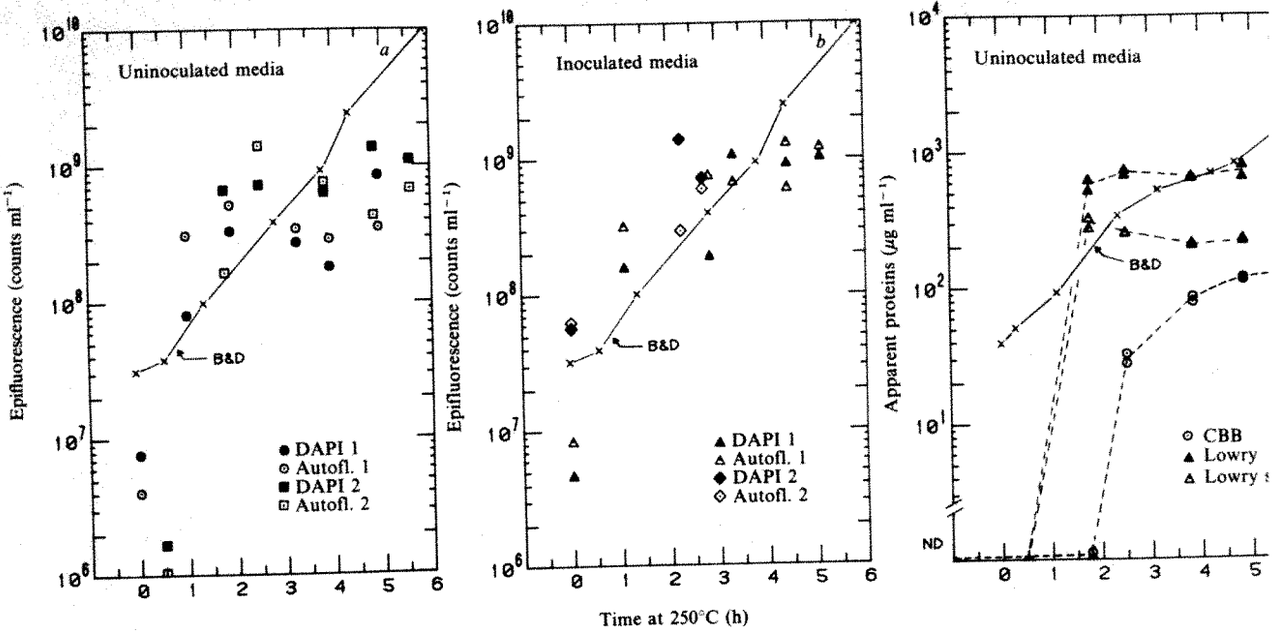

Fig. 2 *a*, In both experiments 1 and 2, the addition of DAPI did not increase counts above autofluorescence, indicating that DAPI stai did not occur. The solid curve labelled B & D shows the data reported by Baross and Deming. *b*, Experiments in which bacteria were ad to media gave the same results as uninoculated media. The solid curve labelled B & D shows Baross and Deming's data. *c*, Before hea there is no measurable protein in the media using either the Coomassie brilliant blue (CBB) or the Folin–Lowry (Lowry) techniques. A heating to 250 °C for 1 or 2 h, colour develops, suggesting the presence of proteins. Part of the absorption in the Lowry technique is du the presence of a precipitate; centrifuging samples to remove turbidity decreases absorption (Lowry sp.). The solid curve labelled B & from the original paper by Baross and Deming[1]. 'ND' signifies not detected.

Methods: The medium is described as 'minimal salts' (MS) supplemented with: *a*, 0.03% $(NH_4)_2SO_4$; *b*, 0.001% $Ca(NO_3)_2$; *c*, 0.0(Bacto-yeast extract (Difco); *d*, 0.3% HEPES buffer (Sigma); *e*, 0.2% $Na_2S_2O_3 \cdot 5H_2O$; *f*, 0.02% $MnSO_4 \cdot H_2O$; *g*, 0.001% $FeSO_4 \cdot 7H_2C$ 0.05%Na_2HPO_4; *i*, 0.5% $NaHCO_3$; *j*, trace element mix[12]. Stock media consisted of seven solutions: minimal salts plus *a*–*d*, made as solution at 2 times concentration; *e*–*i*, made as five separate solutions at 10 times concentrations; and *j*, made at the concentration at w it is used. All stock media were made with Nanopure water, stored at room temperature and except for *g*, which was filter sterilized, all sterilized by autoclaving. For inoculated controls, 1 ml of stationary phase *V. harveyi* ($\sim 5 \times 10^8$ cells) was centrifuged, rinsed with 1 n medium, re-centrifuged and suspended in the experimental medium. Protein concentrations in glutaraldehyde-fixed samples were meas using the methods reported by Baross and Deming[1]. Aliquots of 0.5 ml were centrifuged at 13,000*g* for 1.5 min at 25 °C. The supern was aspirated and the pellet was precipitated by addition of 0.5 ml of cold 5% TCA for 1 h on ice. The sample was repelleted by centrifug at 13,000*g*, 1 min at 4 °C; the precipitate was washed with cold 5% TCA as above, and pelleted a third time. The final pellet was solubi with 200 μl of 1 M NaOH, and the *p*H adjusted to ~7 with 200 μl of HCl. The data reported in *c* are from the above method but varia on this method included direct protein measurements on unprocessed samples, TCA precipitation before initial centrifugation and no addition of HCl to adjust *p*H. All procedures gave some colour development with heated media, suggesting that the Folin–Lowry an Coomassie techniques should be used with caution, or that other protein assays should be used to evaluate these samples.

Our results showed no significant differences between uninoculated media and *V. harveyi* inoculated media at high temperature and pressure. A flocculent, white precipitate due to the mixing of manganese sulphate, sodium phosphate and sodium bicarbonate was present in the unheated media. This precipitate contained no epifluorescent particles above background and no measurable proteins. The amount of precipitate in the media decreased during heating and changed consistency from an amorphous floc to distinct micrometre-sized spheres (Fig. 1*a*). These spheres resembled bacteria in size and shape and were seen alone or in clumps (Fig. 1*a*, *b*).

For their growth curves, Baross and Deming measured changes in particles stainable with 4′,6′-diamidino-2-phenylindole (DAPI), a DNA-specific stain routinely used to count bacteria[5]. The spheres we observed in heated media were autofluorescent and were not DAPI stained (Fig. 2*a*, *b*). Baross and Deming report observations of autofluorescence in their samples but they attribute it to methanogenic bacteria.

In our experiments the concentration of spheres increased for the first 2 or 3 h then stabilized at $\sim 10^9$ per ml. In Baross and Deming's experiment at 250 °C, particles reached a concentration of 10^{10} per ml (Fig. 2*a*, *b*, curve B & D). We think this difference between our 'controls' and their experiment is not significant given the variability we observed due to mixing, sampling and counting.

Samples were processed for protein using the procedures described by Baross and Deming. Protein concentrations were measured using the Folin–Lowry and the Coomassie b blue techniques[6]. We found that heated media change time and gave positive readings in both protein assays (F A number of non-protein substances have been found t fere with the Folin–Lowry[7] and Coomassie brilliant blue[8] We do not know the reason for the positive protein reac our heated media.

Apparent protein concentration, measured with the technique, reached a plateau shortly after the media r maximum temperature. Subtracting our apparent protei trol' values from Baross and Deming's 250 °C 'bacteria' (Fig. 2*c*, curve B & D), leaves only one data point background at the end of their experiment. As in the epifluorescent microscopy, the difference between our d theirs may be attributed to differences in sampling pro and processing. For example, if precipitates are not r by centrifugation or otherwise corrected for, apparent concentrations are significantly higher (compare Lov Lowry sp., Fig. 2*c*).

Baross and Deming present transmission electron graphs of bacterial cells kept at 250 °C for 7 h. We u techniques to prepare samples for transmission electror scopy. Both methods resulted in satisfactory fixation of *veyi* in the unheated medium (Fig. 3*a*). In heated me first method revealed the formation of micrometre-sized that with few exceptions did not resemble cells (Fig. 3*b* the second method (A. Soeldner, personal commun

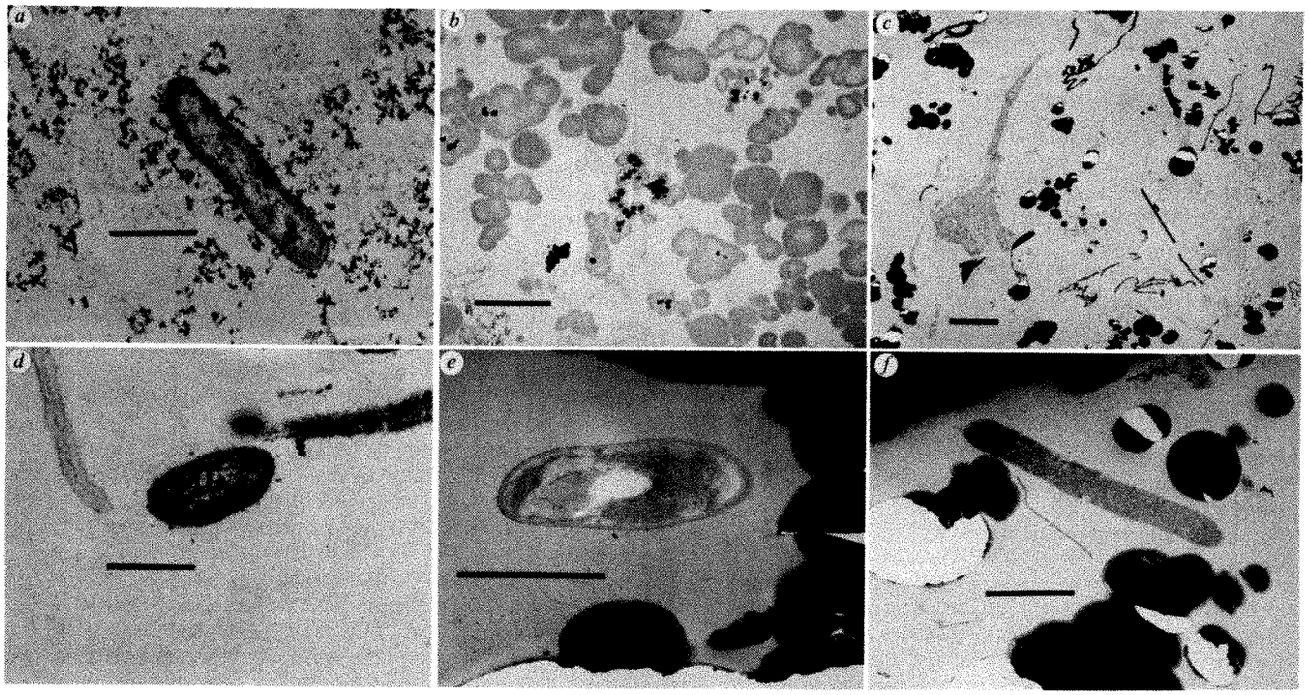

Fig. 3 *a*, A transmission electron micrograph of unheated medium inoculated with the non-thermophilic bacterium *V. harveyi*. The cell is surrounded by the precipitate present in the starting medium. Scale bar, 1 μm. *b*, After heating to 250 °C at 265 atm pressure, all *V. harveyi* cells disappeared. Using an embedding technique with filtered agar, only micrometre-sized spheres were found in a sample after 4 h at temperature and pressure. Scale bar, 3 μm. *c*, The same sample shown in *b* processed using the embedding procedure used by Baross and Deming, shows the same spheres more darkly stained and a variety of other objects including cells. Scale bar, 3 μm. *d–f*, Examples of cells and cell-like objects found in thin sections from uninoculated media heated to 250 °C for 4 h and processed using the same transmission electron microscopic procedure used by Baross and Deming. Scale bars: *d*, 0.5 μm; *e*, *f*, 1 μm.

Methods: Immediately after sampling, specimens were fixed for electron microscopy by adding glutaraldehyde to a final concentration of 2%. Fixed material was washed with 0.2 M cacodylate buffer (*p*H 7.8) and postfixed with 1% OsO_4 in buffer. In one procedure fixed samples were embedded in 0.22 μm filtered 2% Nobel agar (Difco) in buffer and dehydrated in ethanol. In the other procedure samples were embedded in unfiltered Ionagar (Oxoid no. 2) in buffer, dehydrated in acetone and stained with uranyl acetate before final dehydration (70% step). All specimens were infiltrated with Spurr resin. Silver-grey thin sections were post-stained with 4% uranyl acetate and 0.1% lead citrate.

which was used by Baross and Deming, we found many objects that resembled cells (Fig. 3*c–f*). The critical difference between the two methods was the use of 0.2-μm filtered embedding agar in the first method and the use of unfiltered agar in the other method. It thus seems likely that the cells seen by Baross and Deming in samples incubated at 250 °C and 265 atm did not survive exposure to these conditions but were contaminants added to the samples after they were cooled and decompressed.

The production of methane, hydrogen and carbon monoxide and the presence of protein amino acids are also presented as evidence for black smoker bacteria. Gas production in Baross and Deming's experiments was measured after 3 h at 300 °C. No gas data are reported from 250 °C. Their uninoculated media control was done at 200 °C rather than 300 °C and reportedly did not produce gases. We did not analyse our 'control' samples for gas production.

We determined protein amino acids on three of our samples using Baross and Deming's procedures. One sample was from uninoculated and unheated medium, a second sample was from medium uninoculated and heated for 4 h at 250 °C, and a third sample was from medium inoculated with *V. harveyi* and heated for 4.5 h at 250 °C. These samples were analysed by the Amino Acid Dating Laboratory at Scripps Institution of Oceanography. A total of 200 nmol ml^{-1} (predominantly serine, glutamic acid, glycine and aspartic acid) was measured in the trichloroacetic acid (TCA)-precipitable fraction of our unheated, uninoculated sample. Other amino acids were present at the detection limits of the analytical facility (~1 nm). In samples of both the uninoculated and inoculated media that were heated to 250 °C, total amino acids in the TCA-precipitable fraction were 120 and 80 nmol ml^{-1}, respectively, with the same four amino acids found in unheated samples predominating. We think the levels of amino acids measured in our control samples were due to contamination in the pressure apparatus or from reagents used in sample processing.

Amino acid data reported in Baross and Deming's Table 1 are fractions (addition of their data totals 1.0002). Their caption states that concentrations of amino acids can be derived from their total colorimetrically determined protein data minus 25% for unknown peaks. Since we have shown that their colorimetric protein determinations are suspect, it is not clear what concentrations of amino acids are actually present in their samples, or if they are greater than the levels of contamination we found in uninoculated media. They report a number of amino acids, such as serine and threonine, which are known to be unstable at elevated temperatures[9]. Contamination is a significant problem when measuring trace amounts of amino acids[10,11]. Since Baross and Deming's amino acid data are based on a single determination, without controls, we do not consider them good evidence for the existence of black smoker bacteria.

In Baross and Deming's experiments only their results from 250 °C were suggestive of bacterial growth. There were no controls done at this temperature and thus no way to eliminate artefacts. The experiments reported here indicate that artefacts are produced in media heated to 250 °C at 265 atm pressure in the experimental system used[2]. These artefacts cast some serious doubts on their reported growth curves and protein data. Contamination and abiotic micrometre-sized spheres could account for the micrographs of 'cells' Baross and Deming reported from their 250 °C samples. Data on gas production and amino acids are not presented in sufficient detail to be seriously considered supporting evidence for the existence of black smoker bacteria.

This work was supported by NSF grant OCE-8208419 and a contract from Sandia National Laboratories. We thank R. Van Boxtel, A. S. Dietz, P. A. Farnsworth, J. A. Baross and A. Soeldner for technical assistance, J. L. Bada and D. Darling

for amino acid analysis, and S. L. Miller, H. Craig and K. H. Nealson for reviewing our manuscript.

The conclusion of Trent *et al.* that no bacterial growth occurred in our experiments[1] is not tenable because of crucial differences between the results of our work and theirs, and because of additional data not addressed by these authors. If the scores of morphologically diverse bacteria we observed in thin sections of a 250 °C sample were contaminants, they would have appeared in the 300 °C sample also reported[1], since both samples were processed simultaneously using the same reagents. Such was not the case. Recent amino acid analyses[2] from our original experiments[1] indicate that at 250 °C the total amino acid content of particulate protein increased from 1.6 to 145 $\mu g\ ml^{-1}$ in 5.4 h, a doubling time of approximately 1 h. The same doubling time was calculated for concentrations of each of the 15 amino acids (including serine and threonine) detected by the standard methods we used[1,2]. We continue to work with the original culture of black smoker bacteria, as well as the viable culture recovered from the titanium syringe upon termination of the 250 °C experiment, and one of us will dive with the French in March 1984 to search for similar bacteria in unexplored smokers at 13° N.

Role of an upstream regulatory element in leucine repression of the *Saccharomyces cerevisiae leu2* gene

Alfonso Martinez-Arias*‡, H. Joseph Yost† & Malcolm J. Casadaban*†

* Department of Biophysics and Theoretical Biology, and
† Committee on Genetics, University of Chicago, Chicago, Illinois 60637, USA

The expression of a number of eukaryotic genes has been shown to involve at least two sequences located upstream of the actual transcription unit[1–7]: one of these sequences, centred on a widely conserved TATAAT sequence, is thought to be involved in determining the precise site of initiation of transcription[1,8]; the other has a gene-specific sequence, can function at a variable distance upstream of the initiation site[3,9], and is involved in the regulation of transcription[3,4,7,10]. By constructing β-galactosidase gene fusions, to facilitate measuring gene expression *in vivo*, we have now defined a *cis*-acting regulatory element of the *Saccharomyces cerevisiae leu2* gene. This element is located within a 280 base pair (bp) fragment which occurs 125 bp upstream of the *leu2* translation initiation codon and which contains a short G+C-rich palindromic sequence. A fragment of the *Escherichia coli* transposable element Tn*9* which contains a similar palindromic sequence can functionally replace the natural *leu2* regulatory element. Our results are contrary to previous speculations that the *leu2* gene is regulated by an attenuation mechanism[11,12].

Biochemical studies of the *leu2* locus of *S. cerevisiae*, which encodes β-isopropylmalate dehydrogenase, an enzyme of the leucine biosynthetic pathway, have indicated that enzymatic activity is repressed when cells are grown in the presence of leucine and threonine[13]. DNA sequence analysis of the region upstream of *leu2*[12] has revealed the complex arrangement (Fig. 1) of a Ty*1* transposable element, a leucyl tRNA gene and an open reading frame with the potential for encoding a 24 amino acid polypeptide containing 6 leucine residues. This led to speculation about the regulatory mechanisms that may be operating at this locus[11,12]. To investigate further the nature of this regulation an *Xho*I–*Bst*EII fragment, which extends from the Ty*1* δ element to the 13th *leu2* codon, was fused *in vitro* to the *E. coli* β-galactosidase gene on the vector pMC1790[14,15], as described in Fig. 1. Comparable fusions to the β-galactosidase gene have been used to study the regulated expression of several other genes in yeast[16–18]. The resulting fusion plasmid pMC1876 expresses a level of β-galactosidase in transformed[19] yeast cells that is repressed fivefold when the cells are grown in the presence of 1 mM leucine and 1 mM threonine (Table 1).

The *leu2* control region in the fusion plasmid was dissected as illustrated in Fig. 2 and assayed as summarized in Tables 1 and 2. A deletion from the upstream side extending to the middle of the $tRNA_3^{leu}$ gene sequence (Δ1) results in a small increase in β-galactosidase expression but no qualitative changes in the pattern of regulation. Total removal of $tRNA_3^{leu}$ gene sequences in this region (Δ8) leads to a further increase in β-galactosidase expression. This suggests that the tRNA gene is not directly involved in the regulation of this locus, although its presence does exert a small effect on *leu2* expression, perhaps due to steric interactions between factors bound to these two closely linked genes[20]. Removal of sequences up to the *Hin*cII site located 125 bp upstream of the *leu2* translation initiation codon (Δ2) results in a 100-fold decrease in β-galactosidase activity and the loss of leucine-specific regulation. This indicates that regions important for regulation exist between the tRNA gene and the *Hin*cII site. Moreover, as the Δ2 deletion does not remove the major transcription initiation site (A. Andreadis and P. Schimmel, personal communication) the regulation of this locus presumably takes place primarily at the level of transcription.

To explore this further, we exchanged the DNA fragment between the *Hin*cII site and the *Bst*EII site in Δ1 with a 250 bp piece of DNA containing the transcription and translation initiation regions from the *cyc1* gene of *S. cerevisiae* fused to the β-galactosidase gene[17,21]. When this fusion, which has a hybrid promoter (HYΔ1), was assayed in yeast, β-galactosidase activity was regulated by leucine and threonine (Table 2). This fusion does not respond to other amino acids in the culture medium nor to catabolite repression, which is the normal regulatory pattern of the *cyc1* gene. This indicates that the *leu2* regulatory element is located upstream of the *Hin*cII site and well before the *leu2* coding region. It is interesting, however, that the levels of β-galactosidase expressed by HYΔ1 are lower than those of the wild-type *leu2* promoter, and that the ratio of the levels of expression in repressing and non-repressing conditions is larger. This might reflect differences in translation or stability of the hybrid proteins from the fusions, or it might reflect a requirement for a precise interaction between the upstream regulator and the initiation site-proximal sequences, which is altered in the hybrid promoter.

In the DNA sequence[12] between the Δ8 and the Δ2 end points, we noted the presence of a short palindromic sequence

* Yeast strain M12B (*α,trp*1-289, *ura*3-52, obtained from K. Struhl and R. Davis) cells were transformed[19] with the indicated plasmids. The cells were grown in SD minimal media[26] supplemented with uracyl or tryptophan (40 μg ml^{-1}) and the indicated amino acids (1 mM each).

† The leu2 assays were performed in triplicate on exponentially growing cells at a concentration of 10^7 cells per ml as described previously[15]. Units of activity are nmoles *o*-nitro-phenyl-β-D-galactoside (ONPG) cleaved per min per mg of total protein in the extract. The different levels are not due to changes in the segregation properties of the plasmids (data not shown). ND, not determined.

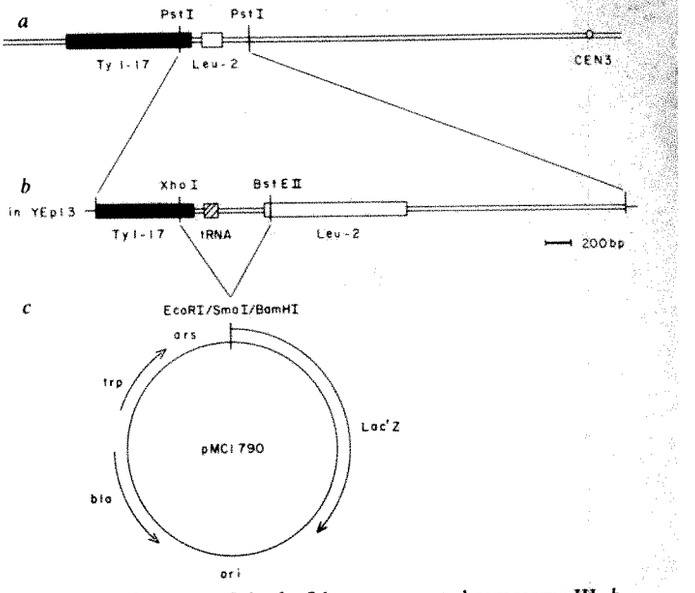

Fig. 1 *a*, Location of the *leu2* locus on yeast chromosome III. *b*, The *Pst*I fragment of the original *leu2* gene cloned in YEp13[27]. The *leu2* gene is transcribed from left to right[15]. There is a Ty*1* element, a $tRNA_3^{Leu}$ gene and an open reading frame (ORF) upstream from the *leu2* coding region[12]. *c*, The fusion plasmid pMC1876 was formed by inserting a blunt-ended *Xho*I–*Bst*EII fragment from YEp13 into the *Sma*I site of vector pMC1790[13], as described previously[14]. This construction has the first 13 *leu2* codons fused in phase to the eighth codon of *lacZ*, so that a hybrid protein with β-galactosidase activity is encoded. *E. coli* strain MC1066[14] carrying plasmid pMC1876 is ampicillin resistant, Trp^+ and expresses β-galactosidase activity detectable on M63 Xgal medium[28]. Note that inserts into the *Sma*I site of pMC1790 are flanked on the left by an *Eco*RI site and on the right by a *Bam*HI site.

(5′ TGAGAGGCCGGAACCGGCTTTTCA 3′) containing two *Hpa*II sites (CCGG) and centred 192 bp from the *leu2* translation initiation codon. Short repeats similar to this have been implicated in the transcriptional regulation of several eukaryotic loci[3,7,22]. To test the involvement of this sequence in the regulation of *leu2* expression, the 6 bp of DNA between the two *Hpa*II sites were deleted (Δ26, Fig. 2) from the fusion (Δ8) lacking the $tRNA_3^{Leu}$ gene. When placed into yeast, this deletion–fusion displayed a very low constitutive β-galactosidase activity and indicates that this G+C-rich palindrome lies within a region important for regulation as well as expression. This small deletion (Δ26) lowers dramatically the basal levels of β-galactosidase expression (Table 1); this might be due to the loss of the functional entry site of RNA polymerase to the *leu2* locus or to the appearance of abnormally initiated transcripts. The assay used in these experiments cannot distinguish between these possibilities. In a second experiment the DNA region between the *Hpa*I and *Hin*cII sites was inverted (InΔ1, Fig. 2). This inversion moves the palindromic sequence 150 bp further upstream of the transcription site. In yeast, this fusion yielded levels of β-galactosidase comparable to the wild-type fusion, but with only a twofold repression by leucine plus threonine (Table 1). These results are consistent with a possible role of this symmetric structure in the regulation of expression at the *leu2* gene.

In an additional experiment aimed at identifying sequences capable of substituting for the *leu2* upstream modulator element by restoring leucine regulated β-galactosidase expression to plasmid Δ2, various DNA sequences were inserted into the *Eco*RI site at the left end of Δ2 *leu2* DNA. One fragment, derived from Tn*9*[23], restored expression comparable to Δ1 with a twofold leucine plus threonine regulation (data not shown). Examination of the sequence of this fragment[24] revealed a 5′ GGTGCGTACCGGGTT 3′ sequence related to the *leu2* repeat region located 170 bp from the *leu2* translation initiation site. Although this region does not contain a perfect palindrome, it embraces a core sequence quite homologous to the one present in *leu2* (see above). This control sequence also appears in a similar position in the promoter of *leu1* (Yun-Pung Hsu and P. Schimmel, personal communication), another leucine biosynthetic pathway gene which is coordinately regulated with *leu2*[25]. Further mutational analysis of the *leu2* control region will be necessary to determine precisely which bases are essential for leucine regulation.

The results presented here exclude any major *cis*-acting regulatory role for the open reading frame upstream of the *leu2* gene. Plasmid HYΔ1 lacks the 3′ end of the open reading frame and still shows *leu2* regulation; on plasmid InΔ1 the open reading frame is disrupted by inversion; and the Tn*9* substitution lacks the 5′ end of the open reading frame. Furthermore, small insertions and deletions around the *Hin*cII site within the open reading frame do not eliminate regulation even in the absence

Table 2 Repression of hybrid promoter *leu2–cyc1*

Plasmid	leu2 activity					
	No amino acids	Leu+Thr	His	Raffinose	No amino acids Leu+Thr	Raffinose: glucose
pMC1876Δ1	940	320	1,000	1,100	2.9	1.2
pLG669Δ292	4,000	5,200	ND	10,400	0.8	2.6
pMC1876HYΔ1	210	30	260	340	7.0	1.6

The *cyc1–lacZ* fusion plasmid[21] pLG669Δ292 contains a 300 bp fragment of the *cyc1* gene from *S. cerevisiae*, a 2μ replicon, and a *ura3* gene as a selectable marker. Amino acids were added at 1 mM each. 2% raffinose was substituted for 2% glucose as the carbon source to determine the response of the fusions to catabolite repression.

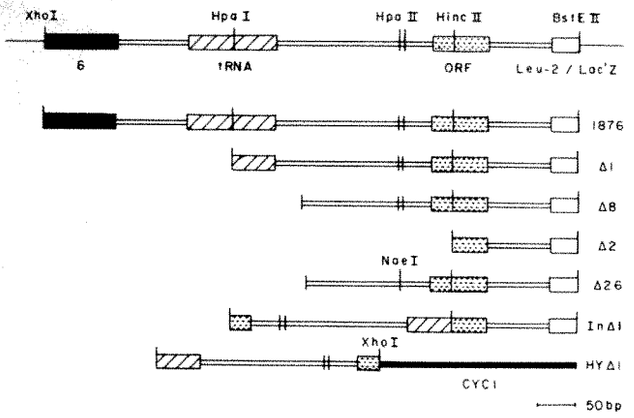

Fig. 2 Derivatives of pMC1876. The Δ1 and Δ8 fragments were obtained by cleaving pMC1876 on the left (*Xho*I side) with *Eco*RI, digestion with the exonuclease *Bal*31 followed by cleavage on the right (*Bst*EII side) with *Bam*HI and isolation in 4.5% polyacrylamide gels. Δ2 is a *Hin*cII–*Bam*HI fragment of pMC1876. The Δ1, Δ8 and Δ2 fragments were inserted into pMC1790 cleaved with *Sma*I and *Bam*HI. Δ26 is a 6 bp *Hpa*II deletion obtained by isolating the *Eco*RI–*Bam*HI fragment of Δ8, cleaving with *Hpa*II, and ligating the two large fragments from this reaction (eluted from a polyacrylamide gel) back into pMC1790 cleaved with *Eco*RI and *Bam*HI. This construction was verified by the observation that the deletion of the 6 bp between the *Hpa*II sites (5′ GCCGGAACCGGC 3′) creates a *Nae*I site (5′ GCCGGC 3′). The hybrid *leu2–cyc1* promoter was formed by cleaving the derivative of Δ1, containing an *Eco*RI–*Sma*I–*Bam*HI linker at the *Hin*cII site, with *Sma*I and *Sac*I (a unique restriction site in the middle of *lacZ*) and ligating the purified vector fragment to a fragment containing the *cyc1* transcription and translation initiation sites from pLG669Δ292[21] cleaved with *Xho*I, rendered blunt, and cleaved with *Sac*I. All clones were selected in *E. coli* strain MC1066 as ampicillin resistant, Trp^+ colonies displaying β-galactosidase activity on M63 Xgal medium. Note that the fusion points in *lazZ* of the *cyc1* and the *leu2* are different. DNA manipulations[29], strains and methods of selection used[14] have been described previously. The end points of Δ1, Δ8 and Δ2, and the centre of the palindromic repeat are located 400 ± 10, 310 ± 10, 125 and 192 bp respectively before the *leu2* initiation codon.

of the chromosomal copy of the open reading frame at the *leu2* locus (unpublished results).

Mutations at upstream modulator elements, similar to our Δ26, affect both gene regulation and expression systems that have been investigated[4,7,17]. This phenomenon has been interpreted as evidence that these sequences mediate positive regulatory mechanisms at these loci and thus may represent binding sites for specific proteins whose function is to open the chromatin structure locally, allowing RNA polymerase positioning. Alternatively these elements may be entry sites for the RNA polymerase destined to initiate transcription at the downstream TATA box.

We thank A. Andreadis and P. Schimmel for communicating unpublished results, L. Guarante for sending pLG669Δ292, and L. Rothman-Denes and C. Giroux for constructive criticism of the manuscript. Expression and regulation of human low-density lipoprotein receptors in Chinese hamster ovary cells

Robert D. Sege, Karen Kozarsky, David L. Nelson & Monty Krieger*

Department of Biology, Whitaker College of Health Sciences, Technology and Management, and the Center for Cancer Research, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

Low-density lipoprotein (LDL), the major cholesterol transport component of human plasma, delivers cholesterol to mammalian cells via the LDL pathway of receptor-mediated endocytosis[1]. LDL receptor activity and cholesterol biosynthesis are coordinately regulated by cholesterol-mediated feedback suppression[2–4]. We have developed methods for the isolation of mutant[5,6] and revertant (M.K., unpublished data) Chinese hamster ovary (CHO) cells having alterations in cholesterol biosynthesis and in the receptor-mediated endocytosis of LDL. The defective locus of one LDL receptor-negative CHO mutant (clone 7a-1)[6] is apparently the structural gene for the LDL receptor (D. Kingsley, M. Segal and M.K., unpublished data). Here we have transfected 7a-1 cells with human DNA and selected colonies which synthesize functional human LDL receptors whose expression is regulated normally. This selection may prove useful for cloning genes required for the receptor-mediated endocytosis of LDL and other ligands and thus for elucidating the molecular defects responsible for familial hypercholesterolaemia, one of the most common genetic diseases in humans[7].

Human DNA was introduced into the LDL receptor-negative clone 7a-1 by the $CaPO_4$ method[8,9] and cells were selected in MeLoCo medium as described in Fig. 1 legend. In this selective medium the cells die from cholesterol deprivation unless they can obtain cholesterol by the endocytosis of LDL[5,6,10,11]. Colonies survived continuous selection in MeLoCo medium at a frequency of 2×10^{-7} (6 colonies per 3×10^7 cells). This frequency of survival was ~1,000-fold lower than that obtained when the neomycin analogue G418 was used to select pSV2-neo transfected cells[12] (data not shown). Two of the colonies which survived MeLoCo selection, designated LET-1 and LET-2 (LDL endocytosis transfectants), were selected for further study. These colonies contained discrete DNA sequences homologous to human repetitive DNA (*Alu* family), whereas untreated 7a-1 cells did not (Fig. 1).

The expression of the LDL receptor pathway in LET-1 and LET-2 was compared with that in parental CHO and receptor-negative 7a-1 cells by measuring the specific cellular binding,

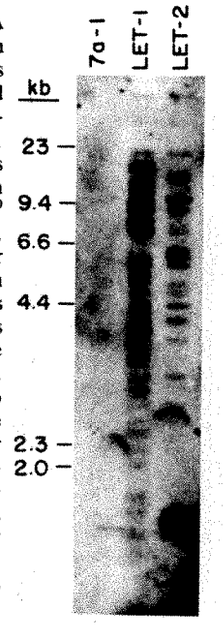

Fig. 1 Detection of human repetitive DNA sequences in CHO cells following transfection and selection. All cells were cultured in Ham's F-12 media supplemented with the indicated sera as described previously[5,6,13]. DNA, isolated from LDL receptor-negative clone 7a-1 and transfected LET-1 and LET-2 cells, was digested with *Eco*RI and analysed by Southern blot[28,29] hybridization with ^{32}P-labelled[30] cloned human *Alu* family (BLUR11)[31] DNA. Kodak XAR-5 film was exposed at −70 °C for 20 h with a Cronex Lightning Plus screen (Dupont). LDL endocytosis transfectants (LETs) were obtained as follows: 7a-1 cells were transfected with human DNA using the $CaPO_4$ technique[9] with minor modifications. DNA was extracted[32] from portions of two human fetal livers which were pulverized in the presence of liquid nitrogen[33] and further purified by sequential digestion with ribonuclease A (Sigma) and proteinase K (Boehringer-Mannheim). 24 h before transfection, the cells were plated (7.5×10^5 cells per 100 mm plate) in 10% newborn calf serum (NCS) and the DNA was sheared three times through a 21-gauge needle (final length >45 kilobases (kb) by agarose electrophoresis) and precipitated by overnight incubation with ethanol at −20 °C. The precipitate was dissolved (30 μg ml^{-1}) in HEPES-buffered saline (HBS), *p*H 7.1. The $CaPO_4$/DNA coprecipitate was allowed to form for 45 min at room temperature, and added (1.0 ml per dish) to cell monolayers from which medium had been removed. After incubation for 20 min at room temperature, fresh 10% NCS was added and the plates were incubated at 37 °C for 4.5 h. Cells were then treated with 15% glycerol in HBS; 2 days later, cells were replated (7.5×10^5 cells per 100 mm dish) in selective medium (3% newborn calf lipaprotein deficient serum (NC-LPDS) containing a mixture of mevalonate (238 μM), LDL (2.8 μg protein ml^{-1}) and compactin (38 μM), called MeLoCo)[5,6,10,11]. The compactin inhibits synthesis of mevalonate and thus inhibits synthesis of steroidal and non-steroidal isoprenoids; the trace levels of mevalonate permit the synthesis of non-steroidal but not steroidal isoprenoids; and the LDL serves as a source of sterol for cells which express the LDL pathway. Most of the cells began to die within 3 days and macroscopic colonies of survivors were visible by eye after 13–17 days of selection. These colonies (LETs) were picked[34] and subsequently maintained in selective medium. An analogous selection relying on the reversal of nutritional deficiencies by receptor-mediated delivery of inorganic ions has been suggested[35].

uptake and degradation of ^{125}I-LDL (10 μg protein ml^{-1})[13]. Relative degradation activities were: parental CHO, 100%; LET-1, 184%; LET-2, 93%; and 7a-1, 2%. The saturation kinetics of ^{125}I-LDL degradation by LET-1 (Fig. 2) and LET-2 (data not shown) cells exhibited high affinity and saturability, hallmarks of the classic LDL pathway[14]. The affinity of LET-1 cells for LDL at 37 °C (K_m 16 μg protein ml^{-1}) was twice as strong as that of parental CHO cells (K_m 35 μg protein ml^{-1}) and was essentially equal to that of human LDL receptors (K_m 17 μg protein ml^{-1})[15]. LET-1 bound twofold more LDL than CHO cells at 4 °C (data not shown), and the ratio of ^{125}I-LDL internalization and degradation to surface binding, that is, the efficiency of the LDL pathway[16], in LET-1 cells (ratio 23) was essentially identical to that in CHO cells (ratio 24, data not shown).

These results suggested that LET cells survived selection because transfection and expression of the human LDL receptor gene complemented the mutation in clone 7a-1. Therefore, synthesis of the human LDL receptor (an ~160,000-molecular weight (MW) monomeric glycoprotein)[17] was examined by immunoprecipitation and electrophoresis[18]. A previously described[19] monoclonal antibody against bovine LDL receptor (IgG C7) cross-reacted with and inhibited LDL binding to human LDL receptors (Fig. 3*a* and ref. 19) but not to LDL receptors from CHO cells (Fig. 3*b* and ref. 19). No specific immunoprecipitable protein was detected in 7a-1 cells

Table 1 Degradation of ^{125}I-LDL by LET-1 cells: inhibition by anti-human receptor antibody and regulation by LDL and sterols

	^{125}I-LDL degradation (% of control)	
	Parental CHO cells	LET-1 cells
Expt *a*		
Additions to assay medium		
None	100	100
IgG C7 (190 nM)	104	49
IgG 2001 (190 nM)	121	117
Expt *b*		
Additions to growth medium		
None	100	100
LDL (300 μg protein ml^{-1})	25	35
Cholesterol (12.5 μg ml^{-1})	72	77
Cholesterol + 25-hydroxy-cholesterol (0.5 μg ml^{-1})	24	39

Expt *a*: On day 0, parental CHO and LET-1 cells were plated in 1.5 ml of 3% NC-LPDS in 24-well plates (60,000 cells per well). On day 2, each monolayer was preincubated for 1 h with 0.5 ml of 3% NC-LPDS containing either no additions or 190 nM of anti-bovine (human) LDL receptor monoclonal antibody (IgG C7) or control antibody (IgG 2001). Each monolayer was re-fed with 5% H-LPDS containing the same additions plus 10 μg protein ml^{-1} of ^{125}I-LDL (247 c.p.m. ng^{-1}). After incubation at 37 °C for 5 h, the amount of ^{125}I-LDL degradation products released into the medium was determined. The values are expressed as a percentage of the high affinity values for the cells incubated in the absence of antibody. The 100% control values were: CHO, 1,795 ng per 5 h per mg; LET-1, 4,034 ng per 5 h per mg. Expt *b*: In a separate experiment, cells were plated on day 0 as described above. On day 1, the medium was replaced with 1 ml of 3% NC-LPDS containing the indicated additions of LDL, cholesterol in ethanol or cholesterol plus 25-hydroxycholesterol. On day 2 (23 h later), each monolayer was washed once with phosphate-buffered saline, then 0.5 ml of 5% H-LPDS containing 10 μg protein ml^{-1} of ^{125}I-LDL (446 c.p.m. per ng protein) was added and high affinity degradation was determined. The high affinity values are expressed as the percentage of the values for the same cells incubated with no additions. The 100% control values were: CHO, 1,293 ng per 5 h per mg; LET-1, 2,698 ng per 5 h per mg. The thrombin used to isolate H-LPDS was given by the Parke-Davis Division of Warner Lambert.

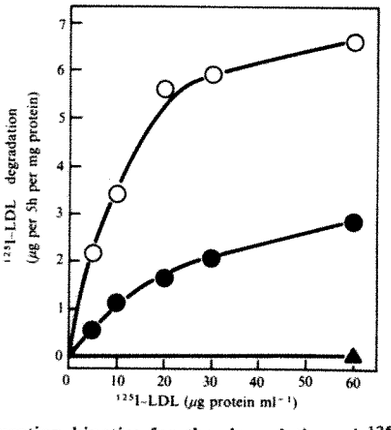

Fig. 2 Saturation kinetics for the degradation of ^{125}I-LDL at 37 °C by monolayers of parental CHO, LDL receptor-negative clone 7a-1 and LET-1 cells. On day 0, parental CHO (●), clone 7a-1 (▲) and LET-1 (○) cells were seeded in 1.5 ml of 3% NC-LPDS into 24-well plates (60,000 cells per well). On day 2, each monolayer received 0.5 ml of 5% human lipaprotein deficient serum (H-LPDS) containing the indicated amounts of ^{125}I-LDL (442 c.p.m. per ng of protein). After incubation at 37 °C for 5 h, the amounts of ^{125}I-LDL degradation products released into the media were determined as described previously[13]. Data are expressed as high affinity values for degradation.

(Fig. 3*a*, *b*). IgG C7 specifically precipitated one protein of MW ~ 160,000 from both LET-1 (Fig. 3*a*, *b*) and LET-2 (Fig. 3*b*). IgG C7 also specifically inhibited degradation of ^{125}I-LDL by LET-1 but not by parental CHO cells (Table 1, expt *a*). Thus, human LDL receptors in these hamster cells are respon-

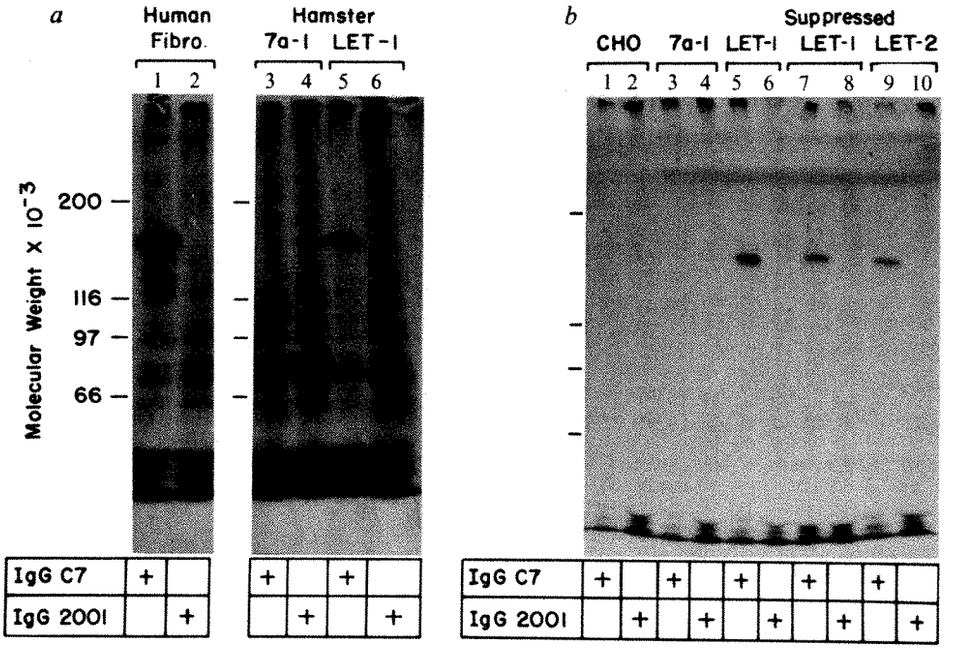

Fig. 3 Immunochemical detection of human LDL receptors in transfected hamster (LET) cells: regulation of expression by LDL. *a*, On day 0, normal human diploid fibroblasts (GM3349)[13] were plated in 3 ml of 10% fetal bovine serum in 60 mm dishes (50,000 cells per dish). On day 2, the monolayers were re-fed, then on day 5 they were washed and re-fed with 3 ml of 10% H-LPDS. In addition, LDL receptor-negative clone 7a-1 cells and human DNA transfectants of clone 7a-1 (LET-1) were plated on day 5 in 3 ml of 3% NC-LPDS (300,000 cells per 60 mm dish). On day 6, all monolayers were re-fed with either 10% H-LPDS (fibroblasts) or 3% NC-LPDS (7a-1 and LET-1 cells) prepared using methionine-free Ham's F-12 medium (K-C Biologicals) supplemented with 50 μCi ml^{-1} of ^{35}S-methionine (NEN) and 5 μM unlabelled methionine (Sigma). After 16 h, the monolayers were washed, lysed, and immunoprecipitated with either anti-bovine (and human) LDL receptor antibody (IgG C7: lanes 1, 3 and 5) or control antibody (IgG 2001: lanes 2, 4 and 6) as described[18]. Each lane represents immunoprecipitates derived from 6.4×10^7 (A) or 10^8 (B) c.p.m. of labelled cell extract. The immunoprecipitates were subjected to SDS-6% polyacrylamide gel electrophoresis[36] (7 mA per gel) for 18 h, impregnated with Autofluor (National Diagnostics), dried and subjected to autoradiography (Kodak XAR-5 film at −70 °C for 7 days with a Cronex Lightning Plus screen). *b*, Parental CHO, 7a-1, LET-1 and LET-2 cells were plated on day 5 as described above except that the LET-1 monolayers were divided into two groups. The first group (lanes 5 and 6) was plated in 3% NC-LPDS as were the other cell strains (see above). The second group, 'suppressed LET-1' (lanes 7 and 8), was plated and labelled in 3% NC-LPDS containing LDL (300 μg protein ml^{-1}). The cells were processed for immunoprecipitation with IgG C7 or IgG 2001 as indicated, and for electrophoresis and fluorography (24 h exposure) as described above.

sible for the receptor-mediated endocytosis of LDL.

A distinctive feature of the LDL pathway is the feedback suppression of receptor activity by sterols[2]. When parental CHO and LET-1 cells were incubated with regulatory sterols (cholesterol, the potent analogue 25-hydroxycholesterol[20], or esterified cholesterol delivered by LDL[2,21]), receptor activity was suppressed to essentially the same extent (Table 1, expt *b*). Receptor activity in LET-2 cells was similarly suppressed by LDL (data not shown). The sterol-mediated suppression of LDL receptor activity in human fibroblasts is due to a decrease in the number of LDL receptors[19]. Similarly, the suppression of LDL receptor activity in LET-1 cells was associated with a reduction in the amount of immunoprecipitable LDL receptor protein (Fig. 3*b*, compare lane 7 with lane 5). Thus, the expression of the human LDL receptor gene in transfected hamster cells was subject to the same sterol-mediated regulatory control as that observed in normal human[2] and hamster[13] cells.

The present studies show that selection in MeLoCo medium can be used to isolate receptor-positive transfectants from a population of receptor-negative (mutant) cells. Using the method of Shih and Weinberg[22], it should be possible to clone the LDL receptor gene and combine the techniques of *in vitro* gene manipulation (for example, see ref. 23) and MeLoCo selection to explore the mechanism by which the expression of LDL receptors is regulated. Also, it may be possible to exploit previously described selection methods[5,6] to isolate mutant LET cells having defects in human LDL receptors and compare these mutant LDL receptors with the naturally occurring mutant LDL receptors from familial hypercholesterolaemia patients[18].

Chemical modification of LDL can be used to re-target the delivery of cholesterol through other surface receptors[24,25,37]; therefore, it may be possible to use MeLoCo selection to express a wide variety of exogenous receptors (including tissue-specific receptors) in CHO cells and eventually to clone the genes for these receptors. This approach complements a previously described two-step procedure in which cells co-transfected with genomic DNA and a selectable gene were isolated and screened by flow cytometry for the expression of surface antigens (for example, the transferrin receptor[26] and histocompatibility antigens[27]). In contrast, MeLoCo medium directly selects for receptor function without immunochemical reagents. MeLoCo selection may prove useful for cloning the genes, other than those of receptors, which have been defined by somatic cell mutations to be required for the expression of LDL receptors (ref. 13 and D. Kingsley, M. Segal and M.K., in preparation).

We thank Julianna Martin and Marsha Penman for technical assistance; Kathy Thurmond for preparation of the manuscript; Drs J. Goldstein, M. Brown, W. Schneider and Y.-K. Ho for providing the monoclonal antibodies and for advice about immunoprecipitations; Dr R. Rosenberg for permitting access to his γ-spectrophotometer; Dr A. Schwartz for providing the liver specimens; Dr A. Endo for supplying compactin; S. Lewis for the gift of psv2-neo DNA; Dr D. Housman, Dr J. Cunningham and R. Cone for advice regarding transfection methodology; and D. Kingsley for a critical review of the manuscript. This research was supported by a March of Dimes Basil O'Connor Research Grant and a NIH research grant. M.K. was the recipient of a NIH Research Career Development Award and R.D.S. was supported by a NIH Medical Scientist Training Program grant (GM07753) through Harvard Medical School.

Monoclonal antibodies localize oestrogen receptor in the nuclei of target cells

W. J. King & G. L. Greene*

Ben May Laboratory for Cancer Research, University of Chicago, 5841 South Maryland, Chicago, Illinois 60637, USA

Although it is widely accepted that specific intracellular receptor proteins are involved in the oestrogenic regulation of gene expression and growth in reproductive tissues, the precise nature of the regulation is poorly understood. Among the unresolved issues are the distribution and dynamics of the oestrogen receptor protein (oestrophilin) in target tissues in the presence and absence of oestrogens and antioestrogens. The use of radiolabelled and unlabelled receptor ligands to detect and measure oestrogen receptors in tissues has been complicated by the presence of other intracellular steroid-binding proteins[1] and by the low concentration of receptors in responsive tissues. We report here the development of an immunocytochemical procedure that is suitable for localizing oestrophilin directly in frozen tissue sections or cells from human and several non-human sources. When monoclonal antibodies to oestrophilin were used to detect receptor in various oestrogen-sensitive tissues, specific staining was confined to the nucleus of all stained cells, suggesting that both cytosol and nuclear forms of the receptor protein may reside in the nuclear compartment.

Five monoclonal rat antibodies (D547Spγ, D58P3μ, D75P3γ, H222Spγ, and H226Spγ)[2–5], which have been shown to be oestrogen receptor-specific by several criteria, were used individually to localize oestrophilin by an indirect immunoperoxidase technique[6] in frozen, fixed sections of human breast tumours (Fig. 1), human uterus, rabbit uterus (Fig. 2), and in other mammalian reproductive tissues, as well as in fixed MCF-7 cell cultures (Fig. 3). The nuclear staining observed in each case fulfilled all of the accepted criteria for specificity[7,8], including its dependence on the presence (compare Figs 1*b*, 2*b* and 3*b* with 1*a*, 2*a* and 3*a*) and concentration of monoclonal antioestrophilin and the susceptibility of such staining to competitive inhibition by highly purified oestrophilin (Figs 1*e*, 2*e*). Specific nuclear staining was either absent or limited to a few cells in receptor-poor breast cancers (Fig. 4); nontarget tissues such as colon epithelium were always negative. Specific staining for oestrophilin in MCF-7 cells, like that in many human breast tumours, was heterogeneous and also confined to the nucleus (Fig. 3). Staining heterogeneity may reflect the polyclonal origins of these specimens[9], or it may be related to the physiological status (for example, cell cycle) of the cell populations. Little or no specific cytoplasmic staining for oestrophilin has been observed in any of the tissues or tumour cells examined thus far, including those which have been deprived of exogeneous oestrogens for extended times due to postmenopausal amenorrhea or experimental intervention.

For basic studies of receptor dynamics in oestrogen-responsive tissues and cells, the immunoperoxidase technique must be applicable to animal models and cultured tumour cells. Two monoclonal rat antibodies, H222Spγ and H226pγ, which cross-react with all tested mammalian and avian oestrophilins[10], were used to test the method on oestrogen target tissues from the rabbit. A pattern of predominantly nuclear localization identical to that found in human tissues was observed in sections of rabit uterus (Figs 2*a*, 2*d*), oviduct, corpus luteum, mammary gland, pituitary and liver, but not in colon epithelium. The specificity of the staining patterns in rabbit tissues was confirmed by application of the same controls used for human breast tumours, as shown for rabbit uterus in Figs 2*b*, 2*c* and 2*e*. Animals used in this study were either sexually immature or experimentally deprived of endogenous oestrogens by ovariectomy or induction of pseudopregnancy[11]. In each case, 70% to 95% of the unoccupied oestrophilin was found in low-salt cytosols, as determined by steroid-binding assays (see legend to Fig. 2).

The nuclear localization of immunoperoxidase staining for oestrogen receptor is surprising as the generally accepted hypothesis is that receptor resides primarily in the cytoplasm of target cells in the absence of steroid[12–14]. However, early autoradiographic evidence that radioactive steroid incorporated by rat uteri on exposure to ^{3}H-oestradiol at 2 °C *in vitro* is mostly extranuclear[15] has recently been challenged on the basis of similar autoradiographic studies in which binding in the cold appeared to be predominantly nuclear[16]. Similar histochemical[17–19] and immunohistochemical[20,21] evidence for cytoplasmic receptor sites has been challenged on the basis that the oestrogen derivatives used are bound to lower-affinity intracellular binding sites other than oestrogen receptor[1] or that receptor diffuses out of unfixed frozen sections during localization[22]. A recent report[23] of cytoplasmic localization of oestrogen receptor with polyclonal antioestrophilin antibodies raised against an impure preparation of human breast tumour oestrophilin lacks supporting evidence of complete antibody specificity for oestrophilin.

It is unlikely that the absence of cytoplasmic staining in the current study is due to the duration of fixation, solubilization of the receptor protein, or to artifactual translocation of receptor during fixation or processing of tissues or cells. The uniformity of our results under a variety of conditions, including treatment of tissues and intact cells with both precipitating and crosslinking fixatives before and after sectioning or freezing, and at temperatures ranging from 4 to 37 °C, suggests that receptor is being permanently immobilized without redistribution. Extending fixation times beyond 1–2 h results only in a progressive loss of nuclear staining without any increase in cytoplasmic staining above background levels. In addition, cytosolic oestrophilin covalently labelled with ^{3}H-tamoxifen aziridine, an antioestrogen derivative[24], precipitates quantitatively in 35% aqueous ethanol and remains insoluble when exposed to PBS (unpublished observation). Receptor-containing tissue sections treated with the same fixative show only nuclear staining.

These immunocytochemical results indicate that oestrogen receptor may reside primarily in target cell nuclei of oestrogen-sensitive tissues and tumours both in the presence and absence of steroid, analogous to what has been reported for the vitamin D and thyroid hormone receptors[25–29]. The oestrophilin recovered in the cytosol fraction of a homogenate would then represent receptor that is loosely associated with the nucleus and it would follow that the binding of oestradiol to its receptor leads to a tighter association, a phenomenon previously interpreted as indicating translocation of the receptor from the

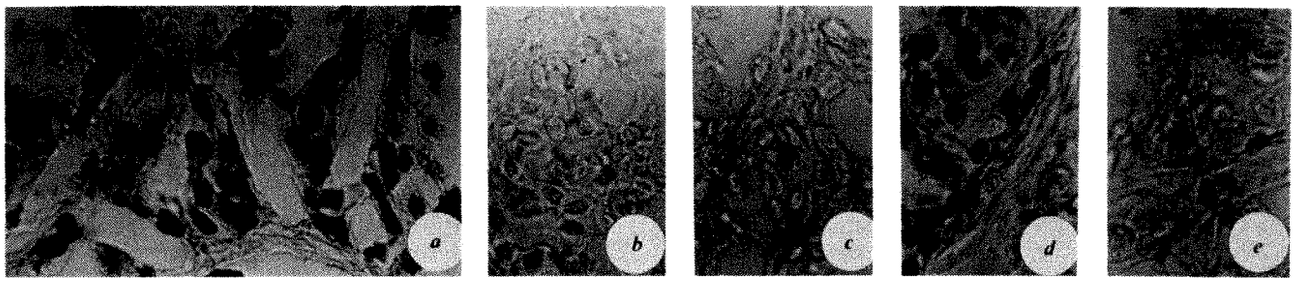

Fig. 1 Immunocytochemical localization of oestrogen receptor in a breast tumour taken from a 67-year-old postmenopausal woman, and which contained 1,546 fmol of cytosolic oestrogen receptor per gram wet weight, as measured by sucrose density gradient analysis[3]. Frozen sections (8 μm) were thaw-mounted on uncoated glass slides and fixed with picric acid-paraformaldehyde[30] for 10 min at 23 °C. After fixation, sections were rinsed with phosphate-buffered saline (PBS) and treated with a 10% (w/v) solution of ovalbumin in PBS to minimize the nonspecific binding of reagents in subsequent steps. Tissue sections were then incubated successively with one or more monoclonal antibodies, goat antibody to rat IgG, and rat peroxidase-antiperoxidase complex (PAP) for 30 min each at ambient temperature in a humidified chamber. Each incubation was followed by a 5-min wash with PBS. Specifically bound antibodies were visualized by immersing the sections for 10–30 min in a solution of diaminobenzidine (1.7 mM) and hydrogen peroxide (0.06%) in PBS. *a–e*, sections were treated identically, except for the first incubation which consisted of either (*a*) 2 μg ml^{-1} (13.4 pmol ml^{-1}) of H226Spγ antibody in PBS; (*b*) 2 μg ml^{-1} of purified normal rat IgG in PBS; (*c*) 2 μg ml^{-1} of H226Spγ in MCF-cytosol (20 pmol receptor per ml); (*d*) 2 μg ml^{-1} of H226Spγ in receptor-depleted (by selective adsorption to estradiol-Sepharose[4]) MCF-7 cytosol (2 pmol receptor per ml); or (*e*) 2 μg ml^{-1} of H226Spγ in receptor-depleted MCF-7 cytosol supplemented with 20 pmol ml^{-1} of highly purified (~90% pure) oestrophilin[10,31]. Original magnification, ×400. The specificities of the antibodies used in this study were tested extensively by Western blot, sucrose gradient[2–4], double antibody precipitation[2] and indirect enzyme immunoassay (EIA) techniques. Regardless of the technique employed, each of the antibodies appears to be completely specific for oestrogen receptor. When ^{35}S-labelled H222Spγ and H226Spγ IgGs were used to detect immunoreactive proteins on nitrocellulose blots of SDS gels after electrophoresis of low and high salt extract of MCF-7 cells, both antibodies recognized a single protein band (molecular weight, 65,000), which corresponded to highly purified receptor. The same band was obtained when crude oestrophilin was isolated by immunoadsorption to a column of D547Spγ-Sepharose and eluted with SDS.

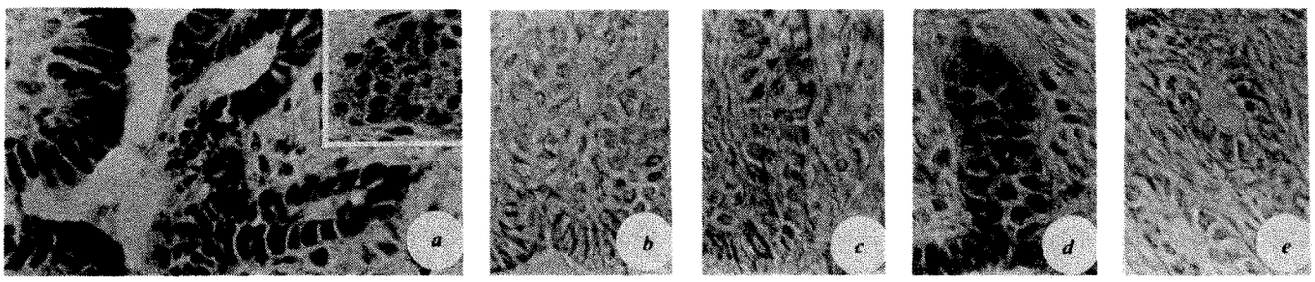

Fig. 2 All procedures were the same as Fig. 1, except that sections were prepared from a uterus taken from a rabbit ovariectomized 8 days prior to killing. Uteri from similarly treated rabbits were found to contain 3.15 ± 0.85 pmol cytosolic receptor per mg of DNA ($n = 3$) and 0.16 ± 0.01 pmol of high-salt (0.4 M KCl) extractable receptor per mg of DNA, as measured by exchange assay with ^{3}H-oestradiol[32]. The insert in the upper right corner of Fig. 2*a* represents rabbit myometrium.

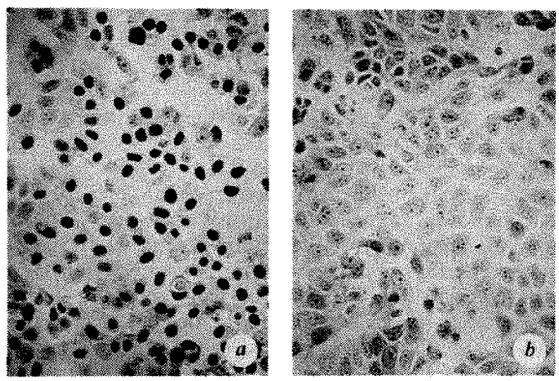

Fig. 3 Localization of oestrogen receptor in MCF-7 human breast cancer cells. Cells were grown on chambered glass slides, fixed for 10 min with picric acid-paraformaldehyde[30] and oestrogen receptor was localized as described in Fig. 1 using 10 μg ml^{-1} of H226Spγ antibody in PBS (*a*). Cells shown in (*b*) were treated identically except that 10 μg ml^{-1} of normal rat IgG was substituted for the monoclonal antibody.

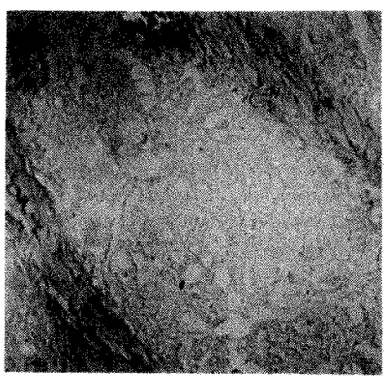

Fig. 4 Absence of nuclear staining in a human receptor negative (0 fmol g^{-1} tissue) breast tumour from a postmenopausal patient. Staining conditions were as described in Fig. 1, using 10 μg ml^{-1} of H226Spγ antibody in PBS. Original magnification, ×400.

cytoplasm to the nucleus[12]. In support of our hypothesis, we have seen little or no increase in nuclear staining intensity in MCF-7 cells and immature or ovariectomized rabbit uteri following short-term treatment of cells or animals with oestradiol. Our observations are clearly inconsistent with the concept of steroid-induced receptor translocation, suggesting that the classical 'two-step' model[12] for oestrogen action requires reinterpretation.

We acknowledge Dr Larry Miller of Abbott Laboratories, North Chicago, who developed the H226 and H222 antibodies used in this study. We were supported by research grants from the ACS (BC-86), Abbott Laboratories, NCI (CA-02897), and by the Women's Board of the University of Chicago Cancer Research Foundation. W.J.K. was supported by a postdoctoral training grant (NIH/NCI 09183) and by the NCI (CA 14599).

Nuclear localization of unoccupied oestrogen receptors

Wade V. Welshons, Mara E. Lieberman & Jack Gorski

Departments of Biochemistry, Human Oncology and Animal Science, University of Wisconsin-Madison, Madison, Wisconsin 53706, USA

According to the current model of steroid hormone action oestrogen is thought to bind to its receptor in the cytoplasm of target cells[1,2] and the oestrogen–receptor complex is then translocated into the nucleus[2–4]. This model is based on evidence obtained in homogenized cell preparations in which free receptor is associated with the cytosol, whereas steroid-bound receptor is associated with the nuclear fraction. Some data suggest, however, that the unfilled receptor may reside in the nucleus, and that cytosolic localization represents an extraction artefact. We have now reinvestigated the subcellular distribution of unfilled oestrogen receptor using cytochalasin B-induced enucleation to obtain cytoplast and nucleoplast fractions from receptor-containing GH_3 cells derived from rat pituitary tumours. We found that cytoplasts prepared from GH_3 cells contain little oestrogen-binding activity and that most of the unfilled oestrogen receptors are associated with the nuclear fraction. We therefore suggest that the standard model is in error and that the unoccupied receptor is nuclear in the intact cell.

If unfilled oestrogen receptor is cytoplasmic, the receptor concentration in the cytoplasts should be greater than the concentration in whole cells. In fact, when cells were enucleated (Fig. 1) the concentration of receptor relative to protein was greatly reduced in cytoplasts and increased in the fraction containing cells and nucleoplasts compared with intact cells (Fig. 2). In contrast, receptor relative to DNA was similar in all cell preparations (Fig. 2), indicating that the receptor is associated with nuclear rather than cytoplasmic elements. In an experiment using cytoplasts that contained particularly few contaminating whole cells (0.25%), the concentration of receptor relative to protein was less than 10% of that found in intact cells (Table 1). In four enucleation experiments the recovery of protein, DNA or oestrogen receptor was 93, 97 or 104%, respectively. The essentially complete recovery indicates that receptor was not selectively lost from cytoplasts.

The cell + nucleoplast fraction was further fractionated by centrifugation to obtain cells from which a larger proportion of the cytoplasm had been removed. Receptor more than doubled relative protein (Fig. 3, fraction C), whereas the receptor: DNA ratio was constant.

The cytoplasts obtained following enucleation are approximately one-fifth the size of whole cells, according to protein content (Table 1) and 75% or more of the cells appear to form cytoplasts (Fig. 1). The cytoplasts exclude trypan blue (98%), incorporate ^{3}H-leucine into protein generally and prolactin specifically (data not shown). Specific oestrogen binding by whole cells (or whole cytoplasts) was saturable with K_d of 3.4×10^{-10} M by Scatchard analysis, and there were usually 20,000–30,000 oestrogen-binding sites per cell.

Incubation of whole cells in enucleation medium (Percoll, cytochalasin B, dimethyl sulphoxide (DMSO)) did not significantly change the number of receptors per cell or the distribution of receptor between the cytosol and the crude nuclear pellet in homogenized cells (data not shown). This confirms earlier studies with intact uteri in which cytochalasin had no effect on the uptake of oestradiol, the binding, or the distribution of filled receptors in homogenized tissue[5].

Our finding that the oestrogen receptor is predominantly nuclear, whether or not it is bound to the steroid, contradicts a large body of evidence which has been interpreted to indicate that the free oestrogen receptor is a cytoplasmic protein. There are, however, several earlier reports in the literature which are compatible with our findings. These include autoradiographic localization of most of hormone binding to the nucleus in 'non-translocation' conditions[6], appearance of 4S 'cytoplasmic' receptor in nuclei of some tissue before 5S 'nuclear' forms which appear after binding of the hormone[7], and evidence that some oestrogens produce full physiological effects even though the receptor appears entirely in cytosol extracts of homogenized cells[8,9]. The unfilled vitamin D receptor and thyroid hormone receptor have been reported to be nuclear in homogenized cells[10,11], and cell lines have been described in which unfilled oestrogen receptor remains nuclear in homogenized cells[12] until nuclei are washed and extracted more rigorously[13].

In contrast to earlier immunohistochemical studies which showed cytoplasmic localization of receptor[14–16], a recent immunocytochemical study indicates that antibodies to the oestrogen receptor interact only with nuclei of human endometrium or human mammary tumour cells, whether or not oestrogen is present[17].

In the present study we used GH_3 cells, a clonal strain derived from a rat pituitary tumour[18,19] that contain oestrogen receptors[20] localized in the cytosol after the usual cell disruption procedures[20,21]. GH_3 cells, including the specific strain used here, respond to oestrogen by increased prolactin synthesis[22,23]. The concentration of oestrogen receptor in cytoplasts was only 5–10% of that observed in intact cells. This was not due to degradation of receptor during enucleation, because all of the binding activity was recovered in the fraction enriched in nuclei. It is unlikely that the cytoplasts were formed from a small, atypical subpopulation of cells that were deficient in receptor,

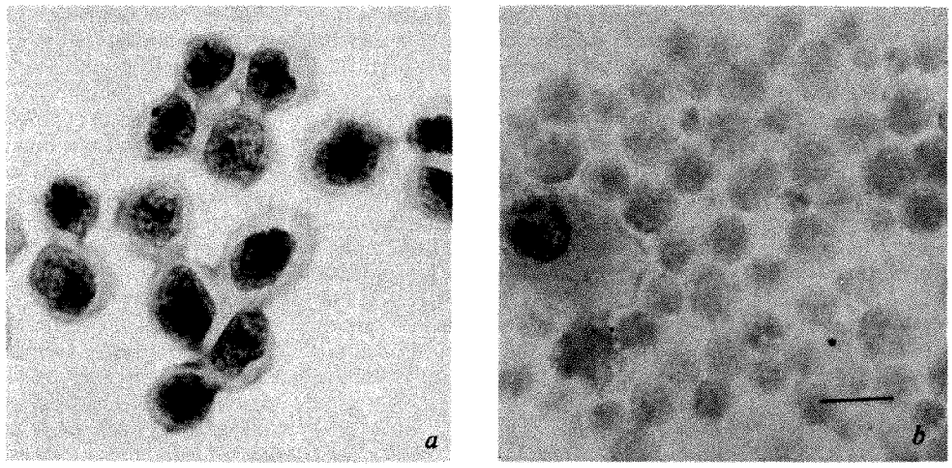

Fig. 1 Feulgen-stained whole cells (*a*) and cytoplasts (*b*) or cells + nucleoplasts (*c*) after enucleation. Enucleation of GH_3 cells yielded cytoplasts with diameters up to approximately 50% that of whole cells, and nucleoplasts plus cells with varying amounts of cytoplasm. Scale bar, 10 μm.

Methods: GH_3 cells were grown in Dulbecco's minimum essential medium (DMEM, Gibco) containing HEPES 25 mM, penicillin (Sigma) 100 U ml^{-1}, Fungizone (Gibco) 0.5 μg ml^{-1} and 17.5% horse-fetal calf serum (Gibco) 6:1. Charcoal-stripped serum was used throughout, or for the last medium change, with similar results. Cells were removed from the tissue culture dish by incubating in 1 mM EDTA in calcium–magnesium-free Hanks' balanced salt solution + 25 mM HEPES (CMFH) for 10 min at 37 °C. Cells were enucleated by the cytochalasin B-equilibrium centrifugation method of Bossart *et al.*[24], with modifications. For preparation of cytoplasts that were contaminated with few nucleated cells, a narrow density range of cells was selected before enucleation. This was accomplished by applying cells ($20–40 \times 10^6$ per 13-ml tube) to a step-gradient of Percoll (Pharmacia) in CMFH, with steps of 1.04, 1.05, 1.058, 1.063 and 1.07 g ml^{-1}. After a 20-min spin at 400*g* in a swinging bucket centrifuge, the predominant band was collected, usually at 1.058–1.063 g ml^{-1}. The cells were diluted 5× in CMFH, pelleted (125*g*, 10 min) and resuspended in Percoll of 1.075 g ml^{-1} (for cells from 1.058–1.063 g ml^{-1}), containing cytochalasin B (Aldrich) at 20 μg ml^{-1} and solvent DMSO 20 μl ml^{-1}, $5–10 \times 10^6$ cells per ml. The cells were incubated at 37 °C for 45 min, then layered onto more of the Percoll plus cytochalasin B (10–20 μg ml^{-1}), 37 °C, in a clear ultracentrifuge tube, and then spun at 64,000*g* for 45 min at 37 °C in a Beckman SW41 swinging bucket rotor. At 1×10^7 cells per gradient (12 ml total), cytoplasts could be recovered with minimal contamination by whole cells (<1%), but for higher yields, up to 40×10^6 cells were applied, which resulted in cytoplast preparations that contained up to 5% whole cells. After centrifugation, the cytoplasts were collected from a middle quarter of the tube. The very fine uppermost band of dead cells was avoided. The lowest layer of cells + nucleoplasts was also collected, and after a 5× dilution with CMFH, fractions were pelleted (125*g* 10 min for cells, 275*g* 10 min for cytoplasts). Subsequent centrifugation for cells was at 80*g*, 10 min. Generally, 10×10^6 cells applied per gradient yielded 7.5×10^6 cytoplasts. For Feulgen staining, cells were fixed in 10% formalin in CMFH overnight, dried and ethanol-fixed onto slides, and stained by the Feulgen procedure. Cells were counterstained for 30 s in 0.5% Wool green (CI 44090, Aldrich) in 0.5% acetic acid, rinsed briefly in water, air dried, and mounted in balsam.

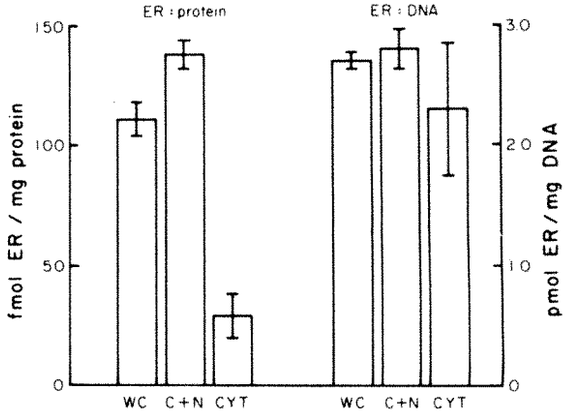

Fig. 2 Intracellular distribution of oestrogen receptor (ER). GH_3 cells were enucleated as described in the text. Oestrogen receptor, protein and DNA were measured in untreated density-selected whole cells (WC), in the cell + nucleoplast fraction (C + N), and in the cytoplast fraction (Cyt). In intact cells or cytoplasts, oestrogen receptor was measured as specific uptake of ^{3}H-oestradiol (151 Ci $mmol^{-1}$, NEN) 2 nM in culture medium + DNase (Worthington DPFF 50 μg ml^{-1}) after 30 min at 37 °C, with or without 200 nM nonradioactive oestradiol. Protein was measured with Coomassie blue staining[25] using the Bio-Rad microassay with bovine γ-globulin (Sigma) as the standard. DNA was measured using diphenylamine[26] or the fluorescent dye Hoechst 33258[27]. The figure shows the results of three separate experiments (error bar is the standard error) in which cytoplasts contained 4%, 2.5%, and 0.25% contaminating whole cells.

Table 1 Oestrogen receptor in enucleated cells

	Oestrogen receptor per mg protein (fmol)	Oestrogen receptor per mg DNA (pmol)	Protein per cell (pg)	DNA per mg protein (μg)	Oestrogen receptors per cell (molecules)
Whole cells	113	2.7	363	42	25,000
Cells + nucleoplasts	146	2.9	336	50	30,000
Cytoplasts	10	1.4	69	7.5	2,100*

One of the experiments of Fig. 3. Cytoplasts contained only 0.25% contaminating whole cells, by cell count with haemocytometer.

* As cytoplasts are approximately one-fifth the size of whole cells, by protein content, cytoplast receptors: cell equivalent was calculated as 5× the actual number of receptors per cytoplast.

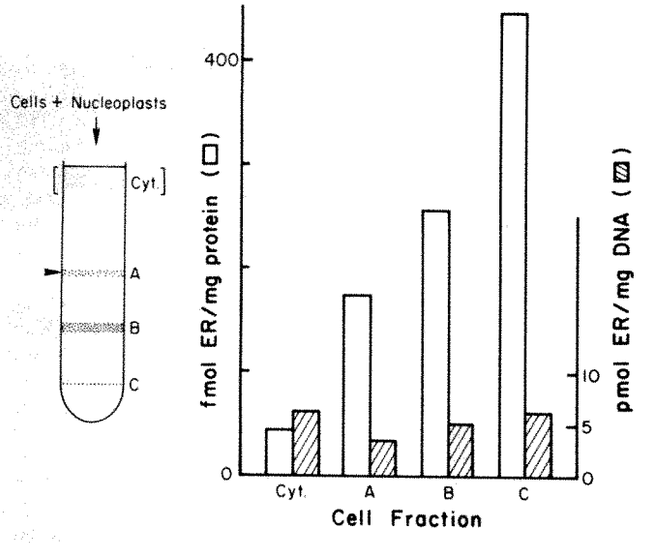

Fig. 3 After enucleation, the cytoplasts were saved separately while the cell+nucleoplast layer was further fractionated on a density step gradient, with Percoll at 1.04, 1.05, 1.07, 1.08 and 1.10 g ml^{-1}. After 20 min at 400*g*, cells were collected at interfaces between 1.05 to 1.07 g ml^{-1} (A), 1.07 to 1.08 g ml^{-1} (B), and 1.08 to 1.10 g ml^{-1} (C). The arrowhead at A indicates where the density-selected whole cells (1.058–1.063 g ml^{-1}) would have been found before enucleation, and the position that the cytoplasts would have occupied is indicated in brackets. Oestrogen receptor, DNA and protein were measured in each fraction. Of the cells+nucleoplasts that were recovered after fractionation by density, 15% were recovered at A (which includes the pre-enucleation density), 76% were recovered at B, and 9% were recovered at C.

since the majority of the cells appeared to contribute a cytoplast (Fig. 1). Furthermore, at least 85% of the cells increase in density after enucleation (Fig. 3 legend), which is consistent with this hypothesis.

Thus, the unfilled oestrogen receptor appears to be largely nuclear in the intact GH_3 cell. We propose that in the absence of steroid, the loose association of the receptor with the nuclear elements causes the receptor to partition into the cytosol when the cell is disrupted, and thus the cytosolic receptor represents an extraction artefact. This phenomenon may be limited to the GH_3 cell, but the similarity of the different steroid receptor systems suggests that these findings may be more broadly applicable. From our data and the literature cited above, we propose that in the intact cell, there is no nuclear translocation of receptor as part of the steroid response, but rather an increase in receptor affinity for nuclear elements.

We thank Rick Koch for technical assistance and Diane Mellon for help with the manuscript. Novel κ light-chain gene rearrangements in mouse λ light chain-producing B lymphocytes

Jeannine Durdik, Mark W. Moore & Erik Selsing

Rosenstiel Basic Medical Sciences Research Center and Department of Biology, Brandeis University, Waltham, Massachusetts 02254, USA

The genes that encode the immunoglobulin proteins made by B lymphocytes are made up of segments that are separately encoded in the germ-line genome and brought together by recombination during B-cell ontogeny[1]. There are two types of immunoglobulin light chain, κ and λ, but only a single type is expressed in individual B cells. It is thought that κ gene recombination precedes λ gene recombination during B-cell ontogeny[2,3]. We describe here unusual recombinations that have occurred in two λ-producing B-cell lines and suggest that they are involved in the developmental switch from κ to λ gene expression in maturing B cells. These recombinations involve the J_κ–C_κ introns of *V–J* joined but nonfunctional κ genes and a sequence that in the germ line occurs downstream of the C_κ exon (called RS, for recombining sequence).

We first detected κ DNA segments having unusual hybridization characteristics in Southern blot analyses[4] of two λ-producing cell lines, CH2 and MOPC315. In these cells, we found segments of DNA that hybridized with J_κ probes and intron probes but not with C_κ probes or probes representing sequences 5′ of the J_κ region (Fig. 1). These results indicated that J_κ-containing DNA segments in CH2 and MOPC315 had apparently undergone two recombinational events leading to the removal or replacement of DNA on both the 5′ and 3′ sides of the germ-line J_κ region. These recombinational events have resulted in J_κ regions having no associated C_κ exons in CH2 and MOPC315 cells. Indeed, both CH2 and MOPC315 have no C_κ exons within their genomes (Fig. 1); this is often the case in λ-producing cell lines[2,5,6].

We isolated and sequenced portions of the unusual J_κ-containing DNA segments from CH2 and MOPC315 cells to determine their structures (Fig. 2). Our data show that the two recombinational events generating the unusual DNAs in CH2 and MOPC315 have occurred within the J_κ locus and within the J_κ–C_κ intron. The J_κ-associated recombinations in CH2 and MOPC315 cells represent *V–J* joining events similar to those observed in all immunoglobulin-producing B cells (sequence data not shown). Alignment of the DNA sequences, using the invariant amino acid positions of mouse V_κ proteins[7] and the DNA sequences of the germ-line J_κ locus[8], shows that these *V–J* joining events are nonfunctional due to misalignments and frameshifts similar to others observed in several recombined antibody genes[9–11]. On the other hand, the J_κ–C_κ intron-associated recombinations that we find in the M315-rs1 and CH2-rs3 clones (Fig. 2) do not resemble any previously reported immunoglobulin gene recombinations. It is striking that our restriction map and sequence data indicate that the recombined

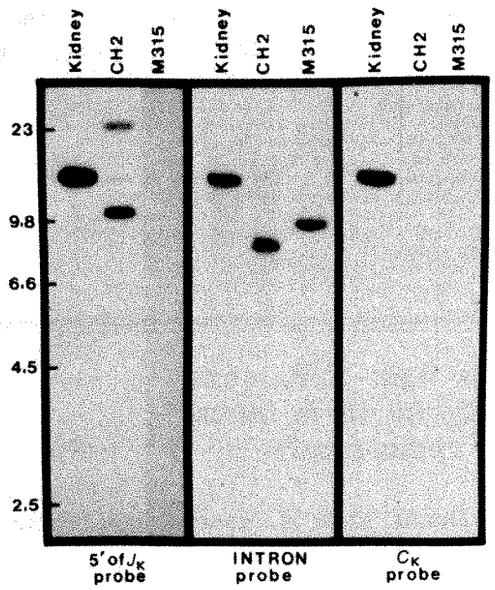

Fig. 1 Recombination of κ-gene DNA in CH2 and MOPC315 myelomas. Southern blots of ~30 μg of the indicated genomic DNAs, digested with *Bam*HI, were hybridized with the probes indicated. The probes are described in Fig. 2. Sizes of marker λ phage *Hin*dIII restriction fragments are indicated. RS DNA recombinations are detected as DNA fragments that hybridize with intron probes (and with J_κ probes, not shown) but not with C_κ probes or probes 5′ of J_κ. The DNA fragments in CH2 cells that are detected by 5′ of J_κ probes but not by intron or C_κ probes have been reported previously[21]. These DNA fragments seem to be related to κ gene *V–J* joining and will be described in detail elsewhere (E.S., J. Voss and U. Storb, in preparation).

RS DNA segments in CH2 and MOPC315 cells are identical. Our sequences also localize the joining sites for the intron-associated RS DNA recombinational events in rs3 and rs1 to within three nucleotides of each other (Fig. 2).

Because the recombined RS DNA segments found in CH2 and MOPC315 cells seem identical, we prepared unique hybridization probes for RS sequences from our rs1 and rs3 clones to ascertain the status of RS DNA in other cell lines. Figure 3 shows that RS sequences appear to be present in one copy per haploid genome in normal mouse kidney cells as judged by the intensity of a single germ-line hybridization band. In various murine B-cell tumour lines, however, RS DNA is often recombined (Fig. 3). In some cell lines, only a recombined RS segment is observed, reinforcing the notion that RS DNA is a single-copy DNA segment. In total, we found RS recombinations in four of six κ-producing plasmacytomas tested and also in all five λ-producing cell lines screened (see Fig. 3 legend). Of the 10 recombined RS segments that we observed in B-cell tumours, only the two in CH2 and MOPC315 hybridized with J_κ or intron probes (Fig. 1) indicating that many RS recombinations apparently involve sequences other than the J_κ–C_κ region. No RS recombinations were present in 12 T-cell tumour lines (data not shown). When we screened antibody-producing hybridomas we found that, in 14 κ-producing hybrids, only the recombined RS sequences contributed by the myeloma parent were present; no recombined RS DNA segments from the normal B-cell partner were detected (data not shown). In contrast, out of 10 λ-producing hybridomas, 8 displayed one or more recombined RS sequences apparently coming from the normal B-cell fusion partner (Fig. 3). We discuss the contrasting data from the normal and transformed B cells below; the results from the hybridomas, however, indicate that RS recombination is frequently linked to λ light-chain gene expression.

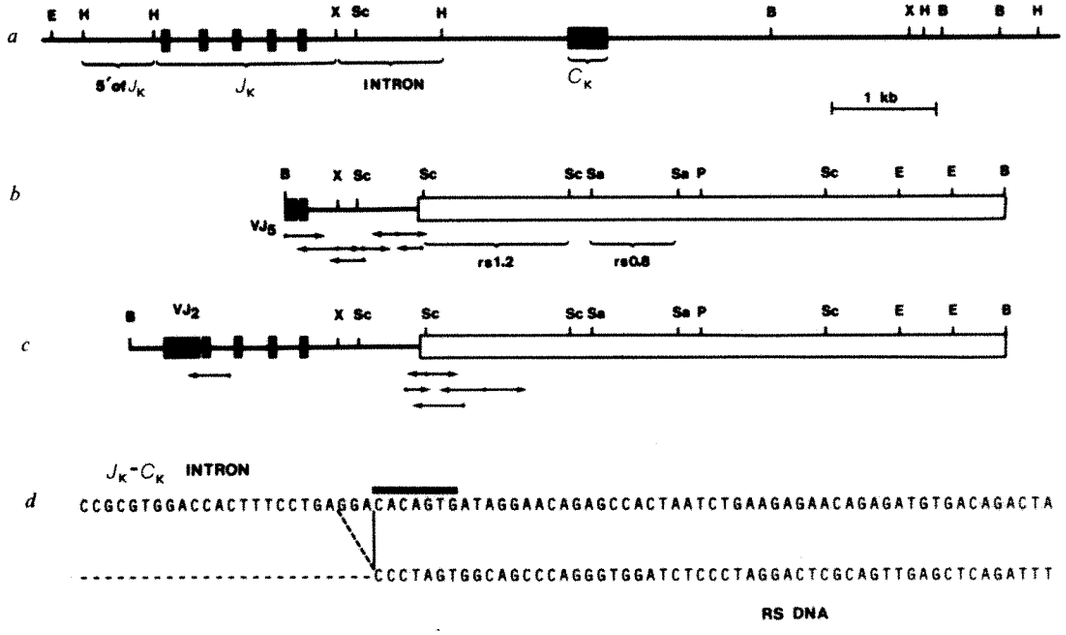

Fig. 2 Restriction enzyme maps of RS DNA clones. Restriction sites within the germ-line J_κ–C_κ locus and hybridization probes that were used to detect RS DNA recombination in MOPC315 and CH2 cells are shown in *a*. *b* And *c* show restriction maps of recombined RS DNAs (CH2-rs3 and M315-rs1) in CH2 and MOPC315 cells, respectively. Segments of rs3 and rs1 that comprise V_κ and J_κ sequences are indicated as lines or solid bars. Portions of rs3 and rs1 that derive from RS DNA are indicated as open bars. The positions of the rs1.2 and rs0.8 probes are also indicated. Chain termination DNA sequence analyses[22] of rs3 and rs1 *Sau*3A, *Hae*III or *Bam*HI, *Xba*I restriction fragments using M13 sequencing vectors[23] are indicated by arrows in *b* and *c*. All maps are drawn to scale and aligned at the *Xba*I site within the J_κ–C_κ intron. Restriction enzymes are: *Eco*RI (E), *Hin*dIII (H), *Xba*I (X), *Sac*I (Sc), *Sau*3A (Sa) and *Bam*HI (B). No *Hin*dIII sites are present in CH2-rs3 or M315-rs1. Not all *Sau*3A sites have been mapped in the rs3 and rs1 clones. *d* Shows nucleotide sequences surrounding the RS DNA recombination sites in rs3 and rs1. The diagonal dashed line represents RS recombination in CH2; the vertical solid line is RS recombination in MOPC315. An immunoglobulin recognition site heptamer, localized near CH2 and MOPC315 RS DNA recombination sites within the germ-line J_κ–C_κ intron region[8,14], is indicated by a heavy bar. Our J_κ–C_κ intron sequence differs at a few positions from that reported by Max *et al.*[8]; we find the same sequences in the rs3 and rs1 clones and presume that the previous sequence is in error. The horizontal dashes represent sequences 5′ of unrecombined RS DNA; these have not yet been determined.

Sequences near the sites of RS DNA recombination in CH2 and MOPC315 demonstrate an intriguing feature. In the J_κ–C_κ intron segment of DNA which is replaced by RS sequences, an immunoglobulin recognition site heptamer is present (Fig. 2). This heptamer represents one portion of the bipartite conserved recognition sequences that are found next to immunoglobulin V, D and J segments and that have been proposed to be binding sites for proteins involved in V–J and V–D–J antibody gene recombination[12,13]. Thus, the RS DNA recombinations in CH2 and MOPC315 bear a remarkable resemblance to the immunoglobulin gene recombinations that occur in normal differentiating B cells. This suggests that some enzymatic activities involved in normal B-cell antibody gene recombination could also have a role in RS DNA recombination. The recognition site heptamer located near RS DNA recombinations in CH2 and MOPC315 has previously been shown to be involved in an aberrant V_κ–C_κ recombination event in the myeloma, MPC11 (ref. 14).

Using Chinese hamster–mouse fusion cell lines, we have localized RS sequences to chromosome 6 in the mouse (J.D., D. Pravtcheva, F. Ruddle and E.S., unpublished). The structures of CH2-rs3 and M315-rs1 (Fig. 2) suggest that RS DNA may lie downstream of the C_κ exon on chromosome 6 and that the V_κ–J_κ–RS recombinations in CH2 and MOPC315 cells have resulted in deletions of C_κ (Fig. 1). Using various probes we can detect no homology between our RS DNA clones and a germ-line J_κ–C_κ clone (Charon 4A·Sp101) described previously[15]. Thus, RS sequences seem to be localized more than 10 kilobases (kb) downstream of the C_κ exon.

It is unknown which sequences recombine with RS in those cell lines where RS recombination does not involve the J_κ–C_κ intron. However, because, the RS recombinations in CH2 and MOPC315 cells involve a DNA sequence that resembles an immunoglobulin gene recognition site, it is possible that some RS DNA recombinations represent joining with V_κ genes. If RS sequences are downstream of the C_κ exon then such putative V_κ–RS recombinations would presumably also result in the deletion of C_κ (and J_κ) regions. These observations suggest that we have detected, for the first time, the molecular events responsible for the deletions of C_κ and J_κ exons that have frequently been observed in mouse λ-producing myelomas[5,6]. It will be interesting to determine whether sequences similar to RS are found in human cells because human λ-producing B-cell lymphomas also commonly have lost the J_κ–C_κ region[2].

Do the RS DNA recombinations that we have found have functional significance during B-cell ontogeny? The apparent lack of RS recombinations in two λ-producing hybridomas (Fig. 3), although possibly due to chromosomal loss during the cell fusion and selection process, does indicate that recombined RS segments are not essential for continued λ-chain production in cells that have functional, V–J joined λ genes. It could be that RS recombinations specifically act as mechanisms to remove C_κ regions from the genomes of B lymphocytes. It has been suggested that C_κ deletion might serve to remove nonfunctional V–J joined κ genes from the genomes of B lymphocytes and thus eliminate aberrant transcripts and prevent the synthesis of incomplete light chains[16]. Alternatively, RS recombination might have a positive role in B-cell differentiation. The structures of CH2-rs3 and M315-rs1 place RS DNA directly downstream from potentially active immunoglobulin gene promoters associated with recombined V_κ regions[17,18]. The putative V_κ-RS recombinations mentioned above would also exhibit structures with RS downstream from V_κ gene promoters. It is possible that RS DNA contains a gene that could be transcriptionally activated by recombination. Our finding of RS recombinations only in λ-producing hybridomas and not in κ-producing hybridomas suggests that such a gene might be involved in a switch from κ recombination to λ recombination in maturing B lymphocytes. In this model, C_κ exon deletion would be a side effect of RS recombination events.

We have sequenced ~900 base pairs of RS DNA adjacent to the recombination site in M315-rs1 (see Fig. 2). Within this sequence there are several short potential protein-encoding

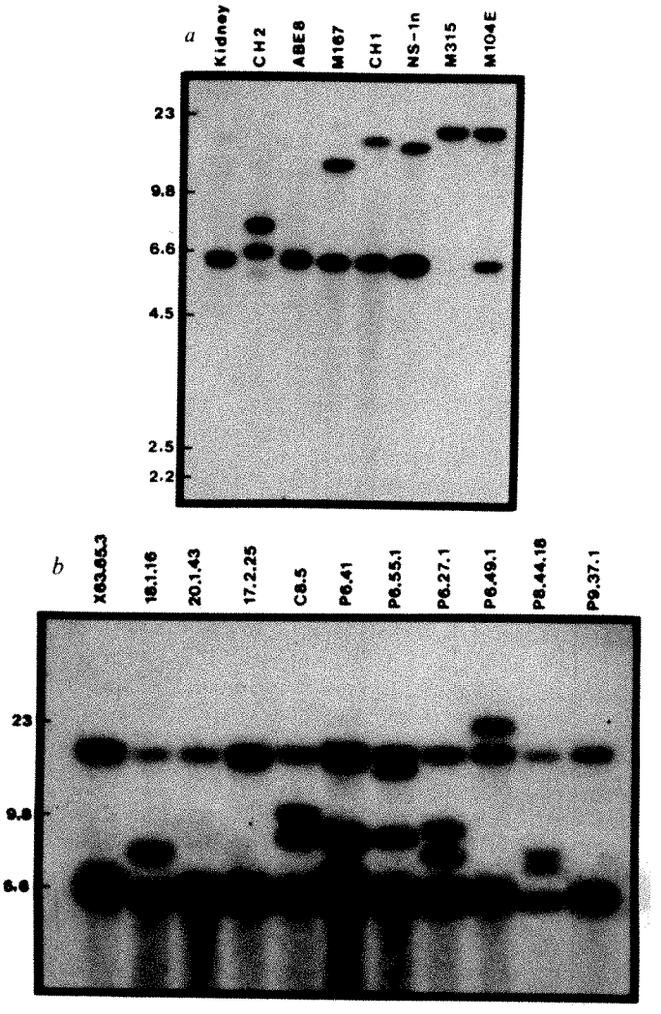

Fig. 3 RS recombination in B-cell lines. *Eco*RI-digested genomic DNAs were probed with the rs0.8 fragment (see Fig. 2). In *a*, recombined RS segments are seen in the κ-producing myelomas, MOPC167 (Litton) and NS-1n[20]; in the λ-producing myelomas, MOPC315 and MOPC104E (Litton); and in the λ-producing B lymphomas, CH1 and CH2 (ref. 24). In the Abelson murine leukaemia virus-transformed cell line, ABE8 (ref. 25), only a germ-line RS segment is evident. In other experiments we have detected recombined RS segments in the κ-producing myelomas MOPC511, MOPC321 and MOPC21 (Litton) and in the λ-producing myeloma, S178 (Litton). Only germ-line RS segments were found in the κ-producing myelomas, MOPC41 and J606 (Litton). In the 12 T-cell lines, SL1-SL9 (ref. 26), BALENTL-5 (Litton), EL-4 and YAC-1 (Salk), we found only germ-line RS segments. In *b*, recombined RS segments are seen in 8 of 10 anti-NP λ-producing hybridomas (ref. 27 and M. Borsch-Supan and T. Imanishi-Kari, unpublished) compared with the myeloma partner (X63.65.3) used in the cell fusions. In the hybridoma, 17.2.25, a recombined RS band at ~13 kb can be resolved from the X63.65.3 parental RS band in the original autoradiogram. An analogous experiment with 14 κ-producing hybridomas showed no recombined RS segments other than those from the myeloma fusion partner. κ Hybridomas included the six anti-PC hybridomas, 101.3C2.1, 101.3G8.4, 101.6G6.2, 100.6F9.1, 137.5G6 (ref. 28) and HP16 (ref. 29) and eight anti-(T,G,A)-L hybridomas (J. Press, unpublished).

open reading frames (40–80 amino acids long) but no clearly relevant RNA transcription or processing signals. We have not yet found any RNA transcription products from recombined RS segments using Northern blots of MOPC315 poly(A)$^+$ RNA hybridized with the rs0.8 and rs1.2 probes shown in Fig. 2 (J.D., S. Ogden, U. Storb and E.S., unpublished). To rule out a potential role of RS transcription in λ gene recombination, however, it will be necessary to probe cells actually undergoing immunoglobulin gene recombination.

The RS DNA recombinations that we observe in four κ-producing myelomas do not seem to be consistent with a regulatory role for RS in λ gene recombination. However, in two of these κ-producing myelomas (MOPC511 and MOPC21) recombined λ genes are also found (ref. 19 and our unpublished results). In addition, RS recombination may not be completely repressed in myeloma cells. In support of this notion, we find different RS DNA recombination products in the myeloma, MOPC21, and in a tissue culture variant, NS-1n, derived from MOPC21 myeloma cells[20]. Southern blots of MOPC21 DNA digested with *Eco*RI show a recombined RS band at 12.5 kb and an intense germ-line RS band at 6.5 kb. NS-1n, on the other hand, has a recombined RS band at 13.5 kb together with a germ-line 6.5-kb band. It is possible that a chromosomal loss of one recombined RS segment and a separate RS recombination on a different chromosome may have occurred during the generation of the NS-1n variant. Thus, RS recombinations may not be stable in myelomas maintained for long periods by serial passage. We believe, therefore, that it would be premature to discount a role for RS in controlling λ gene recombination on the basis of two κ-producing tumours.

Apparently, we have discovered molecular recombination events involved in the C_κ-deletion phenomenon commonly observed in λ-producing B lymphocytes. Our results raise the possibility that these recombination events have an active role in switching from κ to λ recombination in B-cell precursors. Clearly, further studies will be required to ascertain the relationships between RS recombination and the normal processes of immunoglobulin gene recombination in developing B lymphocytes.

A variant translocation places the λ immunoglobulin genes 3′ to the c-*myc* oncogene in Burkitt's lymphor

G. F. Hollis, K. F. Mitchell, J. Battey, H. Potter, R. Taub, G. M. Lenoir* & P. Leder

Department of Genetics, Harvard Medical School, Boston, Massachusetts 02115, USA
* International Agency for Research on Cancer, Lyon, France

Most translocations that occur in Burkitt's lymphoma[1,2] inv movement of part of chromosome 8, containing the c-*myc* g from its normal position to the immunoglobulin heavy-c locus on chromosome 14[3–7]. The genes are often joined at 5′ ends in opposite transcriptional directions[4–13]. Howev significant minority of Burkitt translocations[8] involve the l chain loci on chromosome 2 (κ)[14] or 22 (λ)[15]. We characterized one of these from a European-derived cell (IARC-BL37) that carries an 8;22 translocation. Here translocation has joined the 5′ portion of the λ light-chain l to the 3′ portion of the c-*myc* gene at a position about 7 kilol from the normal c-*myc* promoters. The translocatio reciprocal and relatively conservative, involving the loss of 21 base pairs from the site of recombination. This transloc allows us to orient the λ genes with respect to the centro of chromosome 22 and to predict the orientation of c translocations involving these chromosomal segments. Tl translocation is accompanied by an increased level of c- transcripts, especially that derived from a normally under- c-*myc* promoter.

The Burkitt's lymphoma line BL37 is a European-der Epstein–Barr virus (EBV) positive cell line that carries a 22 translocation and produces immunoglobulin μ and κ ch In our hands, this line is the only one for which the previ described correlation between type of translocation and l chain expression[8] is not observed, and the first line with t 22 translocation to show a detectable rearranged c-*myc* Comparison of *Eco*RI restriction fragments derived fron genomic DNA of the Burkitt cells with those from normal t (Fig. 1, lanes 1, 2) showed that both tissues contain a kilobase (kb) *Eco*RI fragment corresponding to the germ c-*myc* gene. The Burkitt cell contained an additional fragi 19.5 kb in length, presumably corresponding to the rearra c-*myc* gene. If this rearranged fragment contains the imm globulin λ light-chain genes[16], as suggested by the fact tha translocation involves chromosome 22, we might further e to find a correspondingly rearranged *Eco*RI fragment of that hybridizes with a probe derived from the λ constant re The relevant experiment is also shown in Fig. 1 (lanes 3, which a λ constant region probe detects a single rearra fragment, also 19.5 kb in length, in addition to the normal l at 5, 8, 14 and 16 kb. (The 5 kb *Eco*RI fragment seen i middle lanes corresponds to a processed λ pseudogene unl to the λ locus[17].) Note that these λ *Eco*RI fragments mai their germ-line configuration, as would be expected κ-producing B cell[18,19].

These data suggest that the c-*myc* and the immunoglo λ gene sequences now exist on a 19.5 kb *Eco*RI fragme DNA. While any of the six λ genes represented in this hapl could have been involved in this rearrangement, syste studies (data not shown) with uniquely hybridizing p derived from the flanking sequences 5′ to the first three λ suggested that the rearrangement occurred 5′ to the λ_1 (see Fig. 1). Evidence that the recombination betwee chromosomes is a reciprocal event was obtained using a from the region 5′ to the cross-over point of recombin (Fig. 1). The experiment is shown in the lanes 5 and 6 of

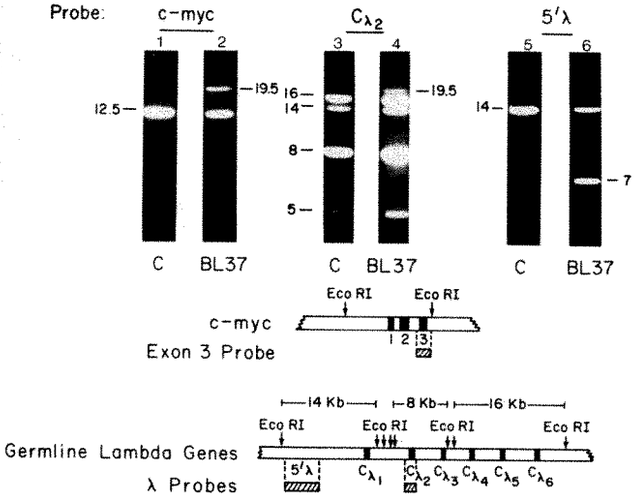

Fig. 1 The arrangement of c-*myc* and immunoglobulin λ gene segments in normal cells and the Burkitt's lymphoma BL37. Southern transfers[20] of *Eco*RI-digested genomic DNAs (10 μg per lane) from normal human white blood cells, C, and a Burkitt's lymphoma cell line containing a t(8; 22), BL37, were hybridized to ^{32}P-labelled DNA probes corresponding to exon 3 (*Cla*I–*Eco*RI) of the human c-*myc* gene (lanes 1, 2), human λ constant region 2 (*Bam*HI–*Bam*HI) (lanes 3, 4), and 5′ flanking region of λ constant region 1 (*Eco*RI–*Hin*dIII) (lanes 5, 6). The probe locations used are shown in the diagram. The transfers were washed in 0.1×SSC, 0.1% SDS at 52 °C and visualized by autoradiography. In addition to the 12.5-kb germ-line *Eco*RI band, the c-*myc* probe identifies a 19.5 kb band in the BL37. The λ constant region 1 probe identifies a non-germ-line 19.5 kb *Eco*RI fragment, as well as the 5, 8, 14 and 16 germ-line bands. The 19.5 kb and 7 kb non-germ-line *Eco*RI fragments were cloned into the λ vector Charon 4A (ref. 20) using the exon 3 c-*myc* probe and 5′ flanking λ probe respectively.

and the appearance of the expected 7 kb reciprocal recombination product in the lane 6 indicates that the cross-over point lies between this 5′ probe and the λ_1 gene. Both rearranged fragments were isolated by preparative gel electrophoresis and cloned in the λ phage vector Charon 4A[20].

The orientation of the two genes and the cross-over point of their recombination was established by comparing their structures with those of known germ-line c-*myc* and immunoglobulin genes[9,16] by both heteroduplex mapping and restriction fragment map comparison. The heteroduplex structure shown in Fig. 2*a* was formed between the cloned 19.5-kb *Eco*RI fragment containing the rearranged c-*myc* gene and the germ-line c-*myc* gene. The structure has a 12.5-kb region of homology (representing virtually the entire 12.5-kb *Eco*RI germ-line DNA c-*myc* segment, see map) and a single-stranded substitution loop approximately 7 kb in length. The position of the substitution loop indicates that rearrangement has occurred 3′ to the c-*myc* gene. When the same rearranged fragment is hybridized to a germ-line fragment of DNA derived from the λ_1 gene (maps in Figs 1, 2), a 7 kb length of homology is seen, as are two single-stranded regions of non-homology, 7.0 and 12.5 kb in length (Fig. 2*b*). Comparison of subclones derived from the cross-over region from the two germ-line genes and the products of their reciprocal recombination showed that the 12.5-kb portion of the 19.5 kb rearranged fragment has a restriction map identical to that of the germ-line c-*myc* gene and is then identical for 7 kb to the λ_{C1} immunoglobulin fragment (data not shown).

The orientation and breakpoints were finally established by determining the nucleotide sequence of the cross-over region in its germ line and rearranged configurations and the sequence of the cross-over region is shown in Fig. 3. With the exception of a 21 base pair (bp) segment of DNA derived from the λ_1 germ-line locus which is missing from the recombinants, the sequences at the breakpoints are entirely conserved over the sequenced regions. The data are all consistent with a translocation between a position 400 bases 3′ to the poly(A) addition site of the *myc* gene and a point 5 kb 5′ of the sequence

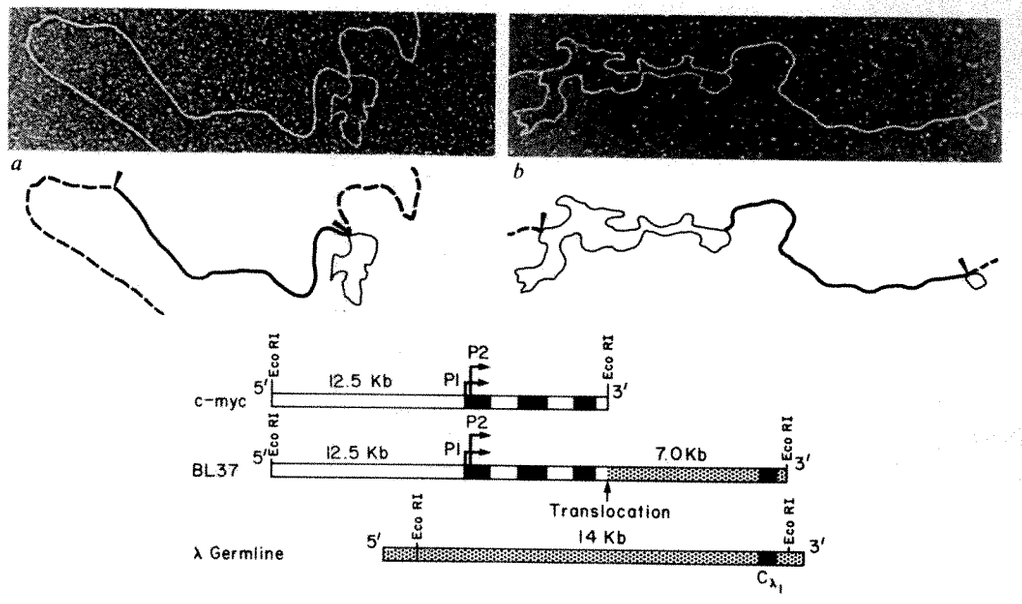

Fig. 2 Heteroduplex comparison of the rearranged c-*myc* gene derived from BL37 and germ-line c-*myc* and immunoglobulin λ genes. *a*, A recombinant phage clone containing the 19.5 kb *Eco*RI restriction fragment identified in Fig. 1 was heteroduplexed to a recombinant phage containing the 12.5 kb *Eco*RI c-*myc* fragment using alkali denaturation followed by renaturation in 50% formamide, 12.5 mM EDTA, 50 mM NaCl and 100 mM Tris *p*H 8.5 at 37 °C for 15 min. In addition to the heteroduplex formed between the vector phage arms, there is a region of homology (see arrows in graphic) that corresponds to nearly the entire 12.5 kb *Eco*RI c-*myc* DNA fragment. At a position 3′ to the c-*myc* gene a 7 kb region of non-homology is seen. This heteroduplex structure is consistent with the 19.5-kb recombinant DNA phage clone containing nearly all of the 12.5 kb *Eco*RI fragment, including the three exons of c-*myc* that are normally located on chromosome 8. The structures of this 19.5 kb clone as well as the germ-line c-*myc* fragment are shown schematically. *b*, The phage containing the rearranged 19.5 kb *Eco*RI fragment BL37 was heteroduplexed to a phage containing a 15 kb segment of DNA that encodes the λ_1 gene that was derived from human fetal liver. The latter clone includes the 14 kb *Eco*RI fragment carrying λ constant region 1 as shown in the map. In this heteroduplex, a 7 kb homology is seen, as well as two single-stranded regions 12.5 kb and 7.0 kb in size. The position of the homology in this heteroduplex indicates that this library clone and the 19.5 kb clone share sequence homology for 7 kb 5′ to λ constant region 1. The two clones diverge at this point, the region where the 19.5 kb clone carries sequence from the c-*myc* locus of chromosome 8. A small region of non-homology is seen (see arrow to the right), which corresponds to the distance the library clone extends 3′ to the *Eco*RI site. These results are shown schematically.

Fig. 3 Sequences of the regions involved in the 8; 22 translocations in BL37 were determined by dideoxy sequence analysis[26]. Four aligned sequences are shown, each of which represents the DNA strand which bears the coding sequences of the genes. The upper sequence represents germ-line chromosome 8. The second sequence is the recombinant which bears the *myc* and λ genes. The third sequence is the reciprocal translocated product and the fourth sequence represents the germ-line chromosome 22. The 21 bases deleted in the translocation event are indicated separated from the adjacent sequence. The CCAAACCC sequence described in the text is boxed with a solid line and the YAGGTTG sequence boxed with a dashed line.

that has been identified as the J region of λ_{C1} (N. Berliner, unpublished).

In the other translocations investigated thus far, the c-*myc* gene is often joined to one of the heavy-chain switch region signals[4–6,9–13]. It is, therefore, attractive to think that the switch recombination system catalyses the Burkitt-type translocation. Analysis of the structure of the cross-over point of the BL37 translocation has allowed us to compare the structure of the substrates and products of the recombination event. Several hundred nucleotides of sequence in this region from both germline c-*myc* and immunoglobulin genes have been examined and extensive regions of switch-like homology have not been found. Therefore, the situation in the BL37 cell line, in which neither partner provides an extensive switch signal, makes such a mechanism less likely. It is, therefore, worth noting that the sequence, YAGGTTG, which has been found 8–16 nucleotides 5′ of many normal heavy-chain switching events[21], occurs in 6/7 consensus form 11 bases away from one of the breakpoints on chromosome 22. This sequence does not appear in the products of the translocation since it occurs within the 21 bp segment that is deleted (Fig. 3). Also, an octanucleotide, CCAAACCC, occurs very close to the cross-over point in the c-*myc* (chromosome 8) segment (Fig. 3). This sequence also flanks the recombination site in the translocation that occurs 5′ to the c-*myc* gene in the Burkitt line BL22[9]. We note that a sequence which differs by only a single base from this is present in reverse complement form adjacent to the breakpoint in a murine plasmacytoma reported recently[22]. It will require the characterization of further examples before we will be able to evaluate the significance of these observations.

One clue to a potentially important regulatory feature of the c-*myc* gene comes from comparative studies of its normal structure[9]. The c-*myc* gene is encoded in three exons, the first of which is a 550 bp untranslatable leader sequence that is tightly conserved in sequence between mouse and human species. This region encodes two promoter sequences that define two transcription initiation sites about 160 bp from one another (map,

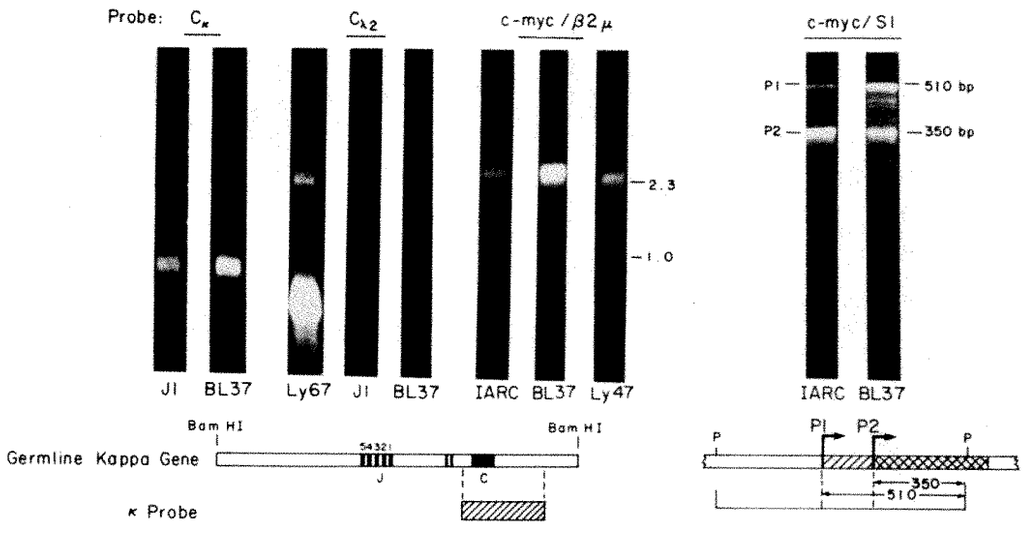

Fig. 4 Comparative analysis of the mRNA derived from BL37 and other Burkitt's lymphoma and lymphoblastoid cell lines. Total RNA was made[27] from Burkitt's lymphomas BL37, J1, Ly67 and Ly47 and the lymphoblastoid cell line IARC 100 and used for RNA blotting and S_1 nuclease analysis. RNA blots[28] from Burkitt's lymphomas J1 and BL37, both κ light-chain producers, were probed with a DNA (*Eco*RI–*Eco*RI) probe containing the κ constant region sequence. RNA from both cell lines hybridized specifically to give one band on the blot (see C_k probe). When J1 and BL37 RNA, as well as RNA from a λ-producing Burkitt's lymphoma, Ly67, was probed with a λ constant region, only the RNA from the Ly67 hybridized to the probe (see $C_{\lambda 2}$ probe). Transcription of the c-*myc* gene was determined in BL37 as well as IARC-100 and Burkitt's lymphoma Ly47, a λ producer, by probing with the second coding exon of c-*myc* (see Fig. 1). All three cell lines produce a 2.3 kb c-*myc* specific RNA, but the amount of c-*myc* RNA in BL37 appears higher than in IARC 100 (see c-*myc* probe). To control for the amount of RNA loaded in each lane, the same RNA blot was rehybridized with a β_2-microglobulin probe[29]. All three cell lines produce a 1.0 kb β_2-microglobulin specific RNA. By using the β_2-microglobulin specific hybridization as a control for RNA concentration, densitometric scans showed that BL37 produces 15-fold more c-*myc* RNA than IARC 100. To determine the point of initiation of transcription of the c-*myc* gene in BL37, an 860-bp *Pvu*II–*Pvu*II M13 mp9 clone containing the two promoters of transcription was labelled *in vitro* with ^{32}P-dATP by primer extension[9]. The single-stranded probe was allowed to anneal to 10 μg of tRNA and 10 μg of total RNA from BL37 and IARC 100 and then digested by 750 units of S_1 nuclease essentially as described by Berk and Sharp[23]. The digestion products were electrophoresed on an 8 M urea 5% acrylamide and visualized by autoradiography (see c-*myc*/S1), tRNA alone showed no protection of the probe (data not shown).

Fig. 4). Studies carried out in EBV-immortalized lymphoblastoid cell lines and non-transformed fibroblasts indicate that products derived from the use of the second promoter, P_2 (Fig. 4), are consistently represented among the stable c-*myc* transcripts of these cells at a higher level than transcripts derived from the first promoter, P_1. The fixed, approximately fourfold excess of P_2 transcripts in untransformed cells suggests the existence of a regulatory programme that maintains this ratio[24].

With these features in mind, we have used RNA blot hybridization to examine the immunoglobulin light chain and c-*myc* transcripts in several Burkitt's lymphoma cell lines including BL37 and a lymphoblastoid cell line. The results are shown in Fig. 4. The first two sets of panels in Fig. 4 show that the BL37 cell line produces large amounts of κ mRNA, but only trace amounts of λ RNA. Control Burkitt cell lines that produce only κ (J1) and only λ (Ly67) mRNAs are shown for comparison. The third set of three panels compares the c-*myc* transcript present in a lymphoblastoid cell line (IARC-100) with that in the BL37 cell line and another Burkitt cell line, IARC-Ly47. The level of β_2-microglobulin mRNA is determined in each cell line to control for the amount of mRNA added to each lane. Although the amount of β_2-microglobulin is approximately equivalent in each lane, the level of c-*myc* transcript is about 15-fold higher in the BL37 cell line. In contrast, the c-*myc* RNA is only slightly increased (1.4-fold) in the Burkitt line Ly47 when compared with the non-malignant IARC-100 cell line.

A more revealing analysis is one that distinguishes between the products of the two c-*myc* promoters. Such an experiment, carried out using the S_1 nuclease technique[23], is shown in lanes 9 and 10 of Fig. 4 (lanes c-*myc*/S1). As with other lymphoblastoid cell lines, the IARC-100 cell line has a predominant transcript that arises from the second promoter, P_2, which is represented in about fourfold excess over that which arises from the first promoter, P_1. In contrast, the two c-*myc* promoters P_1 and P_2 are both extensively used in BL37 indicating an activation of the *myc* gene in this cell line similar to that we have observed in other Burkitt-derived lines[24].

The orientation of the c-*myc* gene on chromosome 8 may be deduced from the data presented by Dalla-Favera *et al.*[25] to be centromere–(5′-c-*myc*-3′)–telomere. The genes on the recombinant chromosome in BL37 are arranged 5′-c-*myc*-3′-5′-λ1-3′ (tail-to-head). Since the breakpoint on chromosome 8 is 3′ to the c-*myc* gene, the gene itself must be associated with its original centromere in the recombinant chromosome. Therefore, the germ-line orientation of the λ genes is established by the structure of the translocation product and must be centromere-(5′-λ_1-3′)–telomere. Since all the λ genes are encoded on the same strand of DNA, one can predict that all simple translocations between chromosomes 8 and 22 will place the c-*myc* and λ immunoglobulin genes in a tail-to-head orientation. It is possible that some chromosomes will rearrange such that the λ gene will in fact be 5′ to the c-*myc* gene in a tail-to-head orientation and the *myc* gene could be affected by upstream λ gene promoters or enhancers.

We thank Ms T. Broderick and Ms A. Jacobs for assistance in the preparation of this manuscript, M. Vuillaume and C. Bonnardel for their technical assistance, E. I. duPont de Nemours and Co. and the American Business for Cancer Research Foundation for supporting portions of this work. Portions of this work was supported by NIH grant GM17088. Novel mannosidase inhibitor blocking conversion of high mannose to complex oligosaccharides

Ulrike Fuhrmann*, Ernst Bause†, Günter Legler† & Hidde Ploegh*§

Institute for *Genetics and †Biochemistry, University of Cologne, Weyertal 121, 5000 Cologne 41, FRG

Many secretory and membrane proteins are glycoproteins carrying asparagine-linked (*N*-linked) oligosaccharides. There are two types of *N*-linked glycans, referred to as high-mannose and complex type, respectively. Biosynthesis of *N*-linked glycans of the complex type proceeds via a high-mannose intermediate. After the initial transfer of a high-mannose oligosaccharide with the composition $(Glc)_3(Man)_9(GlcNAc)_2$ from a lipid carrier to the nascent polypeptide chain, trimming reactions take place. Trimming glucosidases remove the glucose residues quantitatively and mannosidases IA/B and II can remove all but three mannose residues. After trimming, terminal sugars such as *N*-acetylglucosamine, galactose, sialic acid and fucose may be added and result in the conversion to a glycan of the complex type[1]. Because suitable inhibitors were lacking, it was difficult to assess the importance of the trimming reactions for proper intracellular traffic, modification reactions other than the addition of terminal sugars, or as regulatory steps in glycoprotein processing. Here we describe the action of 1-deoxymannojirimycin (1,5-dideoxy-1,5-imino-D-mannitol, dMM; Fig. 1) on the biosynthesis of IgM and IgD. dMM is the mannose analogue of 1-deoxynojirimycin (dNM; Fig. 1), itself a glucosidase inhibitor[2–4]. We present evidence that dMM is a mannosidase inhibitor. *In vivo* dMM inhibits the equivalent of the mannosidase IA/B activities and blocks conversion of high-mannose to complex oligosaccharides. It is the first such inhibitor to be reported. Interference with the biosynthetic pathway of *N*-linked glycans could prove to be a powerful way to manipulate carbohydrate structure *in vivo*.

The experimental system consists of hybridoma cells producing IgM[5] and IgD[6] specific for the hapten (4-hydroxyl-3-nitrophenylacetyl, NP). After preincubation with inhibitor, these cells were pulse labelled for 10 min with ^{35}S-methionine and then chased with non-radioactive methionine in the continued presence of inhibitor. The inhibitors used were dMM and, for comparative reasons, the mannosidase II inhibitor swainsonine[7,8] (SW; Fig. 1). At different times of chase samples were taken and immunoglobulin was isolated from detergent lysates of cells (cytoplasmic immunoglobulin) or culture supernatants

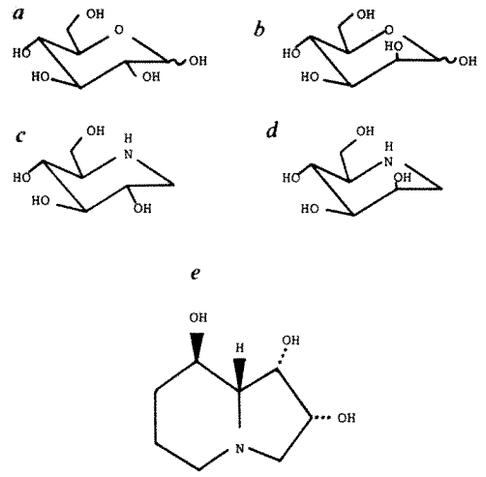

Fig. 1 Structures of glucose, *a*, mannose, *b*, the corresponding sugar analogues 1-deoxynojirimycin, *c* and 1-deoxymannojirimycin, *d* and the mannosidase II inhibitor[8] swainsonine, *e*.

(secretory immunoglobulin) by incubation with an affinity support (Fig. 2). For control cells and SW-treated cells the cytoplasmic immunoglobulin shows a steady decrease in apparent molecular weight (M_r) with time in pulse-chase experiments of this type[3,9], due to oligosaccharide trimming (Fig. 2*a*). On secretion an observed increase in M_r is caused by the addition of terminal sugars[9] (Fig. 2*a*). The M_r of cytoplasmic immunoglobulin from SW-treated and control cells is indistinguishable at each corresponding chase time as reported earlier[3]. Immunoglobulin from dMM-treated cells has a higher M_r than that from control cells, suggesting the inhibition of trimming reactions. In Fig. 2*b* these differences in M_r can be clearly demonstrated in a mixing experiment. dMM does not inhibit secretion of IgM or IgD (Fig. 3), as opposed to dNM which was shown to inhibit secretion of IgD but not IgM[3]. The analysis of IgD precursors is complicated by the fact that differentially *N*-glycosylated membrane and secretory IgD are present simultaneously[6,9]. This explains the multitude of δ-specific bands in Figs 2 and 3. In dMM-treated cells the secreted δ chains are indistinguishable in M_r from the middle two bands present in the cytoplasmic samples (Fig. 2*a*). Similarly, no difference in M_r was observed for secretory IgM and cytoplasmic IgM at 60 min in dMM-treated cells (Fig. 2*c*). It is possible that in the presence of dMM, terminal modifications can no longer occur because removal of mannose residues is incomplete. In SW-treated cells terminal modifications do take place, but to a lesser extent than in control cells, as evidenced by a lower M_r of secreted immunoglobulin. This observation is consistent with the inhibitory action of SW on mannosidase II which does not allow all oligosaccharide antennae to be terminally modified[3,10].

The results obtained with dMM suggest that no terminal modifications occur and that the target of dMM inhibition *in vivo* acts before that of SW. Such a situation would be consistent with inhibition of mannose removal, that is, inhibition of the mannosidase IA/B activity. If correct, a $(Man)_9(GlcNAc)_2$ structure, which is endoglycosidase H (EndoH) sensitive[11], would be expected to accumulate and be present on immunoglobulin secreted by dMM-treated cells. Therefore, no incorporation of terminal sugars such as galactose and sialic acid should occur. Moreover, the oligosaccharides should be of a size consistent with this hypothesis and should remain sensitive to EndoH. Therefore the following experiments were carried out.

IgM- and IgD-producing cells were mixed and preincubated with inhibitor for 4 h. These cells were then labelled with ^{3}H-galactose, and a small aliquot was labelled in parallel with ^{35}S-methionine. Immunoglobulin was prepared from the culture supernatants and analysed by SDS–polyacrylamide gel electrophoresis (PAGE). Secreted immunoglobulin from SW-treated and control cells was readily labelled with ^{3}H-galactose (Fig. 3*a*), whereas no label was incorporated into immuno-

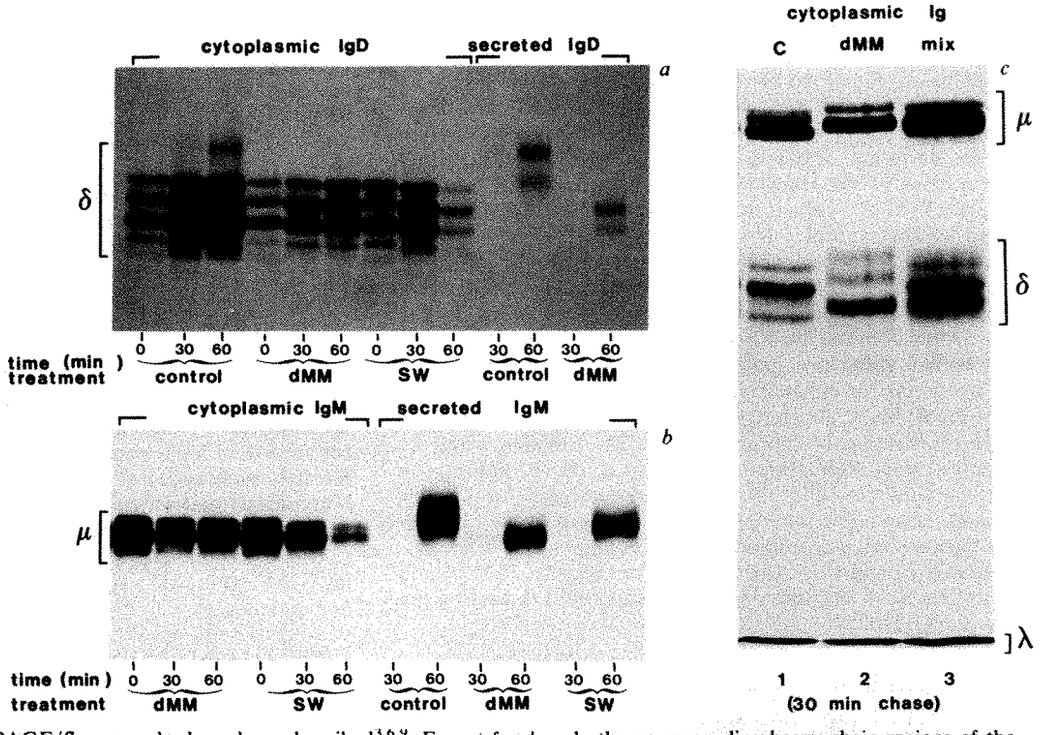

Fig. 2 Pulse-chase analysis of the biosynthesis of IgD (*a*, *b*) and IgM (*b*, *c*). Cells (6×10^6 per sample) were preincubated with inhibitor (dMM or SW, at 1 mM or 10 μg ml^{-1} respectively) for 1 h, pulse-labelled with 50 μCi of ^{35}S-methionine per sample and chased with non-radioactive methionine in the continued presence of inhibitor. SW was a gift of Drs Vosbeck and Elbein, dMM was a gift of Drs Kinast and Truscheit; a novel scheme for the synthesis of dMM has been developed and will be published elsewhere[15]. Samples were taken for isolation of immunoglobulin at the times indicated in the figure. Detailed procedures for labelling of cells isolation of NP-binding immunoglobulin on affinity matrices and analysis by SDS–PAGE/fluorography have been described[3,6,9]. Except for *b*, only the corresponding heavy chain regions of the autoradiograms are shown. Immunoglobulin was isolated or from detergent extracts of cells (cytoplasmic immunoglobulin) or from culture supernates (secreted immunoglobulin). C, control; dMM, 1-deoxymannojirimycin; SW, swainsonine. For *b*, approximately equal amounts of IgM and IgD biosynthetic precursors were mixed and co-electrophoresed. Cytoplasmic immunoglobulin for 30 min is shown for control cells (lane 1), dMM-treated cells (lane 2) and a mixture of the samples from lanes 1 and 2 (lane 3).

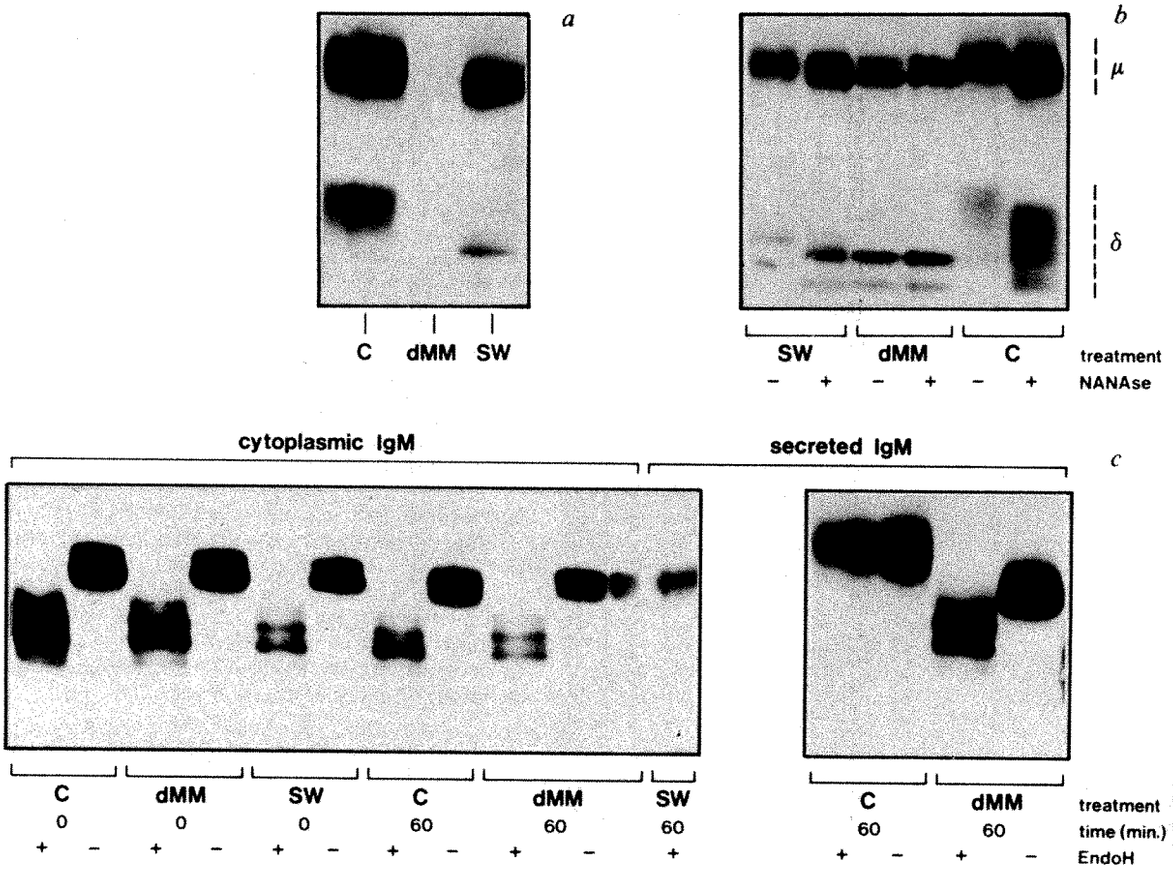

Fig. 3 Analysis of IgM and IgD biosynthesis by sugar labelling, neuraminidase and endoH treatment. *a*, A mixture of IgD- and IgM-producing cells (8×10^6 cells ml^{-1}, final volume 1.25 ml) were preincubated with dMM (1 mM) or SW (10 $\mu g\ ml^{-1}$) for 4 h. A 1-ml aliquot was then labelled with ^{3}H-galactose as described elsewhere[3]. Immunoglobulin was isolated from the culture supernatant and displayed by SDS–PAGE as in Fig. 2. *b*, The remainder of the cells (250 μl) were labelled with ^{35}S-methionine after transfer into methionine-free medium containing inhibitor. Immunoglobulin was isolated from the supernatant and analysed as in Fig. 2. Neuraminidase digests were prepared as described elsewhere[9] and were run on the same gel. *c*, Samples obtained from ^{35}S-methionine-labelled samples prepared as described in Fig. 2, were taken at the times indicated and digested with EndoH as described elsewhere[9].

globulin secreted by dMM-treated cells. Synthesis and secretion of immunoglobulin were not inhibited, as is evident from the ^{35}S-methionine labelling experiment carried out in parallel: similar quantities of immunoglobulin, as verified by quantitation of trichloroacetic acid precipitable material (data not shown) were secreted by SW-treated, dMM-treated and control cells (Fig. 3*b*). The ^{35}S-methionine-labelled samples were subjected to digestion with neuraminidase (NANAse). Removal of sialic acid residues is accompanied by a decrease in M_r (ref. 9), as is observed for both control and SW-treated samples. Immunoglobulin from dMM-treated cells was not susceptible to NANAse (Fig. 3*b*). Further proof of inhibition of conversion of high mannose to complex type oligosaccharides was derived from digestion with EndoH of ^{35}S-methionine-labelled samples. Cytoplasmic immunoglobulin precursors, regardless of time or treatment, were sensitive to EndoH (Fig. 3*c*). Immunoglobulin secreted by SW-treated and control cells was resistant to EndoH, whereas IgM secreted by dMM-treated cells was as sensitive to EndoH as cytoplasmic IgM (Fig. 3*c*).

Conclusive evidence for the inhibition of high mannose to complex type oligosaccharide conversion comes from the analysis of EndoH-released oligosaccharides, obtained from dMM-treated cells labelled with ^{14}C-mannose. After digestion of the labelled immunoglobulin with EndoH the size of the released oligosaccharides was determined by gel filtration in comparison with standards of known structure. The elution profile of these oligosaccharides on a Biogel P4 column, as well as that of marker oligosaccharides, is shown in Fig. 4. The major peak of EndoH-released IgM oligosaccharides (III, Fig. 4*b*) eluted at a position identical to that of a $(Man)_9(GlcNAc)$ marker (I, Fig. 4*a*). The absence of radioactivity in the void volume again indicates that all oligosaccharides on IgM from dMM-treated cells were fully susceptible to EndoH. Approximately one-quarter of the released oligosaccharides was found to elute at a position corresponding to that of $(Man)_8(GlcNAc)$ (IV, Fig. 4*b*), probably the consequence of incomplete inhibition of mannose removal in our experimental conditions. The peaks from the Biogel P4 column were recovered and analysed in parallel by TLC in conditions that allow resolution of the various oligosaccharides (Fig. 4*c*). The major peak (III) possessed an R_F identical to that of the $(Man)_9(GlcNAc)$ marker (II). The minor peak had a mobility consistent with a $(Man)_8(GlcNAc)$ structure (IV). Thus the combined data show that dMM treatment results in the retention of the high mannose configuration.

1-Deoxymannojirimycin is the first inhibitor to be described that inhibits *in vivo* conversion of high mannose to complex type oligosaccharides by blocking the equivalent of a mannosidase IA/B activity. Substances have now been identified that inhibit *in vivo* trimming glucosidases[3,4,12,13], mannosidase II[7,8], and, here, also mannosidase IA and/or IB. Earlier results obtained with tunicamycin[3,9] and 1-deoxynojirimycin[3] showed that elimination of *N*-linked glycosylation altogether or manipulation of glucosidase trimming may have different effects on secretion of immunoglobulin. However, we found no evidence for an inhibitory effect of dMM on secretion of IgM or IgD. The observation that dMM, the mannose analogue of dNM, itself a potent glucosidase inhibitor, is a mannosidase inhibitor suggests that the reaction mechanisms for trimming glucosidases and mannosidase reactions are similar. Both may be postulated to proceed through a cationic reaction intermediate[2].

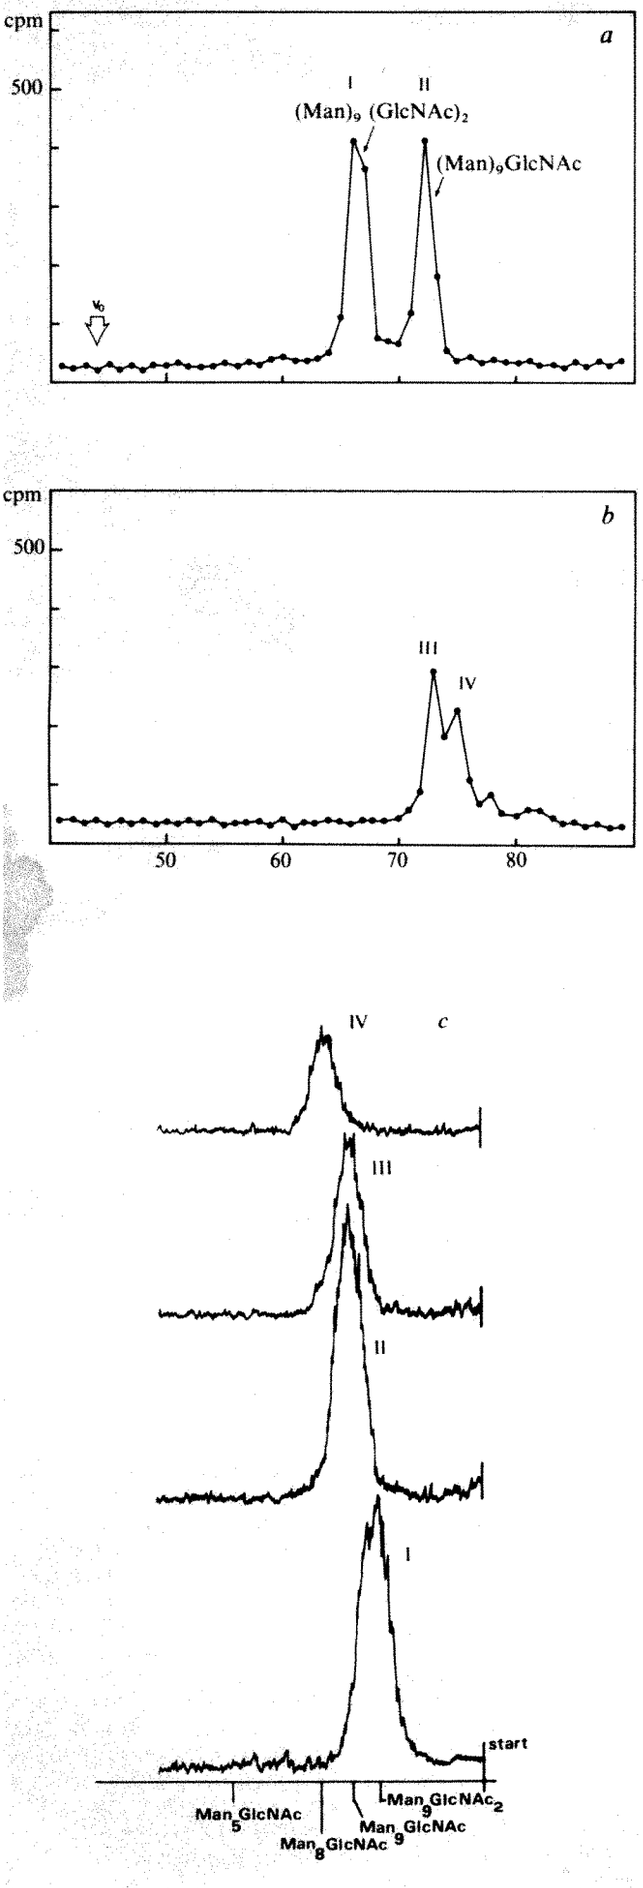

Fig. 4 Gel filtration of ^{14}C-mannose-labelled oligosaccharides obtained from IgM secreted by dMM-treated cells. IgM-producing cells were labelled with ^{14}C-mannose (50 μCi) for 8 h in the presence of 1 mM dMM. IgM was isolated from the culture supernatant as in Fig. 2 and digested with EndoH as described elsewhere[9] but with the inclusion of 0.1% SDS after 3 h digestion. The digest was applied directly to a Biogel P4 (200–400 mesh) column (180 × 1.2 cm) and eluted with 1 M acetic acid. Fractions of 1.32 ml were collected and 200 μl aliquots were counted by liquid scintillation counting. Recovery was better than 90%. The included volume of the column, as determined by chromatography of ^{14}C-glucose, was at fractions 98–102. The void volume is indicated by an open arrow. *a*, Elution profile of marker oligosaccharides $(Man)_9(GlcNAc)_2$, I, and $(Man)_9(GlcNAc)$, II, prepared as described elsewhere[4]. *b*, Elution profile of IgM-derived oligosaccharides after digestion with EndoH. *c*, TLC of: I (fractions 66–67); II (fractions 72–74); and IV (fractions 75–76) from *b* in silica gel. The plate was developed twice with *n*-propanol : acetic acid : water (3 : 3 : 2). Radioactivity profiles obtained by scanning are shown. Peaks II and III have identical R_F values ($(Man)_9(GlcNAc)$).

Carbohydrate moieties have been implicated in a variety of recognition phenomena, ranging from cellular aggregation[14] to participation in embryonic development and immune recognition. Such problems can now be addressed in a more refined manner by manipulation of carbohydrate structure through use of oligosaccharide trimming inhibitors.

A new myosin fragment: visualization of the regulatory domain

Donald A. Winkelmann, Sheri Almeda, Peter Vibert & Carolyn Cohen

Rosenstiel Center, Brandeis University, Waltham, Massachusetts 02254, USA

Many of the functional domains of the myosin molecule have been defined by the use of proteolytic enzymes. Major fragments that retain enzymatic or assembly properties have been prepared by cleavage in the rod to form heavy meromyosin (HMM) and light meromyosin (LMM)[1] or at the head–rod junction to form S-1 and rod[2,3]. Limited tryptic digestion of vertebrate skeletal myosin S-1[4] indicates that the head contains three major regions: an amino-terminal nucleotide binding domain of molecular weight (MW) 25,000[5,6], a central domain of MW 50,000 and a carboxyl domain MW 20,000; the latter two are both able to bind to actin[7,8]. Tryptic digestion of scallop S-1 has also been used to isolate a head fragment MW 14,000 associated with both types of scallop light chains[9]. Here we report that myosin from vertebrate (chicken and rabbit skeletal) and molluscan (scallop adductor) striated muscles is cleaved in an unusual way with an enzyme from *Pseudomonas aeruginosa*[10–12]. This bacterial protease (designated Ps-1) does not cleave myosin at the head–rod junction or in the rod;

© 1984 M

instead, Ps-1 splits the myosin heavy chain within the head, yielding a complete rod joined to the 20,000-MW head domains. The scallop regulatory and essential light chains remain associated with this fragment. We examined this new fragment by electron microscopy; the rods bear two 'nubs' about 100 Å long, which appear to correspond morphologically to the neck region of the myosin molecule[13,14].

In contrast to trypsin[1], chymotrypsin[3] or papain[2], Ps-1 cleaves myosin initially at the 75,000–20,000 junction in the head so that a new, larger rod fragment (MW 140,000) and a head fragment (MW 75,000) are produced (Fig. 1). The rod contains the complete rod heavy chain (MW 120,000) together with an additional 20,000-MW peptide derived from the head (Figs 2, 3). The reactive sulphydryls (SH-1 and SH-2)[15] are retained on this 140,000 fragment (data not shown). The associated myosin light chains also show limited cleavage by Ps-1: the two larger light chains (LC1 and LC2) of the vertebrate myosins and the regulatory light chain (RLC) of scallop myosin each lose fragments with molecular weight of about 1,000 (Fig. 1).

The 75,000-MW head fragment is further cleaved by Ps-1 to 25,000 and 50,000 fragments which correspond respectively to the nucleotide[5,6] and actin[7] binding domains identified by tryptic digestion of S-1 (Fig. 2). These head domains from vertebrate striated myosins are then stable even after long incubation periods with Ps-1 (48 h). This selectivity of Ps-1 contrasts with that of trypsin which splits myosin heads into similar domains, but degrades these fragments on longer incubation[16]. Scallop myosin appears, however, to be particularly sensitive to proteolysis, since the head fragments are further digested by Ps-1 (Fig. 1). This property does not appear to be related to the light chain-dependent regulation of this molecule[17]. Vertebrate smooth muscle myosin (turkey gizzard) also exhibits a form of myosin-linked regulation[18], and upon digestion with Ps-1 yields stable head domains of slightly differing molecular weights (47,000 and 28,000) and a 140,000 rod fragment (data not shown).

The sensitivity of the scallop head to digestion permits the new rod fragment to be isolated from this myosin. Most of the degraded scallop head fragments remain soluble at low ionic strength, whereas the scallop Ps-1 rod fragment, with both the regulatory and essential light chains still associated, precipitates in these conditions (Fig. 3*b*). In contrast, all of the heavy and light chain fragments remain associated in Ps-1-digested chicken and rabbit myosin on low ionic strength precipitation or on binding to F-actin.

Electron microscopy of this new scallop rod fragment using rotary shadowing shows predominantly a population of rods terminating in two nubs, each about 100 Å long (Fig. 4*b*). Some variability is found in the appearances of the nub structures, which may reflect the small size and flexibility of this region in myosin[14,19]. Although the head fragments remain associated with the rod in Ps-1-digested vertebrate myosins, shadowed preparations occasionally show molecules with one-nub/one-head and even two nubs (Fig. 4*d*, *e*).

These nubs appear to correspond morphologically to the 'neck' region of the myosin head. Myosin light chains have been localized in this region of both scallop adductor myosin[14] and chicken pectoralis myosin[20]. Moreover, it is likely that the 14,000-MW light chain binding fragment recently isolated from scallop S-1[9] corresponds to a portion of this region. These results, together with the findings presented above, suggest that the neck region of myosin is comprised of the 20,000-MW domain with the associated light chains. We have called this region the 'regulatory domain' because the functional significance of this part of the molecule is established both for scallop[21,22] and vertebrate smooth muscle myosin[18,23,24], and has recently also been suggested for vertebrate striated myosin[25]. In this connection, it is likely that the precise digestion pattern

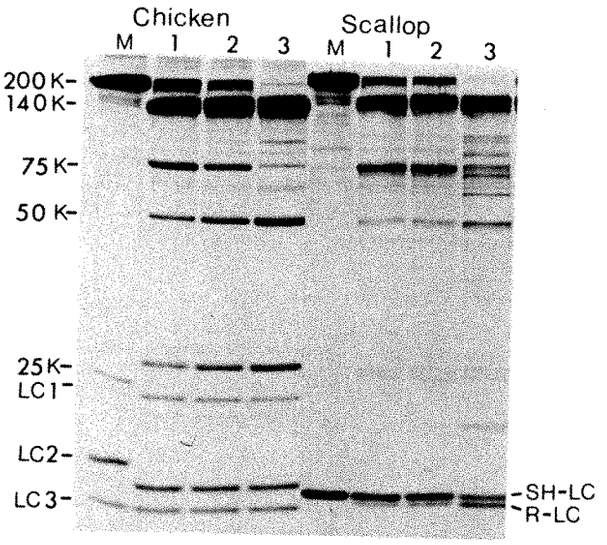

Fig. 1 Myosin fragments obtained by *Pseudomonas* protease (Ps-1) digestion. Digests of chicken pectoralis and scallop adductor myosin were analysed by Laemmli[27] SDS-polyacrylamide gel (12.5%) electrophoresis. M, myosin; lane 1, 1/200 dilution of protease; lane 2, 1/100; lane 3, 1/10. Note the formation of the stable fragments of MW 140,000 for both chicken and scallop myosin. The 75,000-MW fragment is cleaved to 25,000 and 50,000 fragments which are stable fragments from chicken pectoralis myosin; however, these fragments from scallop myosin are further degraded. LC1 and LC2 of the vertebrate myosins and the scallop regulatory light chain (RLC) each lose fragments of about MW 1,000. The rabbit psoas myosin digest pattern was identical to the chicken myosin pattern. Ps-1 is a serine protease with a narrower specificity than trypsin which was isolated from *Pseudomonas aeruginosa*[12]; it has been purified and is being characterized (S.A. and C.C., in preparation). Myosin (5 mg ml^{-1}, 0.5 M NaCl, 0.02 M NaH_2PO_4 *p*H 7.5, 1 mM $MgCl_2$) was digested for 24 h (4 °C) with various dilutions of purified Ps-1 stock (0.3 mg ml^{-1}).

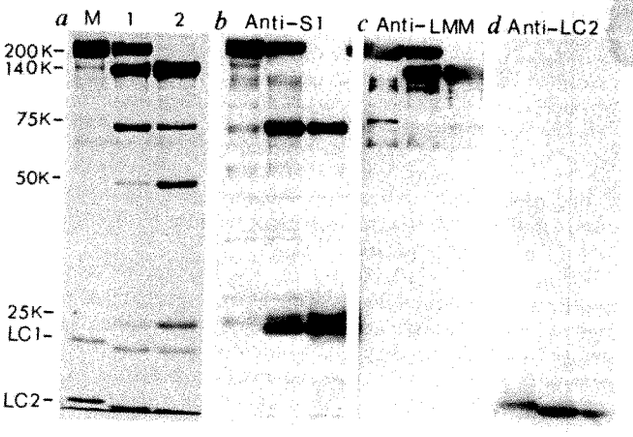

Fig. 2 Immunochemical identification of the fragments obtained by Ps-1 digestion of chicken myosin. *a*, Myosin, M, and the Ps-1 fragments obtained by digestion at two protease concentrations (lane 1, 1/100 dilution; lane 2, 1/10) were electrophoresed on a Laemmli SDS-polyacrylamide gel (11%). This pattern was transferred to nitrocellulose paper and these replicas were probed for specific antibody binding to the myosin fragments using monoclonal antibodies which react with defined regions of the myosin heavy and light chains[20]. *b*, Anti-S-1 (12C5.3) recognizes an epitope in the amino-terminal fragment (MW 25,000) of S-1. This antibody identifies the band (MW 75,000) as an S-1 fragment which breaks down to the amino-terminal 25,000-MW fragment and a 50,000-MW fragment. *c*, Anti-LMM (5C3.2) identifies an epitope that maps to the carboxyl-terminus of the myosin rod. This antibody identifies the 140,000-MW fragment as a larger form (~20,000) of the myosin rod. *d*, Anti-LC2 (7C10.2) identifies the LC2 fragment obtained by Ps-1 digestion. Antibody binding to the nitrocellulose replicas was detected with ^{125}I-labelled rabbit anti-mouse $F(ab')_2$ and autoradiography. The SH–LC and RLC fragment produced by Ps-1 cleavage of scallop myosin have been similarly identified using polyclonal rabbit antisera[28] (data not shown).

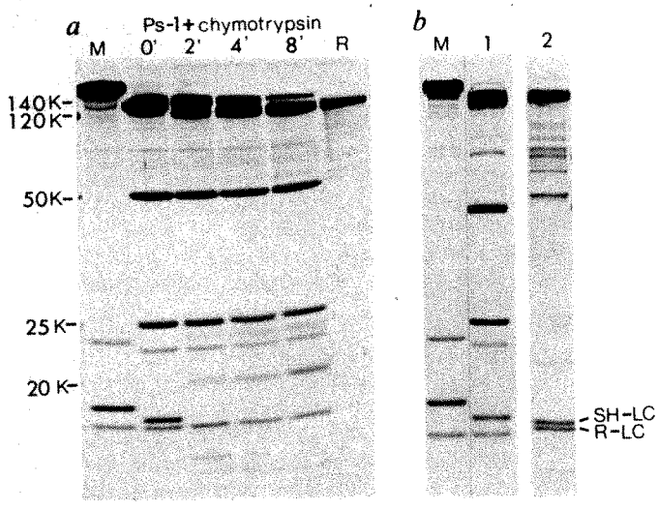

Fig. 3 *a*, The 20,000-MW head fragment can be released from the 140,000-MW Ps-1 fragment by chymotryptic digestion of Ps-1 cleaved myosin. After Ps-1 cleavage, chicken pectoralis myosin filaments (5 mg ml^{-1}, 0.12 M NaCl, 0.02 M NaH_2PO_4 *p*H 7.0, 1 mM EDTA) were treated with α-chymotrypsin (50 μg ml^{-1}) for 0–8 min in conditions that selectively cleave the head–rod junction[3]. The 140,000-MW Ps-1 rod is reduced by chymotryptic digestion to a 120,000-MW fragment which co-migrates with the papain rod fragment (R), and the 20,000-MW S-1 peptide appears simultaneously. This 20,000-MW peptide has been shown to contain the reactive sulphydryl (SH-1) by selective labelling of this cysteine with IAEDANS[16] (data not shown). *b*, SDS-gel electrophoresis of Ps-1-digested chicken and scallop myosin after precipitation by dialysis against low-salt buffer. M, chicken pectoralis myosin; lane 1, Ps-1-digested chicken myosin heavy and light chain fragments remain associated in the washed pellet; lane 2, washed low-salt pellet of scallop digest; bands identified immunochemically as the scallop light chains remain associated with the rod fragment. Variable amounts of the head fragments were present in the rod pellet in different experiments, but in all cases the nub appearance predominated. Digested chicken and scallop myosin were precipitated by dialysis against low salt buffer (40 mM NaCl, 5 mM NaH_2PO_4 *p*H 6.7, 1 mM $MgCl_2$, 1 mM dithiothreitol), and the washed pellets were analysed by Laemmli SDS-polyacrylamide gel (12.5%) electrophoresis.

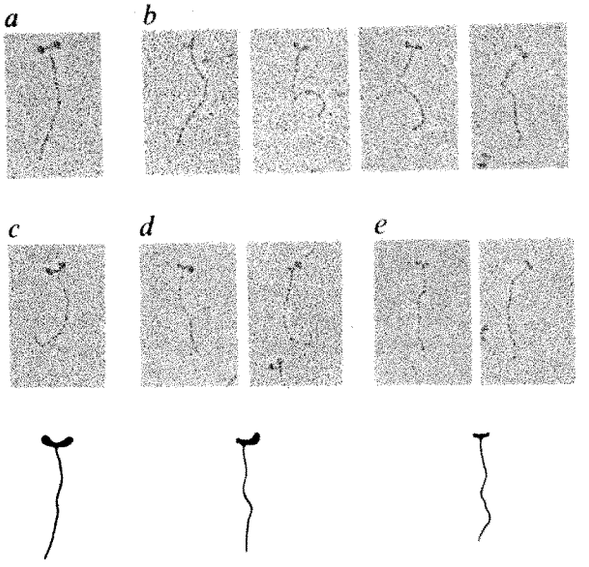

Fig. 4 Electron micrographs of myosin and its Ps-1 rod fragments. *a*, Scallop adductor myosin; *b*, a gallery of scallop Ps-1 rod fragments with associated light chains showing the projecting 100 Å nubs (100 ± 20 Å, $n = 86$); *c*, chicken pectoralis myosin; *d*, chicken Ps-1 rod fragments with one-nub/one-head and *e*, two nubs. The chicken rod fragments were taken from fields of Ps-1-digested myosin in which most of the molecules (>90%) appeared like normal myosin. Tracings of myosin and one-nub/one-head and two-nubbed rod fragments are shown below *c*–*e*. Replicas were prepared by rotary shadowing with platinum[14,20]. Molecules were contrasted with ~12 Å platinum coating in *a* and *b* and ~6 Å platinum coating in *c*–*e*. Magnification ×90,000.

of this region may depend on the physiological state of the myosin molecule (for example, with or without phosphorylation, bound Ca^{2+} and/or nucleotide).

We need a detailed picture of this domain to understand myosin–actin interactions as well as the mechanism of Ca^{2+} control by myosin light chains. The elongated shape of the nub that we have visualized by rotary shadowing is in general agreement with three-dimensional reconstruction results of Vibert and Craig[13] that show a long neck region for myosin heads containing light chains. The precise length and shape of the regulatory domain in the intact molecule are not known, but these results suggest that this domain may span about half the length of the head[14,19]. We have yet to determine the relation between this picture of the head and cross-linking experiments with myosin S-1 and actin[7,8] which suggest that there is a second weak actin-binding site localized in the 20,000-MW domain of the head. A second site has, in fact, been tentatively identified as a 'finger' of low density near an adjacent actin monomer in three-dimensional reconstructions of decorated thin filaments[26]. Studies are in progress to determine whether the nubs can bind to actin.

Visualization of the detailed structure of this region and its relation to the other domains in the head will require X-ray quality crystals of S-1. Selective hinge-cutting enzymes, such as Ps-1, may also prove useful in providing stable intact domains of the myosin head for crystallization. Digestion of native myosin filaments could allow us to examine aspects of the structure of these assemblies which were previously obscured by the size of the myosin heads.

New and Forthcoming Books

Biochemistry of Steroid Hormones

Edited by H.L.J. Makin MA, PhD

Since the first edition of this book was published in 1975, many advances in knowledge of the biochemistry of steroid hormones have been made and a new steroid hormone, vitamin D, has been added to the repertoire. This second edition has been extensively revised and the result is a definitive reference text for all involved in the wide field of steroid hormones.

Second Edition, Early 1984. 640 pages, 314 illustrations. About £45.00

Viral Pathogenesis and Immunology

C.A. Mims MD, FRCPath and **D.O. White** MD, PhD, MSc, FRCPA

This book surveys the pathogenesis and immunology of viral diseases, with the emphasis on those of medical or veterinary importance. The broad yet central coverage of the subject will appeal to senior undergraduates and research workers in the fields of microbiology, cell pathology, immunology and virology.

Spring 1984. 300 pages, 50 illustrations. Paper, about £10.80

Molecular Biology at a Glance: from Cells to Atoms

A.R. Rees MA, DPhil and **M.J.E. Sternberg** MA, MSc, DPhil

Undergraduates in the biological sciences are provided in this text with the essential elements of the molecular aspects of cell biology and biochemistry. The selection of topics range from the description of whole cells and their organelles to the shapes of biological molecules, and several advanced and topical subjects are included, such as the principles and applications of genetic manipulation.

Spring 1984. 96 pages, 35 illustrations, Paper, about £5.00

Behavioural Ecology: an Evolutionary Approach

Edited by J.R. Krebs, *Wolfson College, Oxford* and **N.B. Davies,** *Pembroke College, Cambridge.*

The second edition of this popular text consists of a completely new set of chapters written by some of the most active research workers and teachers in the field of behavioural ecology. The book will serve both as a course text and as an important, up-to-date reference work for research workers in the fields of behavioural ecology, animal behaviour and evolutionary biology.

Second Edition, Spring 1984. 500 pages, 71 illustrations. Cloth, about £18.00, paper, about £10.50

A Synoptic Classification of Living Organisms

Edited by R.S.K. Barnes BSc, MA, PhD

Designed for reference at every level in biological and environmental sciences, this book contains an outline classification of all living organisms from bacteria, through protists, to fungi, plants and animals. The book is intended as a concise pocket dictionary of the diversity of living organisms which will be useful to all biologists.

1984. 276 pages, 67 illustrations. £7.50

Introduction to Modern Mycology Basic Microbiology, Vol 7.

J.W. Deacon BSc, PhD

This book gives a general introduction to the subject aimed at undergraduate students of microbiology, botany and biology, although experienced mycologists will also find it of interest.

'It is clearly written, compact, explanatory account of fungal structure, growth and development, coupled to consideration of the role of fungi in nature ... Dr Deacon's book is currently the best, short undergraduate introduction to fungi on the market.' *Nature* (on the first edition)

Second Edition, Early 1984. 272 pages, 79 illustrations. Paper, about £9.80

Developmental Control in Animals and Plants

Edited by C.F. Graham MA, DPhil and **P.F. Wareing** DSc, FRS

The second edition of this acclaimed text, previously entitled The Developmental Biology of Plants and Animals, includes much new material and extensive revision of the remainder to take account of significant advances in knowledge, especially in the structure of eukaryotic genome and the control of gene expression. This is the ideal textbook for advanced courses in developmental biology.

Second Edition, Early 1984. 520 pages, 257 illustrations. Paper, about £14.80

Human Evolution at a Glance

R. Lewin BSc, PhD

Human Evolution at a Glance is an up-to-the-minute presentation of the fast-moving field of palaeoanthropology, touching on primatology, palaeontology, palaeoecology and geology, taphonomy, molecular biology, archaeology and prehistory. The book gives a concise account of the current status of information and ideas in these pertinent areas and is designed for university introductory courses.

Early 1984. 128 pages, 120 illustrations. Paper, about £5.80

Microbiological Sciences

Recent Trends in Bacteriology, Mycology and Virology

Editor-in-chief: Professor C.M. Brown, *Heriot-Watt, University, Edinburgh*
Editor: Dr. I.W. Dawes, *University of Edinburgh*

Microbiological Sciences is a new monthly periodical for the whole of the microbiological sciences and will be published for the International Union of the Microbiological Societies by Blackwell Scientific Publications. Its contents will include news reports, features and opinions. Most of the articles will be specially commissioned to report and consider all recent developments in such fields as bacteriology, virology and mycology.

Subscription Information

Microbiological Sciences will be published monthly from April 1984, and the subscription rates will be *Institutional:* £75.00 (UK), £90.00 (overseas), US$162.00 (USA and Canada). *Individual:* £25.00 (UK), £30.00 (overseas), US$54.00 (USA and Canada).

CULTURE OF ANIMAL CELLS
A Manual of Basic Technique

by **R.I. Freshney,** *Department of Clinical Oncology, Cancer Research Campaign Laboratories, University of Glasgow*

At last there is a comprehensive self-explanatory guide to the basic techniques of tissue culture. *Culture of Animal Cells: A Manual of Basic Technique* is the first laboratory manual that enables both the novice and experienced researcher to apply the basic techniques of tissue culture.
The manual is a remarkable source of information illustrating and describing, step by step, how to culture cells in vitro, with lucid explanations of the biological principles involved. This readily accessible and extremely informative manual will allow immediate implementation of basic tissue culture techniques for sophisticated research and routine classroom exercises.
It is intended for use by Researchers, Technicians, and Graduate Students in Cell and Organ Physiology; Biochemistry; Microbiology; Genetics; Biomedical Research; Cellular, Developmental, and Molecular Biology; Virology; Pharmacology; Zoology; Anatomy; Histology; Oncology; Pathology; and Neurobiology.

MODERN CELL BIOLOGY, Volume 1
edited by **B.H. Satir**

Modern Cell Biology is a new series providing researchers in cellular and molecular biology with concise articles on the biology of the cell. The intent of the series is to review the current status of research in the field and to provide a base from which future investigations may develop. *Modern Cell Biology* will consistently keep its multidisciplinary audience abreast of the ongoing research on cell biology.
Modern Cell Biology publishes critical reviews of specific areas in cell biology, including personal perspectives and general reviews related to the boundaries of the field or the application of new methods to cell biological problems. From time to time, symposia concerning vital topics in cell biology will appear as special volumes.

Modern Cell Biology Series Volume 1; Series Editor **B.H. Satir**

Contents: Receptor-Mediated Endocytosis; Structure and Function of the Adhesive Glycoprotein Fibronectin; Membrane Biogenesis, Enveloped RNA Viruses and Epithelial Polarity; The Acetylcholine Receptor-Ion Channel Complex: Linkage Between Binding and Response; Index.

June'83 — 216pp
08451 3300 4 — £26.00/$46.80

MODERN CELL BIOLOGY, Volume 2
Spatial Organization of Eukaryotic Cells
edited by **J.R. McIntosh**

Modern Cell Biology, Volume 2: Spatial Organization of Eukaryotic Cells is the proceedings of a symposium honoring retired scientist Keith R. Porter.
It examines current knowledge concerning the mechanisms by which cell structure is established. In addition, this volume reviews structural cell biology in the context of tissue and organ structure by looking at the factors that govern pancellular organization in multicellular organisms.

Modern Cell Biology Series Volume 2; Series Editor **B.H. Satir**

Contents: Organization of Cell Membranes and the Compartmentalization of Cytoplasm; Organisation of the Fibrous Components of Cytoplasm; Cytoskeletal Action in Cytoplasmic Organization; Organization of Nuclear Structure and the Control of Gene Action; Global Organization of Cells and Extracellular Space; Summary; Index.

NERVOUS SYSTEM REGENERATION
edited by **B. Haber, J.R. Perez-Polo, G.A. Hashim** and **A.M.G. Stella**

Nervous System Regeneration discusses new approaches to the problem of elucidating the causes of success or failure in axonal regeneration. The book contains original data as well as reviews of ongoing research and is divided into six main sections. These sections discuss some of the newest techniques available to man and include discussions on the nerve growth factor, neuronotrophic substances, trophic factors, neuronal sprouting, neuronal differentiation and regeneration, and control of motor localization.

Birth Defects: Original Article Series, Volume 19, Number 4,
September'83 — 586pp

DEVELOPING AND REGENERATING VERTEBRATE NERVOUS SYSTEMS
edited by **P.W. Coates, R.R. Markwald,** and **A.D. Kenny**

This book presents integrated approaches to problems that now exist in neurobiology, that can be applied to clarifying a wide variety of neurobiological functions and dysfunctions. It provides an in-depth look at recent viewpoints on a number of frontiers in neural development and regeneration.

Series: Neurology and Neurobiology, Volume 6
January'84 — 284pp
08451 2705 5 — £43.00/$77.40

MEMBRANE BIOPHYSICS II
Physical Methods in the Study of Epithelia
edited by **M.A. Dinno, A.B. Callahan** and **T.C. Rozzell**

This volume reviews new research methods and their use in the study of biological systems, providing insights into epithelial membranes at the microscopic level. The methods presented offer good examples of interactions between scientific disciplines and the state of the art of innovative theoretical and technological advances.

Series: Progress in Clinical and Biological Research, Volume 126
November'83 — 388pp

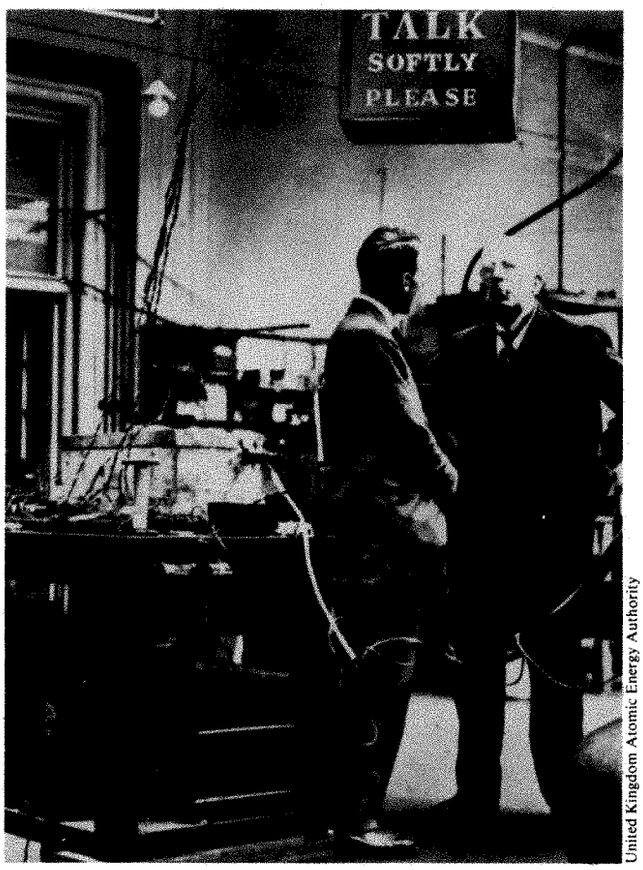
The elephant and the flea

R.V. Jones

Rutherford: Simple Genius. By David Wilson.
Hodder & Stoughton/MIT Press: 1984. Pp.639. £14.95. (*April publication, $25.)*



ERNEST Rutherford's towering stature in the heroic age of twentieth-century physics has made him the subject of many books, memoirs and lectures. And yet, in this new and comprehensive biography David Wilson has illuminated fresh facets of the man and his activities.

First there is Rutherford's work in the First World War for the Royal Navy, which has only been sketchily outlined by earlier biographers. In fact, Rutherford was once described as "lacking in public spirit" because, for example, he went on for a visit to his native New Zealand after the British Association meeting in Australia in 1914, while H.G.N. Moseley and H.T. Tizard rushed by ship across the Pacific, by train across the United States, and then by ship again across the Atlantic, so that they could offer their services in Britain (only, alas, for Moseley to be killed at Gallipoli). But David Wilson has discovered in the papers of the late A.B. Wood much about Rutherford's efforts to assist the Navy on his return — from which it incidentally transpires that credit for the invention of Asdic (or Sonar) should be ascribed to Rutherford as much as to his French colleague, Pierre Langevin. And it was not only by invention that Rutherford contributed: he made many visits to establishments and he joined in trials at sea. In 1917 he was pressing the Navy to bring the scientists much more into the operational picture for "in scientific research it was found to be essential that the researcher should have the widest knowledge and personal experience of the difficulties to be solved" — to which a senior naval officer objected "the only information necessary to be given was that enemy submarines were in the sea, and that means were required to detect their presence".

It was to take the experiences of the Second World War, led by the example of Henry Tizard, to convince the Services of the folly of such a view. And Tizard's second contribution, the famous Tizard Mission to the United States in 1940, was by coincidence anticipated in 1917 by a joint Anglo-French Mission led by Rutherford to acquaint American scientists with developments made in Britain and France.

After the war, his campaign for scientific support for the Navy led to the foundation of the Admiralty Research Laboratory.

When, in 1919, Rutherford became Cavendish Professor at the University of Cambridge, his qualities as a scientific administrator were frequently called upon by the British Government, and David Wilson believes that he has made the first study of Rutherford in this capacity. His activities ranged from dealing with individual problems, such as the future of the Artillery College at Woolwich, to being President of the Royal Society and Chairman of the Scientific Advisory Council of the Department of Scientific and Industrial Research, in both of which offices he stimulated much action and prompted many forecasts of national needs; and in 1933 he headed the Academic Assistance Council with the objective of aiding academic refugees from the Nazis.

United Kingdom Atomic Energy Authority

Rutherford (right) at the Cavendish — "spreading tobacco ash and noise, [ruling] the laboratory as a tribal leader".

Wilson has drawn on many sources to depict Rutherford's temperament and character. "Brash and noisy all his life", or more accurately, quoting Henry Tizard:

> He had a boisterous sense of fun and a loud laugh. By precept and by example he helped keep our minds free from cant. He hated pomposity and artificiality. He loved simple people and simple ways, and lived a simple life. . . . lived a life of feverish intellectual activity relieved by short periods of magnificent idleness. When he took a holiday it really was a holiday.

Wilson's carefully detailed account of Rutherford's interactions with the many physicists who worked with and around him provides an illuminated cavalcade through forty of the most exciting years in physics: with Soddy, Moseley, Geiger, Marsden, C.G. Darwin, the Braggs, Langevin, C.R.T. Wilson, von Hevesy, Bohr, Chadwick, Blackett, Cockcroft and Kapitza among its members. A whole chapter, in fact, is sympathetically devoted to Kapitza who, Wilson says, came closest to being the son whom Rutherford never had. "The Crocodile" was the nickname given by Kapitza to Rutherford; and this is why, when the Mond Laboratory was built (in Cambridge), Kapitza asked Eric Gill to carve a crocodile over its main door. Unfortunately, the Laboratory had scarcely been opened when Kapitza was irrevocably detained while on a visit to Russia, despite the efforts of Rutherford and many others to persuade the Soviet authorities to release him.

One item which Wilson records has, incidentally, corrected a long standing misjudgment of my own concerning F.A. Lindemann (later Lord Cherwell). When I was in his laboratory in the 1930s I felt that it was unfortunate for physics in Britain that he had not come to an understanding with Rutherford about the division of interests between the Clarendon in Oxford and the Cavendish, instead of the competition exemplified by the 1932 race to liquefy helium and so steal the Mond Laboratory's thunder before it opened. Thanks to Wilson's delving, I now learn that on his election to the Clarendon in 1919 Lindemann wrote to Rutherford in the following terms: "I am anxious to work in collaboration with Cambridge and the other schools of physics, both to prevent overlapping . . .". Unhappily, relations turned out otherwise.

As background to Rutherford's life and work we are given excellent descriptions of the opening up of New Zealand and of the development of science in Cambridge in the nineteenth century, and in particular of the establishment and achievements of the Cavendish Laboratory in the first seventy years of its existence, occasionally spiced with such episodes as the refusal of the

seventh Duke of Devonshire to allow his sons to have a scientific education despite his own accomplishments of Second Wrangler and Smith's Prizeman, and his generous foundation of the Cavendish. Wilson has of course had a great deal of material to draw upon from previous biographies and memoirs, but he has gone through these with a critic's eye and resolved discrepancies between them, and has dug further into the background.

As a result we have a biography which not only exposes Rutherford's contributions in fields which have hardly been treated before, such as his work for the Navy, but also a careful, almost blow-by-blow, account of his researches in Cambridge, Montreal, Manchester and then back again in Cambridge, starting with his magnetic detector for radio waves and his work with J.J. Thomson, leading on to the discoveries which proved him to be the greatest experimental physicist of this century: radon, the alpha-particle, the nuclear atom and nuclear disintegration. Radon, or "emanation", was discovered by the curious observation that the electrical leakage in an air-filled box containing thorium oxide was greater when the door was closed. Both the observation and the remorseless pursuit of its explanation were typical Rutherford.

Just how difficult the pursuit of explanation could be was exemplified by the time it took him to formulate the concept of the nuclear atom after the crucial observation had been made by Geiger and Marsden, in the spring of 1909, that while nearly all alpha-particles passed through a thin foil as though it were completely transparent, a few were deflected through large angles. "Every schoolboy" ever since has known the explanation: but at the time all the physicists concerned, Rutherford included, were baffled. "It was as though", he said, "you had fired a fifteen-inch shell at a piece of tissue paper and it had bounced back at you." More than eighteen months were to pass before Rutherford could give the news in a letter of December 1910 to a colleague: "I think I can devise an atom much superior to J.J.'s for the explanation of and stoppage of alpha- and beta-particles. . . . It will account for the reflected alpha-particles observed by Geiger. . . .".

David Wilson, a science journalist, is modest about his own command of physics, but I found only one small point where his account might have been helpfully expanded. It concerns Hertz's failure in 1883 to deflect cathode rays electrostatically: when such a superb observer and experimenter failed to find any deflection, the discovery of the electron was probably held up by several years, for it seemed that cathode rays were uncharged. Wilson says that J.J. Thomson suspected that the negative result was due to pressure of gas in the discharge tube, and so repeated the experiment (with the better vacuum obtainable in 1897) when deflection was immediately observed. It was not the residual pressure of gas in the discharge tube which had directly produced the negative result, but the fact that the gas became ionized, and the ions had been attracted to the deflecting plates until they built up a space-charge which neutralized the original deflecting field. The incident is worth remarking for its lesson in showing how one of the greatest of all experimental physicists, with radio waves and the photoelectric effect to his credit, could for once be let down by imperfection of technique.

If I miss anything in this magnificent biography, it is the multitude of anecdotes and apothegms which Rutherford's name immediately recalls. I myself remember, for example, how at a lecture in Oxford in the 1930s, Rutherford squashed E.A. Milne when the latter asked him how he knew that the heavy particles were in the nucleus at the centre of the atom, and not the electrons with the heavy particles orbiting the periphery as in a centrifuge. "Well", boomed Rutherford, who was a big man, over Milne, who was a small one, "when you have an elephant and a flea you assume it is the flea that jumps!".

Those with a taste for more anecdotes can doubtless dig for them in the seventeen pages of notes and five pages of bibliography with which David Wilson concludes his account. It is simply one of the best. □

One objective for physicists

Alan H. Guth

Unity of Forces in the Universe.
By A. Zee.
World Scientific (distributed by Wi 1983. Two volumes, pp. 1,076. E volume hbk £40, $57; pbk £16.5(

To a particle physicist, the 1960s no like the Dark Ages. Of the four physical interactions, electromag was the only one for which a successful theory existed. Howev last years of the decade marked the ning of a period of enormous activi since the 1920s had physicists mad rapid and exciting progress in standing the fundamental laws of The work of Weinberg, Salam, G and 't Hooft was synthesized perfectly acceptable theory of the we electromagnetic interactions. Mea the theory of quantum chromody emerged, and it gradually came to garded as the correct theory of the interactions. Thus, by the early three of the four interactions were stood, with only gravity (at the qu level) remaining a deep mystery.

With morale bolstered by triumphs, particle theorists then be attempt to unravel the physics of scales far beyond those that can be r in available or even fores accelerators. The watchword of th movement in particle theory is *unit* as physicists of the nineteenth centu covered that electricity and magnet inextricably linked, their twentieth-c heirs are now trying to show that interactions in nature are simply manifestations of a single unifying

The movement towards unity in has given rise to a vast number of pu papers. For example, there are no 1,300 which cite the original work Georgi and S. Glashow on the SU(5 unified theory. In preparing hi volume collection, A. Zee has ca chosen 78 papers to illustrate the im developments in the quest for uni papers cover many aspects of the theme, and thereby reflect admira exciting developments in particle over the past decade. In addition, provided about 100 pages of summary and explanation to ser companion and guide to the re papers. The reader is assumed familiar with the basics of quantu theory, including non-Abelian theories. For prospective readers w this background, the author has inc short list of suggested sources.

The two-volume set is divided chapters, each of which contains pages of explanatory text and

reprinted articles. The explanations are concise yet clear, summarizing the important developments and unsolved problems in a given area. Although the information is densely packed, the style maintains a flavour of informality. With liberal use of quotation marks, Zee writes about the "see-saw mechanism" of generating neutrino masses, and of the "lopsided" versus the "orthodox" pattern of symmetry breaking in the SO(10) grand unified theory. He also informs us, in a footnote attributed to Howard Georgi, that the SO(10) theory was actually discovered half an hour before the SU(5) theory. I am still trying to imagine how breathtaking a day that must have been.

Volume I is concerned mainly with the basics of grand unification, founded on the groups SU(5), SO(10) and E(6). This volume also includes a two-part "Instant Review of Group Theory", as well as chapters on proton decay, and on attempts to understand the existence of three families of fermions and to determine the fermion masses. Volume II begins with five chapters on cosmology, emphasizing the impact of recent developments in particle physics. Writing primarily for particle physicists, Zee begins with a short course on basic cosmology. The explanatory notes will be particularly useful to the beginner, and the reprints include many of the classic papers of George Gamow and his collaborators. Subsequent chapters deal with the generation of the matter–antimatter imbalance, the theory of galaxy formation (with or without massive neutrinos) and the inflationary universe model. The remainder of Volume II includes accounts of dynamical symmetry breaking and composite models, as well as a brief discussion of the attempts to include gravity in the programme of unification.

A quality of the books which I particularly admire is the author's frank and unassuming tone. Zee points out that "the selection [of papers] assuredly reflects the author's idiosyncracies and the fact that while he has certainly not read every paper in the field, he has definitely read his own papers". (In fact, the books contain only six of Zee's articles, all of which seem quite appropriate to me.) In an effort to encourage the student who might be frightened by the vast volume of literature in this field, Zee points out that "it is not even necessary to read all the papers reprinted in this volume. This writer certainly hasn't". Nor, I confess, have I. □

Alan H. Guth is an Associate Professor of Physics at the Massachusetts Institute of Technology.

Basic methods

Roger Patient

Techniques in Molecular Biology.
Edited by John M. Walker and Wim Gaastra.
Croom Helm/Macmillan, New York: 1983. Pp.333. Hbk £19.95, $29.95; pbk £9.95.

THE success of a textbook, like that of a lecture, is dependent upon a clear idea of the likely audience: the authors and editors of *Techniques in Molecular Biology* appear to have largely satisfied this important criterion. The main readers will be final-year undergraduates (especially project students) and postgraduates embarking on research. Established research workers will find most of the book familiar, but will value its presence in the laboratory when employing a new technique or when suffering one of those irritating failures of a technique which has been working for years. In addition useful tables and titbits of information are sprinkled throughout.

The scope of the book is fairly comprehensive, covering the separation and *in vitro* synthesis of proteins and nucleic acids, their transfer to solid supports and detection, determination of their amino acid or nucleotide sequences, and molecular cloning. Very little is considered too basic for inclusion: nick translation, for instance, gets a whole chapter. The information is well-organized and concisely presented, with a lot of internal cross-references. In relation to other literature available, this publication intercalates quite nicely between *Molecular Cloning: A Laboratory Manual* (Cold Spring Harbor Laboratory, 1982), which contains an enormous amount of practical detail, and the *Genetic Engineering* series, published by Academic Press, which contains none.

Criticisms of the book centre on a very inconvenient way of listing references and a number of omissions or incomplete treatments of particular techniques. For instance, there is no good description of the direct application of nucleic acids to nitrocellulose and subsequent hybridization (the so-called "dot-blot" technique), and only cursory treatment of *in situ* immunoassay techniques for screening bacterial recombinants. Occasionally, the information provided is actually misleading, as in the statement that ribonuclease-free deoxyribonuclease is available commercially (in practice, further purification is usually necessary before use). Finally, the problems associated with particular techniques are sometimes glossed over, as in the cases of M13 nucleotide sequencing, which has taken a number of laboratories a long time to establish, and assays of *m*RNA solutions using ^{3}H polyuridylic acid, where problems with variability of polyadenylic acid tail length and reproducibility are often experienced. □

Roger Patient is a Lecturer in the Department of Biophysics at King's College, University of London.

Bangosomes: the past and the present

J.A. Lucy

Liposome Letters.
Edited by A.D. Bangham.
Academic: 1983. Pp.421. £17.50, $29.
Liposomes.
Edited by Marc J. Ostro.
Marcel Dekker: 1983. Pp.400. SwFr.157, $58.75.

Liposome Letters is a most unusual if not unique book, but that will not surprise those who are personally acquainted with the editor. In 1982 Alec Bangham wrote to some fifty scientists who have been concerned in one way or another with liposomes to suggest they send him informal letters, poems etc., that chronicle an anecdote, observation, hypothesis or comment about liposomes. His intention was that their offerings should recapitulate the developments and diversification of the liposome "membrane" model from its early days up to the present. In the preface he says that this formulation derived from a feeling that too much of our scientific writing is stereotyped, banal, platitudinous and devoid of all sensibility to the fabric of life in scientific research, success or failure. After just twenty years, I now realize why Alec considered my initial draft of a joint paper with him to be "pretty turgid stuff".

It is surprising what one can find in this volume. For example I see that in the preface by Papahadjopoulos, I and three other named villains are pilloried for apparently considering that he and Bangham were simply wasting their time in the early stages of work on liposomes. Then, Racker's chapter is punctuated by five Lessons, the last of which reads:

> After you publish rejoice when other scientists don't believe what you know to be true. It will give you extra time to work on the phenomenon in peace. Whey they start claiming that they have discovered it before you, look for a new project.

His chapter ends with full-page photocopies of two letters, one from Racker to Bangham that reads "The answer to your question in your letter of March 1, 1982, is yes", and the other from Bangham to Racker replies "Thanks". Scherphof has contributed a witty three-page dissertation on how to pronounce the word liposome that includes a "Light-macrograph of the essential part of a Dutch technician caught in the act of preparing [blowing] an animal-size hemilamellar liposome (ASH-L). Bar is 1,0cm". The text says "For anybody watching this picture there cannot remain a shadow of doubt that a liposome is a LIP′əsōm′, can there? From Groningen, with LUV, P.S. You should see her in full colour!".

Most papers are, however, primarily serious but with lighter touches, such as the Molecular Trojan Horse that illustrates the article by Dimitriadis on the transformation of eukaryotic cells, and perhaps most of the contributions would not seem particularly out of place in a more conventional book. (Each contribution has been photographically reproduced from the original typescript, but none is difficult to read.) There are some 40 articles in all, from which much can be learned about liposome lore. Anyone who has been personally involved with liposomes, or who knows workers in the field, will also be interested by the anecdotes. Those who have not might find them slightly tedious. The unusual format has, however, encouraged authors to be more forthright than usual, and this is a valuable feature in itself. For example, to quote finally from George Poste:

> I was highly skeptical (and remain so) about the feasibility of targeting liposomes to tumor cells in solid neoplasms and their metastases *in vivo*. . . . My criticisms are directed only to those proponents of targeting who chose to ignore the substantial problems created by anatomic and physiologic factors *in vivo*. . . . Overselling always carries the danger that real opportunities may be lost because of skepticism elicited by earlier extravagant claims which have failed to come to fruition.

Although *Liposomes* edited by Ostro is of comparable size to *Lipsome Letters*, and was published at about the same time, it appears to have taken longer to produce perhaps because it is not based on camera-ready copy. There are eight contributions, five of which are from the pens of authors who also appear in Bangham's volume. In Ostro's book, however, their contributions are basically more serious (influenced by Bangham, I nearly wrote more prosaic), or rather all of them except Bangham's own short historically-orientated chapter. The editor has attempted to assemble reviews of various areas of liposome research in such a way that the volume represents a compilation of the major work in the field since 1965 (up to, as far as I can see, fairly early in 1982).

In the preface Ostro (whose own affiliation is The Liposome Company) comments that 30% of those attending a recent meeting on liposomes were affiliated to commercial laboratories. This is a useful laboratory reference book and it similarly reflects current interest in the practical and commercial applications of the targeting of liposomes as delivery systems. Thus the three chapters (liposomes as a tool in molecular biology; immunologic aspects of liposomes; therapeutic applications of liposomes), which are most concerned with various aspects of this topic, occupy considerably more than half of the volume. □

J.A. Lucy is Professor of Biochemistry at the Royal Free Hospital School of Medicine, London.

Catastrophe, chaos and delay

Athel Cornish-Bowden

Mathematical Models in Molecular and Cellular Biology.
Edited by Lee A. Segel.
Cambridge University Press: 1983. Pp.768. Pbk £15, $29.95.

WHY is the story of the mathematician who opened a lecture with the words "Consider a spherical elephant" not funny? Biologists need to understand this before they can appreciate the value of mathematics and overcome their suspicion of it. Some caution is justified, as there are many who seem to regard numbers and equations as a convenient shield for the poverty of their ideas, but mathematics has made considerable contributions to biology and deserves to be taken seriously.

To give one example: a valid theory of metabolic control cannot be developed without a mathematical framework that extends beyond the elementary kinetics of isolated enzymes; in consequence, biochemists who reject a mathematical approach continue to be misled by oversimplified ideas, such as "bottleneck enzymes", "controlling steps" and so on. In some areas of biology it is easy to check by experiment whether a mathematical theory makes correct predictions, even if one does not understand the mathematics. Metabolic control, however, is difficult to study by experiment (other than by computer simulation), and so one cannot easily convince the sceptic that metabolic fluxes must be largely unaffected by moderate changes in the concentration of almost any enzyme. In such cases scientists who deny themselves all but the most elementary mathematics are also denying themselves understanding.

Anyone genuinely interested in learning how mathematics is being applied to research problems in biology can hardly do better than begin with *Mathematical Models in Molecular and Cellular Biology*, a book first published in 1980 and now available in paperback. Dr Segel has taken his responsibilities as editor seriously and has produced a real book, not just a haphazard collection of papers. Indeed, the individual authors are given so little prominence that their names do not appear at the beginnings of their chapters.

I particularly liked the obvious efforts taken to support the mathematics with a readable text and to make it believable. For example, the information that the equation $x_{t+1} = rx_t(1-x_t)$ can generate chaotic (aperiodic) behaviour is accompanied by the instructive suggestion that "the reader simulate the difference equation on a hand calculator to see this". After doing just that, I found it much easier to accept the important biological message that "phenomena that look chaotic may come from simple underlying laws". As the author of that chapter remarks, "the implications . . . are most unsettling"!

I was disappointed to see that population genetics is mentioned only in passing, but this was the only major omission that I noted. Some other topics, such as elementary thermodynamics and enzyme kinetics, are also dealt with briefly or not at all, but there would be little point in filling a book of this kind with the staples of general biochemistry texts.

Catastrophe, chaos, delay. . . . It will be evident by now that the title of this review is not a comment on the book: it is inspired by the editor's list of some of the mathematical concepts to be discussed in a biological context, but there is much else to interest anyone with a lively mind. □

Athel Cornish-Bowden is a Lecturer in the Department of Biochemistry at the University of Birmingham, UK, and the author of Basic Mathematics for Biochemists *(Chapman & Hall, 1981).*

Sex in society

Stuart Sutherland

Men and Women: How Different Are They?
By John Nicholson.
Oxford University Press: 1984. Pp.193. Hbk £9.95, $19.95; pbk £2.50.

ONE OF the more curious aspects of social research is that it so rarely produces definitive results. This is especially true in the area of sexual differences and their origins: *Men and Women* is a rather cursory survery of the evidence on this topic. It is intended as a popular book and rarely cites primary sources or gives enough details of experiments and surveys to allow the reader to judge for himself — or, one should perhaps add in this context, herself. John Nicholson appears to be bent on showing first that sex differences are either non-existent or small, and second that where they exist they are caused by socialization not by genetic effects. His arguments are often cunning, but that does not prevent many of them from being fallacious. Here are some examples.

In attempting to disprove the existence of an innate maternal drive, he uses as a counter-argument baby-battering by mothers. This is like arguing that hunger is not largely innate because some people are anorexic. Again, he argues that even in animals the maternal drive is a weak one, because it often disappears if the mother is separated from her offspring for a short time. But the development and maintenance of many innate drives are known to depend on the presence of the appropriate stimulus. Given the importance of maternal behaviour for the survival of the species it would be remarkable if no geneti

Elm

R.H. RICHENS

'This is an extensive and penetrating account of the whole biology of the elm and of the tree's place in the folklore and art of Britain . . . the marriage of art and science, united in praise of elm . . . is remarkably successful.'
New Scientist

0521249163 **£35.00 net/ $69.50**

Plants and Microclimate

A Quantitative Approach to Environmental Plant Physiology

HAMLYN G. JONES

Designed to provide a soundly-based introduction to the effect of microclimate on plant physiology, this book examines those features of the atmospheric environment that particularly affect plants, and provides a lucid overview of the physical and physiological principles involved.

0521248493 **Hard covers £27.50 net/ $54.50**
0521270162 **Paperback £12.50 net/ $21.95**

Plant Biotechnology

Edited by **S.H. MANTELL** and **H. SMITH**

This straightforward introduction to plant biotechnology examines the subject's main areas of activity and assesses the future potential of each.

Society for Experimental Biology Seminar Series 18

0521245508 **£35.00 net/ $69.50**

Yeasts: Characteristics and Identification

J.A. BARNETT, R.W. PAYNE and **D. YARROW**
with 500 photomicrographs by **LINDA BARNETT**

The most complete and up-to-date survey of its kind ever published, this volume describes the mode of reproduction and principal characteristics of some 470 species of yeast.

0521252962 **£75.00 net/ $150.00**

The Biochemistry of Natural Pigments

G. BRITTON

This textbook describes the structures and properties of the main groups of natural pigments, their distribution in nature, their biosynthesis and functions and their associated biology and chemistry.

0521243922 **£30.00 net/ $59.50**

The Lively Membranes

SIR RUTHERFORD ROBERTSON

This book summarises the principles of structure and functions of membranes at the molecular level and uses examples drawn from the entire range of living organisms.

0521237475 **Hard covers £12.50 net/ $29.95**
0521282020 **Paperback £4.95 net/ $11.50**

The Physiology of Trematodes

Second Edition

J.D. SMYTH and **D.W. HALTON**

An entirely re-written edition which takes account of recent advances in our understanding of ultrastructure, cytochemistry, biochemistry and immunology.

0521222834 **Hard covers £30.00 net/ $59.50**
0521294347 **Paperback £11.95 net $23.95**

Comparative Vertebrate Endocrinology

Second Edition

P.J. BENTLEY

'Bentley . . . has reflected the many advances made in endocrinology in the six years since the first edition was published. Retaining the same framework and approach, each section has been updated, many new figures added . . .'
Trends in Biochemical Sciences

Current Microbiology

An International Journal

Section Editors: **A. Balows,** Atlanta (medical microbiology); **P. Baumann,** Davis (general microbiology, physiology)

Featuring concise yet thorough reports written by leading researchers from all over the world, this international journal presents the most up-to-date information available in the entire field of microbiology. Each issue contains up to 20 short papers which discuss medical, non-medical, pure, applied, taxonomic, historical, theoretical, practical, methodological, and conceptual advances now being made. (ISSN 0343-8651, Title No. 284).

Archives of Microbiology

Editors-in-Chief: **G. Drews,** Freiburg; **J. L. Ingraham,** Davis; **H.-G. Schlegel,** Göttingen

Known as a forum for announcing discoveries of new bacteria, the **Archives of Microbiology** publishes results of basic research on bacteria and other mircoorganisms, including fundamental aspects of ecophysiology, physiological genetics, and biotechnology. Results of special interest can be rapidly published as short communications.
(ISSN 0302-8933, Title No. 203)

Applied Microbiology and Biotechnology

(formerly European Journal of Applied Microbiology and Biotechnology)

Editor-in-Chief: **H. J. Rehm,** Münster

Applied Microbiology and Biotechnology is an international journal presenting research articles on topics including:

- biotechnology (applied genetics and gene technology in relation to biotechnology)
- industrial microbiology (e. g., fermentation)
- environmental microbiology (such as sewage purification)
- applied microbiology (particularly food microbiology)

(ISSN 0171-1741 Title No. 253)

European Biophysics Journal

(formerly Biophysics of Structure and Mechanism)

Managing Editor: **P. Bayley,** London

The **European Biophysics Journal** presents the latest research findings in a wide range of areas employing the principles of physical science to understand biological structure and function. Topics include molecular structure and interactions, membrane and receptor biophysics, thermodynamics and energetics of biological processes, and theoretical biophysics.
(ISSN 0340-1057 Title No. 249)

Collection of Methods for the Microbiological Examination of Foods

Edited by W. Schmidt-Lorenz

There is a greater need for the microbiological examination of foods because of the recent, almost world-wide, increased emphasis on the hygiene, safety and quality of foods. Microbiological standards or specifications for foods can only be established when methods which give reproducible results are readily available. Difficulties are sometimes encountered by laboratory personnel because official and unofficial methods appear in many different publications. To help solve this problem, members of several scientific societies have compiled a comprehensive collection of methods for testing the various groups of products. This collection of methods will be useful – amongst others – to food processors throughout the world if they wish to ship their products to Germany because they must examine their products by the methods described here.

The collection is to a large extent bilingual (German and English). In particular the 15 page introductory text is presented in its entirety in both English and German.

The collection comes complete with two loose-leaf binders. In addition, the publication of „special issues" which each deal with only one product-group is being prepared. If you wish to receive further information please write to the address given below.

I wish to receive further information about „Schmidt-Lorenz, Collection of Methods for the Microbiological Examination of Foods".

provision had been made for the appropriate behaviour along with the appropriate physical apparatus for nurturance.

Nicholson's treatment of differences in aggression is equally odd. Having quoted a mass of evidence that suggests that men are more aggressive than women, he writes "In the absence of evidence to the contrary, I suggest we assume that men *are* more aggressive than women". Elsewhere he tries to dispose of the argument that the greater tendency of males to be aggressive is — at least in part — caused by the presence of higher levels of testosterone. He cites the case of girls who were exposed as fetuses to exceptionally high levels of androgens and notes that their behaviour tends to be tomboyish, but he fails to draw the obvious conclusion.

Despite his bias against biological explanations, Nicholson writes clearly though without much wit or charisma. Some of the results he provides may titivate. Half of American fathers have never changed a nappy — not even a disposable one; the difference in the athletic records of men and women has been enormously reduced over the past 50 years (one hopes this has nothing to do with steroids); women's scores on examinations are not influenced by the point in the menstrual cycle at which they take them; men and women do not differ in self-esteem, ambition or ability, but men are the more confident sex.

Since Nicholson virtually rules out innate factors as responsible for the differences between men and women, he is not unnaturally puzzled that all known societies are patriarchal: men occupy the prestigious jobs, and in encounters between members of the opposite sex, both men and women almost invariably feel that the man is dominant. One of his proposed solutions is that men's aggression and desire to dominate stems from their shame that they cannot have babies, a proposal that could surely be disposed of fairly quickly by a social survey — unless of course the hurt goes so deep that men are ashamed to admit it. There is another possibility that he does not consider. Perhaps men and women are innately disposed to act in different ways to members of the opposite sex. This would account for much of the evidence he quotes, for example, the fact that both men and women treat boy and girl babies differently even when the have been misled about the sex of the baby. The initial bias would determine the process of socialization, which would in turn increase the bias. The explanation would also account for one of Nicholson's recurrent themes: despite the feminist movement, it is hard to demonstrate any significant changes over the past 20 years in attitudes or practices relating to the interaction of the sexes. □

Histochemistry and cytology

Robert Olby

History of Staining, 3rd Edn.
By George Clark and Frederick H. Kasten.
Williams & Wilkins: 1983. Pp.304. $29.95, £22.25.

A SERIES of articles published in the journal *Stain Technology* between 1928 and 1933 formed the text of the first edition of this book, which was compiled by H. J. Conn and appeared in 1933. With the additions to the second (1948) and present (third) editions, the book is now virtually twice its original size. Successive editions have followed Conn's intention, which was to cover the field broadly rather than going deeply into specialized topics. As is typical of collections of reprinted papers, there was in the original book a lack of any overall thesis which might have acted as an organizing principle; unhappily, this feature has been perpetuated rather than overcome in the later editions.

The subject matter in this new edition has been organized in terms of, first, the different sorts of dyes, second, the several kinds of biological materials — bacteria, blood, connective tissue, nerve tissue, antibody and antigen — and, finally, selected major figures such as Sir John Hill, Joseph von Gerlach, Rudolf Heidenhain, Paul Mayer, Paul Unna, Paul Ehrlich, Walther Flemming, John Belling, Gustav Mann, Frank Mallory and Ralph Lillie. It is not clear why Rudolf Heidenhain was chosen rather than his son Martin, author of the iron-haematoxylin staining procedure and pioneer in the use of aniline dyes, but the other figures are reasonable choices.

The early history of biological staining centres on the use of carmine from the cochineal insect and haematoxylin from extract of logwood. Next came the aniline dyes, following upon Perkin's production of "mauve" in 1856 — safranin, methyl violet, aniline blue, eosin, methyl green, methylene blue, acid fuchsin and so on. The golden era of cytology in the 1880s and 1890s, in which the details of the chromosomes, and the nature of cell division and fertilization were revealed, rested upon the growing range of stains and techniques described in the book.

The history of the relationship between histochemistry and cytology is a fascinating one which goes back to the very early days. In his chapter on protein and nucleic acid histochemistry, Professor Kasten takes us back to François-Vincent Raspail's use of the starch–iodine reaction in 1825. He stresses the importance of Miescher's and Zacharius's study of the relation between nuclear staining and the chemistry of the nucleus. But it was Feulgen's "nucleal reaction" which Kasten sees as the decisive influence in establishing the localization of proteins and nucleic acids in the cell, paralleling the distinctive staining reactions of nucleus and cytoplasm, and overturning the old belief in the restriction of DNA to animal tissues and RNA to those of plants.

There are obvious difficulties in writing about a collection of techniques and leading technicians for anyone but specialists. No doubt this text will be much appreciated by them. The general reader, however, will surely require a very different sort of book, one organized not around specific stains and famous figures but concentrating on general issues, such as the much-debated question of the existence of organized structures in the cell, their persistence and their replication. Intimately connected with this issue were fundamental questions over the nature of fixing and staining themselves. Did the process of fixing create structures which then adsorbed the stains to produce a spurious architecture within the cell? Was staining simply physical adsorption as Albert Fischer maintained? Were the cytoplasmic organelles discovered in the nineteenth century mere artefacts as W. B. Hardy held? This debate is mentioned on p.199 but not developed. From the book, one would not have guessed that the tenets of cytology were seriously undermined by these fundamental criticisms, and that the emerging tradition of experimental cytology, its practitioners having become sceptical of the claims of classical cytology, concentrated upon the biophysical properties of protoplasm and the presence of surface phenomena in the cytoplasm.

Needham and Peters in the 1930s envisaged a "cytoskeleton" in the cytoplasm which was a colloidal formation and not an organelle in the sense of classical cytology. This rejection of the tradition of classical cytology was not reversed until the techniques of freeze-drying, electron microscopy and ultracentrifugation had been introduced in the 1930s and successfully developed in the 1940s. Kasten points out how important was Feulgen's "nucleal reaction" in this change of opinion. It should also be stressed that histochemists were in the van of the movement beginning in 1950 to establish nucleic acids rather than proteins as the hereditary material. This decision arose from the results of the quantitative study by histochemists of the content of DNA and protein in the chromosome cycle of dividing cells and from the discovery of the halving of DNA content during reduction division. That the contribution of the histochemists is often ignored suggests that this tradition has yet to receive a just evaluation from historians. The present book offers an introduction and valuable bibliography for any such attempt. □

Robert Olby is Reader in the History of Science at the University of Leeds.

Scottish geology for the 1980s

W.S. McKerrow

Geology of Scotland, 2nd Edn.
Edited by G.Y. Craig.
Scottish Academic Press/Halsted: 1983. Pp.472. Hbk £35, $54.95; pbk £17.50.

Scotland's Environment During the Last 30,000 Years.
By Robert J. Price.
Scottish Academic Press/Columbia University Press: 1983. Pp.224. Hbk £27.50, $41.50; pbk £15.

GEOLOGICALLY, Scotland is a small but significant part of the world. Its standing is due to a combination of factors: diverse geology, good exposures and attractive landscape for the field geologist, and especially its wealth of geological literature. James Nicol was very wrong when he stated (in his 1844 *Guide to the Geology of Scotland*) that "...in a country which has been so frequently investigated by eminent geologists, it is evident that little absolutely new can be expected". The reverse is true: the better documented the geology, the easier it is to make further advances. Scottish studies in deformation, metamorphism, igneous petrogenesis and Palaeozoic stratigraphy have all led the world at different times during the past two centuries. The names of Hutton, Judd, Geikie, Lapworth, Peach and Horne, Barrow, Harker, Bailey, Richey, Read and Kennedy help to remind us of some of the advances which came from Scotland. What is Scotland doing for geology today?

Since 1965, when Craig produced the first edition of *Geology of Scotland*, our understanding of geological processes has progressed greatly. We now know more about the rates of crustal processes, structural lineaments, the deep crust, palaeolatitudes, heat flow and the continental shelf around Scotland. We also have plate tectonic models to assist us in finding analogues (from other times and other continents) to some of the major tectonic events in the geological history of the area. Most of these advances are recorded in the new edition, but the different contributors each have their own personal approach to the new facts and the new ideas. We now have much clearer views on the significance of many rocks and structures which previously were baffling or just interpreted wrongly.

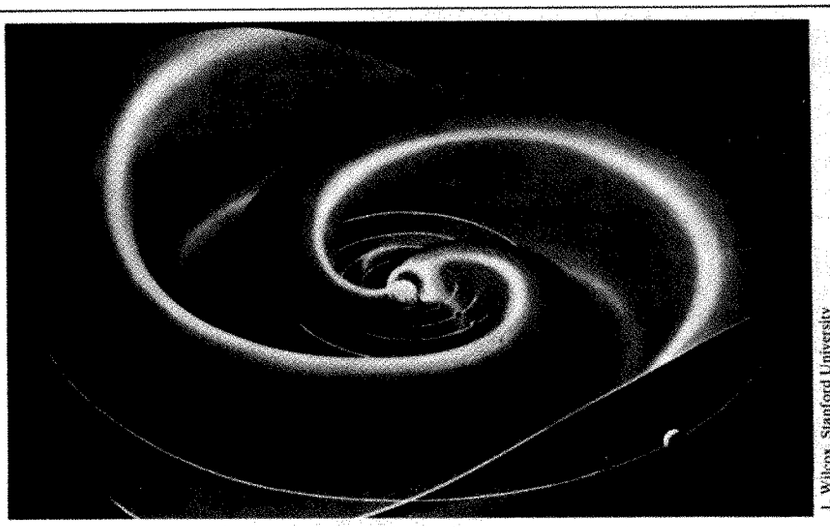
Of the 12 authors, seven contributed to the first edition and have attained somewhat variable success in bringing their essays up to date. All five new contributors have maintained the high standards set in the first edition. In his introductory chapter, Harris gives a clear outline of Scottish geological development, much enhanced by his table of events (Fig. 1.2). It is unfortunate that the sections on Tertiary growth and on geomorphic evolution (present in the first edition) have disappeared; these are relatively neglected fields that should not be ignored.

The presentation and standard of editing is, in general, so good that it is perhaps unnecessary to stress the few failures. A stronger hand might have removed some hangovers from the first edition, such as the multiple discussions of the Highland Border Group (presented separately on pp. 84, 98 and 109–110) and of the Ballantrae Volcanic Group (pp. 110, 152 and 174–175). The editor might also have established some standardization of such a crucial term as "Caledonian Orogeny", where Scottish geologists should give a clear lead. Now we know that many orogenies extend over long periods of time (few are short-lived as Stille thought), we badly need to get our definitions sorted out.

One achievement of the book is that diverse parts of geology have been brought together to form a coherent unity, although this does break down in a few places. The new contributions by Brown and Mykura respectively provide excellent summaries of Devonian magmatism and stratigraphy, as do the chapters by Francis on the Carboniferous and by Lovell on the Permian and Triassic, but it is a pity that these accounts of the Late Palaeozoic igneous rocks and sediments have not been more closely integrated.

The contribution by Emeleus on Tertiary igneous rocks contains clear reviews of the latest work in geochemistry relevant to petrogenesis. This chapter takes cognizance of recent geophysical studies, though in general geophysics is not well discussed throughout the book — such a failing is to be regretted, especially in view of much recent work on the deep geology of Scotland.

Sissons gives a brief summary of the complex developments in Scotland during the Quaternary. His ability to condense a large amount of data becomes evident by study of another new contribution to Scottish geology, *Scotland's Environment During the Last 30,000 Years.* The author, R.J. Price, states (p.23) that:



> This book is concerned not only with the geomorphological and marine sedimentary record but with the broad environmental changes which can be identified as a result of detailed investigations not only in these fields but in all aspects of the geomorphological, stratigraphical, palaeontological and archaeological record.

Price lives up to his claim in discussions of geomorphology and chronology, but some geologists will find him weak on sedimentology.

Price emphasizes a most important geological truth (pp. 8–11): the record is best in the oceans, where sedimentation has been more or less continuous; it is next best on the shelf, then on coasts and low ground, but it is almost non-existent in mountains. As a result, the key to many recent advances in Quaternary stratigraphy lies on the sea floor. Will river terraces be the next sediments to repay renewed investigation? They have produced many good results in the English Midlands; could they not also do the same in Scotland?

Both books reviewed here are clearly presented and well illustrated, with full lists of references. They should prove useful to a wide readership: the scientist, the student and the scientifically orientated tourist. Scotland has still further significant contributions to make to geology, and these two books will help to provide a sound basis for future work. □

W.S. McKerrow is a Lecturer in the Department of Geology and Mineralogy at the University of Oxford, and a Fellow of Wolfson College.

J. Wilcox, Stanford University

An artist's conception of the interplanetary medium out to the orbit of Jupiter, showing the spiral structure of the interplanetary magnetic field and the wavy shape of the interplanetary neutral sheet. (The neutral sheet, which is invisible, divides magnetic field lines pointing towards the Sun from those pointing away.) The illustration is taken from *Astronomy from Space: Sputnik to Space Telescope*, edited by James Cornell and Paul Gorenstein, and recently published by MIT Press. Price is $17.50, £15.75.

Announcing the new current-awareness journal from Cambridge

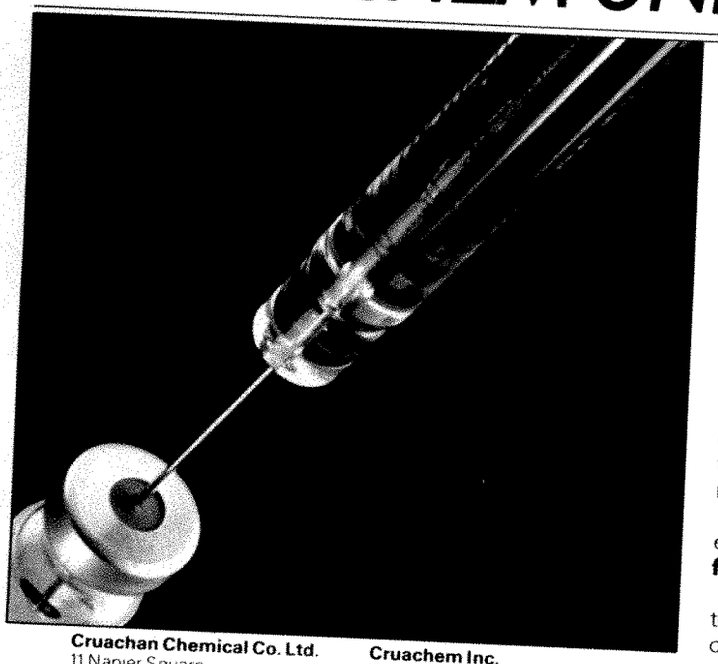
New for 1984

BIO/ESSAYS

Editor-in-chief: **Dr W.J. Whelan** *University of Miami*

Cambridge University Press is pleased to announce this important new monthly which will be launched in July 1984 and published for the ICSU Press, the publishing house of the International Council of Scientific Unions.

BIO/ESSAYS meets the demand for a current-awareness journal devoted to reviews, comment, debate and progress in the frontier areas of molecular, cellular, and developmental biology and their impact on science and society.



Whilst BIO/ESSAYS will concentrate primarily on advances in knowledge from basic research, it will also pay significant attention to actual or potential applications in medicine, industry and agriculture and is of particular interest to those working, or planning a career, in this field. It will debate speculative or controversial aspects of biological research, and disseminate authoritative views and exchanges of views.

Please contact Aileen Askwith, Journals Publicity Controller, for further information.

CRUACHEM ONE-SHOT PACKS

The Cruachem SPS-grade range of intermediates s new standards of purity and proven performance in DNA synthesis.

Now, these materials are available in pre-weighed, pre-dried ONE-SHOT PACKS.

Each septum-capped vial is packed under Argon an contains the appropriate quantity of material for a single nucleotide addition cycle in a synthesis on a 5 micromolar scal

Now there's no need to waste time weighing out an drying intermediates before your synthesis gets under way.

Keep a stock of these packs in your freezer and you synthesis start-up time is reduced to a few minutes. Couplin efficiency is unimpaired after six months storage at -20°C.

SPS GRADE SOLVENTS are also available packed under Argon in septum-capped bottles for direct connectior to your synthesis system using syringe-needles, eliminating the need to pre-dry and distill solvents and top-up solvent bottles.

The Cruachem SPS-GRADE range has been expanded to include deoxy-Uridine intermediates and **functionalised Controlled-Pore Glass supports.**

Like all SPS Grade materials, these are individually tested in an actual oligonucleotide synthesis before passing our Quality Control.

MONOCLONAL ANTIBODIES, ANTI-HUMAN, ANTI-ANIMAL ANTISERA.

SEROTEC has emerged within a very short time as one of the leading suppliers of quality monoclonal antibodies and polyclonal antisera in the world.

We are therefore pleased to announce the introduction of a hundred and fifty new products to the already comprehensive Serotec range.

If you would like further information on the expanding range of Serotec products, and you are not already on our mailing list, apply now for our new 1984 catalogue.

SEROTEC LTD
Station Road, Blackthorn, Bicester, Oxon OX6 0TP.

Equipment for microbiology

This week's selection of new products covers all those that would be used in a microbiology laboratory — from reagents to immunoassay kits.

Biologicals

● Endothelial cell growth supplement (ECGS) is now being supplied by Stratech Scientific. ECGS has been shown to replace feeder cell layers in clonal growth of hybridoma and other cell types. It shows consistency in growth-promoting activity, simplifies culture maintenance and is free from detectable bacteria, fungi and mycoplasma. It is supplied in a lyophilized form which is stable for 2 yr at 4°C. One vial, containing 15 mg, will supplement up to 300 ml of medium.
Circle No. 100 on Reader Service Card.

● Advanced Laboratory Techniques has now added a number of fluorescein (FTC) labelled compounds to its reagent range. These compounds are immunoreactive and intended for use in immunoassay systems. Included in the FTC-labelled range are: amikacin, carbamazepine, digoxin, human placental lactogen, phenobarbital, phenytoin, L-thyroxine and tobramycin. Most of these compounds may be conjugated to various alternative fluorescent labels.
Circle No. 101 on Reader Service Card.

● Amersham has added six new restriction endonucleases and one new modifying enzyme to its range of restriction and modifying enzymes. The additions are: *Acc* II (isolated from *Acinetobacter calcoaceticus*); *Ava* I (isolated from the blue green alga *Anabaena variabilis*); *Ava* II (isolated from the blue green alga *Anabaena variabilis*); *Dra* I (isolated from *Deinococcus radiophilus*); *Eco* RV (isolated from *Escherichia coli* J62 pLG74) and *Sac* I (isolated from *Streptomyces achromogenes*). The modifying enzyme is DNA polymerase I from *E. coli*.
Circle No. 102 on Reader Service Card.

Anglian Biotechnology has asked us to make an addition to our report on avian myeloblastosis virus (AMV) reverse transcriptase (see *Nature* **307**, 196). They would like us to point out that the product is manufactured using a technique pioneered by the president of Molecular Genetic Resources, Dr G.E. Houts, and that any queries involving AMV reverse transcriptase should be directed to Molecular Genetic Resources Inc., 6201 Johns Road, Suite 8, Tampa, Florida 33614, USA.

● A range of specific protein rich media is now available from Advanced Laboratory Techniques. The media are suitable for the preparation of serum standards for immunoassay or as a source material for the preparation of protein. The following are immediately available: C-reactive protein (CRP), liver ferritin, placental lactogen (PL) and thyroxine-binding globulin (TBG). All the media are supplied freeze-dried and sold as weight of specific protein. Small samples are available for evaluation.
Circle No. 103 on Reader Service Card.

● Two new mounting media, hydramount and dimethyl hydantoin formaldehyde resin, have been added to the BDH Gurr range of stains and microscopy materials. Hydramount is a fast-drying aqueous mounting medium which has adhesive properties when set so that the problems of specimen damage resulting from movements of the coverslip are minimized. Hydramount is suitable for botanical and zoological applications. It has a refractive index of 1.4668 and a viscosity of 4.71 cP at 20°C. It is designed for use in micro-entomology or in the preparation of aquatic micro-invertebrates. Dimethyl hydantoin formaldehyde resin (DMHF) is a water-soluble resin for mounting whole or dissected entomological material. It is designed for use in preparing taxonomic specimens for reference collections.
Circle No. 104 on Reader Service Card.

● An improved version of the microbore valve has been introduced by Rheodyne. The new model features 0.2, 0 5 and 1 μl chambers, a 0.13 mm diameter outlet passage and a built-in syringe needle part with 0.3 μl hold-up volume. The previous microbore valves (7413, 7410) are still available, but the 7520 is designed to replace them in areas of microbore HPLC where sample size is critical.
Circle No. 105 on Reader Service Card.

● Colony stimulating factor and human interleukin 2 are now being produced by Genzyme Koch-Light. Colony stimulating factor (mouse), colony stimulating factor (human) and interleukin 2 (human) can all be supplied. The new lymphokines add to Genzyme's existing range of research biologicals — interleukin 1 (mouse), nerve growth factor (human) and collagen II (chicken).
Circle No. 106 on Reader Service Card.

● The new hand-held UVX Radiometer from UVP has three interchangeable UV sensors. Each sensor has a 36-inch electrically-shielded cable enabling accurate readings from inaccessible locations. Designed for general use within UV-A, UV-B and UV-C wave bands, the sensors come equipped with filters to reduce the solarization characteristically associated with 254 nm UV sensors. The UVX Radiometer features direct digital readout, automatic test circuitry and a read–hold switch.
Circle No. 107 on Reader Service Card.

● RNasin is now available from Anglian Biotechnology. RNasin is purified by Promega Biotec and can be used in *in vitro* translation systems using rabbit reticulocyte lysate and in cDNA work using avian myeloblastosis virus reverse transcriptase.
Circle No. 108 on Reader Service Card.

● Two new endoglycosidases are available from Boehringer Mannheim Biochemicals for use in structural studies of glycopeptides and in the removal of sugars from glycoproteins. These glycosidases show very different specificities although both should be used in studies where specific cleavage of glycopeptides or glycoproteins is desired. Endoglycosidase D is specific for the digestion of complex sugars, while endoglycosidase H is useful for the digestion of high-mannose chains.
Circle No. 109 on Reader Service Card.

● Beckman has announced an addition to its range of Ready-Solv scintillation counting cocktails. The new CP extended clear-phase cocktails solubilize aqueous samples for counting. The cocktails hold up to 33% of most aqueous samples as a continuous clear liquid emulsion from neat to maximum capacity with no two-phase breaks. It will count the standard sample size of 1 ml in miniature counting vials. It can also be used for the elution of samples in filter counting techniques and for high protein content samples. Ready-Solv CP can be used in any liquid scintillation counter.
Circle No. 110 on Reader Service Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Service Card bound inside the journal.

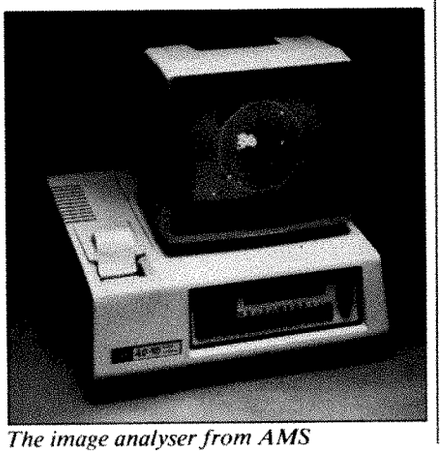
General laboratory equipment

●The MSJ-T series of fermentors from Bioengineering Associates automates the production of large batches of plant or animal cell cultures. The fermentors are designed for use with cell suspensions or microcarrier beads. Models are available in vessel sizes of 10, 20, 30, 40, 50, 70 and 90 litres. The system is controlled by the microprocessor-based Bioprocessor which automates control of *p*H, dissolved oxygen and temperature. It also runs steam sterilization of the vessel and the medium. Twelve analog and eight digital input ports are available. A computer can be added via the RS232 serial port or the optional IEE-488 interface bus. In addition to the MSJ series, Bioengineering Associates can supply the MD series of bench top fermentors which are offered in five vessel sizes from 1.2 to 10 litres.
Circle No. 111 on Reader Service Card.

● Four new thermostatic water baths are available from PolyScience. The units feature a durable polypropylene tray equipped with a heater, circulating pump and a temperature control circuit. The operating range is from ambient to 50°C with a control accuracy of ±0.1°C. These baths are useful in chemistry, biology and photographic laboratories as well as blood bank applications.
Circle No. 112 on Reader Service Card.

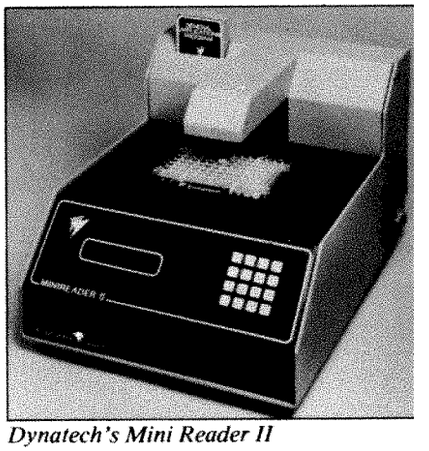
● AMS (Analytical Measuring Systems) has announced the release of a new image analyser to augment its existing system III and VIDS ranges. Called 40-10, the instrument is specifically designed for routine laboratory use. Applications include fluorescent bacteria counting, colony counting, area fraction measurements, diffusion zone area measurements, porosity and cell counting. The system is microprocessor-controlled and includes a built-in printer. The detector is digital, giving 256 grey level settings, and there is an automatic detection system.
Circle No. 113 on Reader Service Card.

● Hybritech has released the Gamma-Photon system for isotopic immunoassays. The solid state 24-well counter allows sample throughput of 500 tubes per hour, and provides for automated data reduction using a Hewlett-Packard model 87XM computer. The instrument offers data reduction software which gives data reduction of Hybritech's immission rate measuring apparatus format solid-phase monoclonal antibody-based Tandem-R immunometric assays. Gamma-Photon also includes data reduction routines for conventional competitive-binding radio-immunoassays, and for screening assays including hepatitis tests and pregnancy tests.
Circle No. 114 on Reader Service Card.



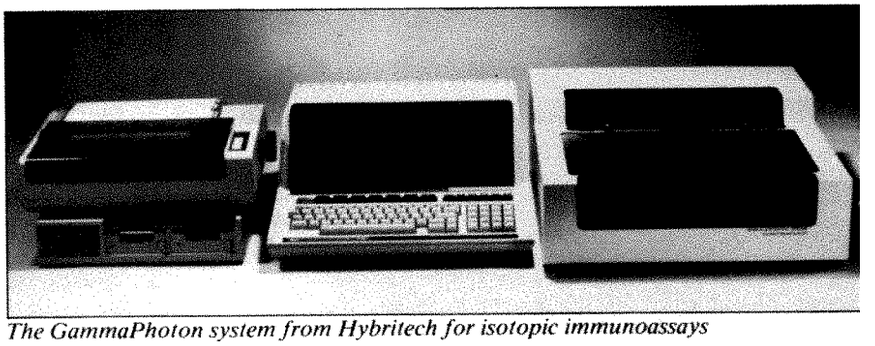
● The Titer-Pak from Robbins Scientific consists of a plastic box with telescoping cover. This contains a removable 96-hole rack which is pre-loaded with pipette tips. It is designed for use with multi-nozzle and standard pipettors. The complete Titer-Pak is disposable and is made of autoclavable polypropylene. It is also available sterilized by radiation.
Circle No. 115 on Reader Service Card.

● A three-dimensional hydraulic microdrive has been introduced by Medical Systems. The MO-103 is small and features a driving actuator which is remotely located from the headstage. Axes *x*, *y* and *z* can be driven smoothly through a cubic centimeter without zigzagging or limping. Control knobs are graduated in steps of 2 μm.
Circle No. 116 on Reader Service Card.

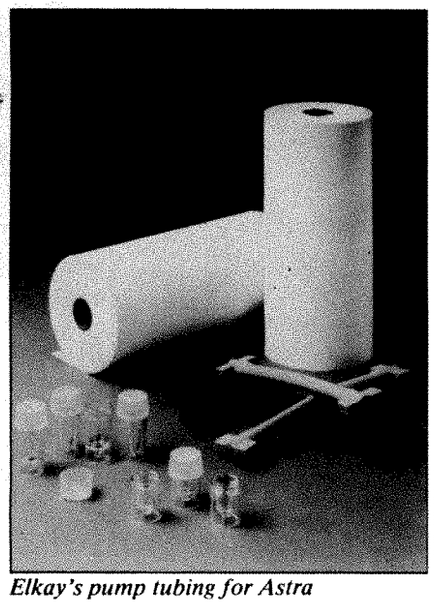


● The new Harris Lo Temp 16-V upright freezer has a capacity of 16 cubic feet divided into five chambers. Each chamber is fitted with an insulated, magnetically-sealed sub-door. The freezer is designed for life sciences, pharmaceutical and blood applications and comes in three models: −40, −70, or −85°C low temperature point. Standard on all models are casters and a safety handle and options include air or auxiliary water cooling and a standby CO_2 system.
Circle No. 117 on Reader Service Card.

● Heraeus has introduced three new types of tissue culture dish to the British market. Flexiperm is a reusable culture vessel made of silicon rubber. Its lower surface adheres to all smooth surfaces to form containers for cell culture. Two containers are available: Flexiperm slide which is designed for use with 76 x 26 mm microscope slides and Flexiperm disk which is normally used in conjunction with a Petriperm culture dish. The Quadriperm is a rectangular cell culture dish with four subdivisions in which cells may be cultivated on standard 76 x 25 mm microscope slides.
Circle No. 118 on Reader Service Card.



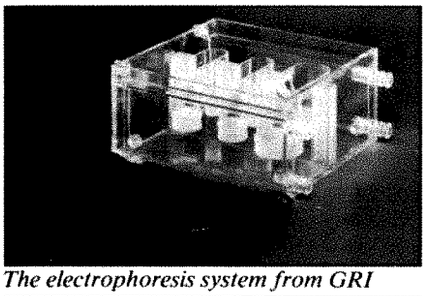
● The Mini Reader II is a manual ELISA reader produced by Dynatech which is coupled to a printer. It incorporates a plug-in cartridge programming system. A 96-well micro-ELISA plate can be read by the instrument and the results printed in approximately 2 min. The machine can store a series of readings and will print these readings when required in either a tabular format, a matrix showing positive and negative values or in optical density readings. In addition, the Mini Reader II provides a visual display of readings, well-by-well, with the results shown on the LED display. The machine has an integral keyboard for data entry which permits the user to select blanking on any well of the plate or number of wells in addition to permitting other data entry requirements such as stored information on print or demand used in conjunction with the program cartridges.
Circle No. 119 on Reader Service Card.



The image analyser from AMS

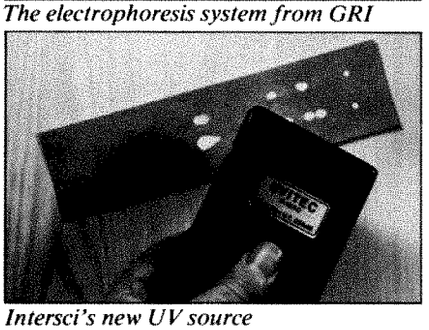
Dynatech's Mini Reader II

The GammaPhoton system from Hybritech for isotopic immunoassays



Elkay's pump tubing for Astra

● With the introduction of new Elkay pump tubing for use with Beckman Astra analysers, there is now an alternative single source for plastic consumables for Astra instruments. The silicone tubing is packaged in a press snap lidded polystyrene box.
Circle No. 120 on Reader Service Card.

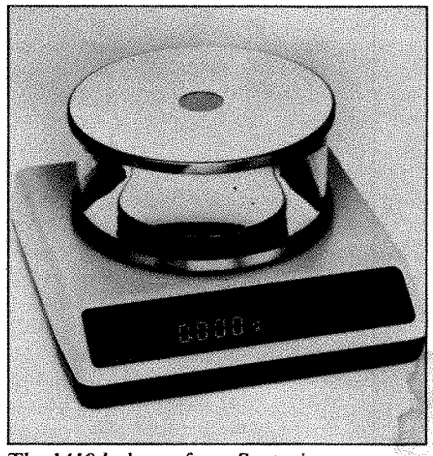


● LDC/Milton Roy has released two new versions of the spectroMonitor, model 1204A, variable wavelength detector. One version includes a maxN series fluid cell and a digital absorbance display. The standard version of the spectroMonitor III detector includes a 1,000 p.s.i. high pressure fluid cell and an analog absorbance display. The spectroMonitor III baseline drift is 5×10^{-4} A h^{-1} after suitable warm-up. The new versions of the spectroMonitor III detector feature a linear sensitivity range of 0.001–2.0 A full scale.
Circle No. 121 on Reader Service Card.

● A new range of pharmaceutical and laboratory autoclaves has been introduced by Edwards High Vacuum. The Edwards Fedegari series FOF autoclaves use the dynamic steam principle of sterilization and have a microcomputer control system dedicated to this sterilization process. There are 24 types of cycle available. Each cycle type must be further programmed by the user with the parameter values required to produce the final programmed cycle.
Circle No. 122 on Reader Service Card.

● A new range of UV/visible spectrophotometers, has been introduced by Pye Unicam. The PU8600 series of microprocessor/keypad-operated instruments is headed by two main versions–the PU8600, designed for industrial and teaching applications, and the PU8610 intended for use in the life sciences. A range of new accessories has also been produced.
Circle No. 123 on Reader Service Card.

The electrophoresis system from GRI

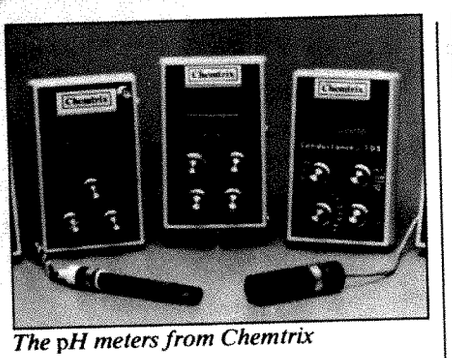


Intersci's new UV source

● Genetic Research Instrumentation has developed an electrophoresis system that is designed for the elution of protein samples from gels and the concentration of macromolecules in solution. The concentrated protein may be harvested either as a concentrate solution or bound to specific activity membranes. The system is based on its sample elution wells. These are two cylindrical wells which are bound to each other by a short bridge. The bottom of each well is covered by a membrane. Proteins migrate from one cup to the other under a constant electrical field of 5W within 1 h, either as a solution or bound to the membrane. Up to three samples may be processed simultaneously and two sizes of sample wells are available. The chamber is water-cooled and supplied complete with three sample wells, blank spacers, safety lid and input leads.
Circle No. 124 on Reader Service Card.

● Intersci has introduced a small but powerful UV source that is suitable for examining thin layer chromatography plates. The Uvitec Micro is available in short wave (254 nm) and long wave (365 nm) versions and comes complete with batteries and viewing box.
Circle No. 125 on Reader Service Card.

● Two new Tissue-Tek vacuum infiltration processors are available from Miles Laboratories. These are microprocessor-controlled flow-through tissue processors that automatically perform the tasks of fixation, dehydration, clearing and paraffin-impregnation of tissue. The specimens are safely inside a completely enclosed retort during processing. The processors are available in new 100- and 200-specimen capacity models as well as the original 300-specimen size. They incorporate a control pad which enables the operator to prepare and store up to 10 different processing programs.
Circle No. 126 on Reader Service Card.



● Coulter Electronics has introduced a new multi-parameter discrete chemistry analyser, Dacos. It can analyse any sample, at any time, with a throughput of 450 tests per hour, carrying out single tests, profiles and statistics. It houses a multi-wavelength optical bench, which rotates around a ring of reaction cuvettes to provide continuous absorbance readings at up to eight wavelengths every 8 s. Dacos uses low sample and reagent volumes with a minimum reaction volume of 120 μl. It uses reusable reaction cuvettes to keep consumable costs down. One or two reagents may be added and both sample and reagent blanks are taken during the analysis.
Circle No. 127 on Reader Service Card.

The 1419 balance from Sartorius

● Brinkman Instruments has introduced the Sartorius series 1400 milligram balances. The series includes the model 1405 MP8 (220-g capacity, 0.001-g read ability) and the dual-range models 1412 MP8 and 1419 MP8 (30 to 300-g and 60 to 600-g capacities, respectively, and 0.001 and 0.01-g readability). The quad-range model 1475 MP8 (420-g capacity) features a fine reading of 0.001 g which can be activated anywhere within the weighing range by pushing the tare button. Additional readabilities of 0.002, 0.005 and 0.01 g are automatically displayed at predetermined levels. Additional features include display control of the last digit (always on, always off, or automatically controlled), auto-adjustable display update speed, adjustable digital filter, seven-segment digital display with stabilized readout indicator, automatic electronic calibration and full-range electronic tare. All models come with a stainless steel and glass draft shield.
Circle No. 128 on Reader Service Card.

● The new Elkay XLDG macropipettor with digital capacity selection dispenses volumes from 1 to 5 ml with adjustable 500 μl increments to within ± 0.4% reproducibility. It also has a hexagonal body, feather touch plunger action, positive click-stop, digital capacity adjustment and colour-coding to ensure correct tip usage.
Circle No. 129 on Reader Service Card.

The pH meters from Chemtrix

Wheaton's Unispense/Omni-Pette

● Wheaton Instruments has introduced the Wheaton Unispense/Omni-Pette, an automatic liquid delivery system for aliquoting as well as aspirating. A feature of the system is the Omni-Pette remote control dispensing head which allows fluids to be delivered at some distance from the pump. The Wheaton Unispense/Omni-Pette will feed, wash and innoculate cells in 90 and 24-well microtest plates when the appropriate microtest manifold is attached to the Omni-Pette. The Wheaton Unispense /Omni-Pette is suited to delivering small volumes of fluid in the 0.1 to 20 ml range. The system is controlled manually by a push button, foot switch or by the flush-mount switch. When programmed in the automatic mode, the Unispense/Omni-Pette will cycle at regular intervals which can also be programmed for 0.5–5 s delay intervals between cycles. A five-digit LED display records the number of doses dispensed, while a cycle alert signals the end of each dispense cycle.
Circle No. 130 on Reader Service Card.

● Cytogard is the newest addition to Gelman Sciences' laminar flow units. It has been designed to allow the safe handling of cytotoxic drugs. The cabinet, manufactured in compliance with Australian standard AS 2567, the only legislative standard in the world for the handling of cytotoxic drugs, is also designed to satisfy British standard 5726 class II for containment. The construction cabinet has a stainless steel working area. It also includes a pre-filter and final high efficiency particulate air (HEPA) filter for maximum protection and a carbon absorption cell for handling volatile liquids.
Circle No. 131 on Reader Service Card.

● A new family of multi-function *p*H meters has been produced by Chemtrix. The model 410 *p*H and mV meter is accurate to ±0.1 *p*H and ±0.1% mV units. When temperature is crucial, the model 420 *p*H/mV meter automatically compensates for sample temperature variations over the 0–100°C range. In addition to this the model 430 *p*H/mV/temperature meter measures temperature over the 50 to 200°C range with ±0.5°C accuracy. All units have large LCD displays. They are battery powered and operate over the 0–14 *p*H and ±1,999 mV ranges.
Circle No. 132 on Reader Service Card.

● Brinkmann Instruments has released the Epson HX-20 system for Sartorius electronic balances. The system includes an Epson HX-20 computer; an interface for connection to Sartorius MP6, MP7 or MP8 electronic balances and standard programs for statistics, net weight or counting. The HX-20 computer is small enough to fit in a briefcase and requires no power cord.
Circle No. 133 on Reader Service Card.

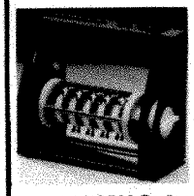
● Tissue-Tek III uni-cassettes, Tissue II cassettes and Tissue-Tek embed rings are now available from Miles S tific in a selection of colours. Uni-cas are available in five new colours: tan, orange, gold and aqua, in addition t original five colours: white, pink, g blue and yellow. The Uni-cassette s also includes a biopsy cassette for specimens, which is grey. Mega-cass available for larger tissue speci Tissue-Tek II cassettes are also availa the same 10 basic colours as Uni-cas but there is also a clear, polypro cassette that allows embedded tissue seen. Tissue-Tek embedding ring available in colours for the first time being white, pink, blue, green and y The rings allow larger specimens embedded than does Mega-Cassette
Circle No. 134 on Reader Service Ca

● Futura II star-series refillable cc ation electrodes from Beckma designed to measure *p*H in di situations. These include those in ionic strength is low, such as in ac and drinking water, those where t ature varies substantially or in s which are sensitive to silver. Sta electrodes operate in the range of *p* 14 and are accurate to ±0.01 *p*H. Re time in the *p*H 4 to 7 range at c temperature is stable to ±0.02 *p*H For temperature changes from 2 75°C in *p*H 4 buffer, response is st ±0.02 pH in 30 s. Slope is 97 to temperature range is 5 to 100°C a thermal point is 7 *p*H.
Circle No. 135 on Reader Service C

Literature and assay kits

● A new test for serum creatinine is now available from J.T. Baker Chemicals. In cooperation with Dutch clinical laboratories, J.T. Baker has developed a creatinine test based on the Jaffé method but free from bilirubin interference. Bilirubin, by use of a special reagent, is oxidized before the reaction rate is measured. The test has been designed for the kinetic measurement of creatinine. Application sheets currently available include Cobas Bio, RA-1000, PA-800 and manual techniques.
Circle No. 136 on Reader Service Card.

● Boehringer Mannheim Biochemicals now offers an *in vitro* immuno-turbidimetric test kit for the determination of fibronectin levels in human plasma. The turbidity, which results from the antigen–antibody reaction, is measured with a spectrophotometer. The assay uses a standard curve obtained from the set of standards included in the kit. Sample values are compared to this and the plasma fibronectin levels are then determined. The shelf life has been extended and the kit may now be stored at 4°C.
Circle No. 137 on Reader Service Card.



● A new ^{3}H RIA kit is now availat Seragen for specific measuren prostaglandin E_1 (PGE_1). This 100- contains all the necessary reagents test, including antisera specific fc which show 9% cross-reactic PGE_2. Seragen's new PGE_1 a sensitive to 20 pg per 0.1ml.
Circle No. 138 on Reader Service C

● An instructional brochure available from Tago that descr structure and function of plasi proteins in the transport of cholest triglycerides. Other topics covere brochure include the clinical sig of apolipoprotein measurements immunoassay systems and po studies using Tago's Diffu-Gen k
Circle No. 139 on Reader Service

● A new brochure is availat Boehringer Mannheim Biochemi brochure contains a complete list molecular biology products, modifying enzymes, restriction linkers and primers, inhibitors, nu and nucleosides.

DIANORM -GD-1 new!
5-Cell Equilibrium Dialyzer
for (ligand) binding and distribution studies under standardized conditions.
5 different DIANORM® – rotating-cell-types (PTFE) are available: minimal volumes 0.125, 0.6, 0.7, 1.5, 3.0 ml. Equilibrium reached in 15-180 minutes. Voltage of the drive is transformed down to 14 V thereby avoiding any risk when using a temperature controlled water bath.

DURHAM UNIVERSITY

SENIOR RESEARCH ASSISTANT IN SYNCHROTRON RADIATION RESEARCH

plications are invited for the post Senior Research Assistant tenable he Physics Department for two rs from early 1984. The successful licant will work, under the super- on of Dr.B.K.Tanner, on an .R.C. supported project to elop X-ray diffraction techniques he characterization of strains in V semiconductors. Part of the k will be carried out on the chrotron Radiation Source at esbury Laboratory.

nitial salary in the range £7630 — 30 on National Range 1A plus rannuation.

pplications (3 copies) naming e referees should be sent by 2 ch 1984 to the Registrar, Science oratories, South Road, Durham 1 3LE, from whom further iculars may be obtained. (1255)A

THE UNIVERSITY OF TEXAS HEALTH SCIENCE CENTER AT SAN ANTONIO DENTAL SCHOOL

ASSOCIATE DEAN FOR RESEARCH AND ADVANCED EDUCATION

Academician and scientist to fill position in an innovative and expanding dental school. Responsibilities include organization and supervision of an active school wide research program and coordination and administration of dental school post-doctoral programs. The position also offers an opportunity to develop independent research activities. D.D.S. or D.M.D. and advanced degree preferred.

Send curriculum vitae to Dr. Richard Carr, Dental Dean's Office, 7703 Floyd Curl Drive, San Antonio, Texas 78284. The University of Texas Health Science Center is an equal opportunity/affirmative action employer. (NW317)A

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL (University of London)

RESEARCH ASSISTANT IN HOMINID PALAEONTOLOGY

Applications are invited from graduates to assist in the analysis of hominid dental remains. Previous experience with computing and multivariate statistical techniques would be an advantage. The appointment is funded by the NERC for two years. Salary within the scale £6,311 — £8,531 plus £1,186 London Allowance.

Further particulars should be obtained by applying in writing to Professor Bernard Wood, Department of Anatomy and Biology as Applied to Medicine, The Middlesex Hospital Medical School, Cleveland Street, London W1P 6DB (01-636 8333 ext 7179). Applications, with the names and addresses of two referees, should reach the above by 16 March 1984. (1272)A

UNIVERSITY OF NOTTINGHAM FACULTY OF AGRICULTURAL SCIENCE

Applications are invited for the position of Research Assistant/Fellow to join a group interested in the growth of animals to study the control of muscle protein deposition in ruminants. Suitable applicants will have a higher degree in Biochemistry, Physiology or Agricultural Science. Experience in animal cell tissue culture would be an added asset. Funds are being provided by the Agricultural Research Council, initially for a period of one year.

Applications, naming two academic referees, should be addressed to Dr P J Buttery, Department of Applied Biochemistry and Food Science, University of Nottingham School of Agriculture, Sutton Bonington, Nr Loughborough, Leics LE12 5RD, to arrive as soon as possible. Informal enquiries on Kegworth (05097) 2386 would be most welcome. (1275)A

COLD SPRING HARBOR LABORATORY

Post-Doctoral Research Positions in Molecular Biology, Cellular Biology, and Neurobiology

Applications are invited for post-doctoral positions with the following Cold Spring Harbor Laboratory Staff:

- **David Beach** — Cell cycle control genes in yeast.
- **Susan Bonitz** — Regulation of yeast mitochondrial genes by nuclear gene products.
- **Ed Harlow** — Molecular analysis of viral and cellular tumor antigens.
- **Susan Hockfield** — Studies of the nervous system using recombinant DNA and hybridoma technology.
- **H. Earl Ruley** — Molecular analysis of oncogene function.
- **Pablo Scolnik** — Insertional mutagenesis in prokaryotes. Primary structure of promoters in phototrophic bacteria.
- **Bruce Stillman** — Eukaryotic DNA replication and adenovirus molecular biology.
- **Douglas Youvan** — Molecular genetics and biophysics of the bacterial photosynthetic apparatus.
- **Mark Zoller** — The study of DNA/protein interactions in yeast using *in vitro* mutagenesis.

Applications and inquiries should be directed to the specific staff member of interest. **Cold Spring Harbor Laboratory, Cold Spring Harbor, New York, 11724.** Cold Spring Harbor Laboratory is an Affirmative Action/Equal Opportunity Employer.

(NW310)A

GROUP LEADER MOLECULAR BIOLOGY

Unigene Laboratories, Inc., a multidisciplinary biotechnology research corporation, is seeking a distinguished scientist for the position of Group Leader in Molecular Biology. The successful candidate will have 5-10 years of post-Ph.D. research experience and an outstanding publication record demonstrating a broad background in all aspects of molecular biology. Scientific creativity and superior professional credentials are prerequisites, as the individual will be responsible for supervising and troubleshooting a team of senior and junior staff. Previous experience as a Group Leader, Project Leader or Principal Investigator in Molecular Biology is essential, while industrial experience is desirable but not required.

Unigene is a sharply-focused, financially secure institution utilizing Molecular Biology, Immunology, Protein Chemistry and Organic Chemistry to conduct state-of-the-art research in the field of human health care. Our ultra-modern research facility is located in Fairfield, New Jersey. The company offers an excellent salary and comprehensive benefits package, including equity participation, along with the opportunity to work in a stimulating research environment which fosters continuing professional development.

For a challenging and rewarding opportunity to participate in the rapidly expanding health care field with a young and aggressive company, please send a CV and three references in confidence to:

Dr. Warren P. Levy
Unigene Laboratories
110 Little Falls Road
Fairfield, New Jersey 07006

unigene
An equal opportunity employer

UNIVERSITY OF ILLINOIS PROFESSOR OF CROP MOLECULAR GENETICS

An outstanding scientist is needed for a key position in the newly established CENTER OF EXCELLENCE IN CROP MOLECULAR GENETICS AND GENETIC ENGINEERING, funded in part by a grant from the Standard Oil Company (Ohio). We are seeking a molecular biologist experienced in using recombinant DNA techniques, to introduce useful genes into economically important plants such as maize and soybeans. Applicants should provide documentation of proven research experience and capability in genetic engineering and plant molecular biology. Appointment will be in the Department of Agronomy of the University of Illinois, with possible joint appointments in affiliated departments. A person hired at the associate or full professor level will be granted tenure. For the duration of SOHIO funding, the person will be designated the SOHIO Professor of Crop Molecular Genetics. Rank will be commensurate with qualifications and salary will be highly competitive.

The genetic engineering group in the University of Illinois Agronomy Department presently comprises five senior scientists in well-established research laboratories. Fifteen other University of Illinois scientists, working in molecular genetics and genetic engineering of higher plants, are identified as collaborators of the SOHIO-UI Center of Excellence.

In addition to establishing a vigorous research program, the successful applicant will be expected to cooperate with and provide expertise in support of existing research programs of the group.

Applications will be accepted until 15 April 1984 or until a suitable applicant is found. Submit curriculum vitae, a statement of research goals and teaching interests, a list of publications, and names, addresses and telephone numbers of five references to: Dr. T. Hymowitz, Department of Agronomy, University of Illinois, 1102 South Goodwin Avenue, Urbana, Illinois 61801 USA.

The University of Illinois is an Affirmative Action Equal Opportunity Employer.

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF BIOCHEMISTRY

LECTURESHIP

Applications are invited for the above position now vacant due to the appointment of Dr C R Lowe as the Director of Biotechnology in the University of Cambridge. The post will involve the teaching of Biochemistry and Biotechnology to science and medical students and the successful applicant will be expected to establish a research group for investigating fundamental biochemical problems and their applications. The applicant should have 2-4 years post-doctoral experience in addition to a postgraduate qualification in Biochemistry, Molecular Biology or Chemistry.

Salary scale: £7,190 — £14,125 per annum.

Further information about the above post and about the Biochemistry Department may be obtained from Professor K Akhtar, F.R.S. Department of Biochemistry, University of Southampton SO9 3TU.

Further particulars may be obtained from A J Small, Staffing Secretary, The University, Highfield, Southampton SO9 5NH, to whom applications (7 copies from applicants in United Kingdom and one from others) giving a brief curriculum vitae and names and addresses of three referees should be sent before 23 March 1984. Port Moresby
LECTURER IN BIOCHEMISTRY
P821004/84

pplications are invited for the ove position which will become cant in June, 1984, in the epartment of Human Biology in the aculty of Medicine. This epartment undertakes the pre-inical training of medical and ntal students in Biochemistry, natomy, Pharmacology and ysiology, and is responsible for st-graduate course in basic medical iences. Departmental and terdepartmental research is couraged. The successful applicant ll have had teaching experience in ochemistry to medical students; it is e aim of this Department to present e pre-clinical medical subjects in a nctional and clinically relevant ntext, and therefore a medical alification would be an advantage, would teaching/research perience in a developing country.

Salary: Lecturer II K17,870 per num plus gratuity; Lecturer I 6,020 per annum plus gratuity.

Applications including a full rriculum vitae, a recent small otograph and the names and dresses of three referees should be rwarded to the Deputy Registrar taffing), University of Papua New uinea, PO Box 320, University pua New Guinea, to reach him no ter than 30th March 1984. In order expedite the appointment ocedure, applicants are advised to k their referees to send confidential ports directly to the University thout waiting to be contacted. ndidates resident in the UK should nd an additional copy of their plication to the Association of ommonwealth Universities ppts), 36 Gordon Square, London C1H 0PF, from whom formation about conditions of rvice is available.
(W776)A

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified men and women for appointment to the following positions:

RESEARCH SCHOOL OF PHYSICAL SCIENCES
DEPARTMENT OF THEORETICAL PHYSICS
RESEARCH FELLOWS/ SENIOR RESEARCH FELLOWS

The Department (Head: Professor K J Le Couteur, FAA) conducts studies on nuclear structure and reactions, particles and fields, statistical mechanics, solid state physics and plasma physics. Preference in this instance will be given to applicants in theoretical nuclear physics or particle physics and field theory. Excellent computing facilities are available in the School, and interdisciplinary interaction with other groups in the School and in the University is encouraged.

Two posts are available and appointments will date from late 1984.

Closing date: 15 March 1984.

Conditions of Appointment: Salary will be in accordance with qualifications and experience within the ranges: Senior Research Fellow $A32,679 — $A38,980 pa; Research Fellow $A23,394 — $A30,734 pa. Current exchange rate is $A1 = UK 0.65p.

Appointment, unless otherwise stated, will be: Senior Research Fellow/Research Fellow normally up to three years with the possibility of extension to maximum of five years.

Grants are provided towards travel and removal. Assistance towards housing is given to an appointee from outside Canberra. Eligible appointees will be required to join the Superannuation Scheme for Australian Universities. The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should write to the Registrar of the University, GPO Box 4, Canberra, ACT 2601, Australian, or to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PE, for further particulars before submitting applications. (W775)A

UNIVERSITY OF ALBERTA

RESEARCH ASSOCIATE IN NEUROPHYSIOLOGY

DIVISION OF NEUROSURGERY

Applications are invited for the above position. Candidates must have a Ph.D. in Neurophysiology, state of the art skills and a good publications record. Should be enthusiastic about working with clinicians to apply basic science methods to medical problems such as epilepsy and pain. Send curriculum to Dr. Bryce Weir, 11-102 Clinical Sciences Building, University of Alberta, Edmonton, Canada T6G 2G3. (NW315)A

Leukaemia Research Fund Centre at the Institute of Cancer Research

A Leukaemia Research Fund Centre is being established at the Chester Beatty Laboratories of the Institute of Cancer Research in the Fulham Road, London. The Centre (Director: Dr. M. F. Greaves) will have a broad based programme of investigations on the cellular and molecular basis of human leukaemia.

Research Positions Available from 1st April, 1984

A. Post-Doctoral Research Fellowship:

A three-year post-doctoral research fellowship is available for studies on the biochemistry of membrane associated proteins of normal and malignant haemopoietic cells. Experience in immunochemistry and membrane protein analysis will be required. Salary on the MRC non-clinical scientific grades as appropriate depending on experience. **(Ref. 300/G/39)**

B. Research Assistants:

(1) Molecular Biology: A research assistant is required to help establish a molecular biology laboratory and to actively participate in its research programme. The latter will primarily concern studies of the regulation of proto-oncogene expression during haemopoietic growth and differentiation. **(Ref. 301/B/43)**

(2) Monoclonal Antibodies: A research assistant is required to be responsible for monoclonal antibody (hybridoma) production. Priorities in this area will be antibodies to cell surface associated receptors and proto-oncogene products. **(Ref. 301/B/44)**

(3) Flow Cytometry: A research assistant is required to be responsible for a flow cytometry section of the laboratory which will include a Becton Dickinson FACS IV (440), analyzer and computing facilities. Projects will include multi-parameter analysis and isolation of haemopoietic progenitor cells and new approaches to the immunodiagnosis of leukaemia. **(Ref. 301/B/45)**

Salary for these posts on the MRC research officer or technician scales as appropriate depending on experience and responsibilities to date.

Applications for any of the above posts should be sent with a full CV in duplicate **to the Personnel Officer, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting the appropriate reference number.** (1265)A

BIOGEN

A leading biotechnology company with laboratories in the US and Switzerland, is looking for its Geneva laboratories for

an IMMUNOLOGIST

with several years experience in the area of cell mediated immunity, T-cell hybridomas and lymphokines,

2 PROTEIN CHEMISTS

with experience in large scale protein purification and/or strong background in conformational studies of proteins,

a MICROBIOLOGIST

with extensive experience in fermentation research and development.

We offer a challenging scientific career with the opportunity to interact with talented colleagues in a stimulating environment. If this offer appeals to you, then reply to:

UNIVERSITY OF WAIKATO
New Zealand
MICROBIOLOGIST/ BIOCHEMIST/SOIL SCIENTIST
for work on
DENITRIFICATION BY RHIZOBIA
(Vacancy A 84/3)

A Research Scientist is required to continue work on a contract from the Ministry of Agriculture and Fisheries to investigate the role of rhizobial denitrification in soils. A postdoctoral worker is preferred, but other experienced researchers will be considered.

The work will involve the field and laboratory measurement of microbial denitrification, and experience in the use of gas chromotography as well as in soil microbiology or biochemistry, would be an advantage. The position may be taken up immediately and is for one year, with the possibility of a short extension. The salary for a postdoctoral candidate would probably be the equivalent of the top of the junior lecturer scale (currently NZ$18,732 pa) or the first or second step of the lecturer scale (currently NZ$21,660 pa and NZ$22,421 pa respectively).

Enquiries concerning the research should be made directly to Dr R M Daniel, School of Science, at the University of Waikato, Hamilton, New Zealand.

Applications should be made in a prescribed format which is available from the Registrar, University of Waikato, Hamilton, New Zealand, or from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Each applicant is asked to request his/her referees to write directly to the Registrar with a confidential report on the applicant's suitability for the position.

Applications close with the Registrar on 2 April 1984.
(W777)A

UNIVERSITY OF NOTTINGHAM
DEPARTMENT OF ZOOLOGY
LECTURESHIP IN ZOOLOGY

Applications are invited for a lectureship in the field of Animal Behaviour, especially from those with research experience is causal and/or developmental aspects of behaviour, to complement existing interests in behavioural ecology and evolution.

This appointment will be in the salary range £7,190 to £14,125 per annum and will start in September 1984.

Further particulars and application forms, returnable not later than 13 March 1984, may be obtained from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham, NG7 2RD. Ref No 923. (1268)A

THE UNIVERSITY OF TENNESSEE MEMORIAL RESEARCH CENTER (UTMRC)

invites applications for two tenu track positions at the assistant associate professor level. T UTMRC, a fully equipped biome cal research institute with excell small and large animal facilities, staffed by basic and clinical scienti with established programs in molec lar and cellular immunology, onc ogy, experimental hermatology, a pathology, including neuroscien Preference will be given to M.D. Ph.D. candidates who are capable developing independent resear programs that interface with those other UTMRC senior investigat and complement those of t academic clinical departments of University of Tennessee Memor Hospital. The successful applica will be provided core supp including salary and necessa laboratory start-up funds; it expected that additional resea support will be derived from grants other funding mechanisms. Invol ment in educational activities possible through participation in p and postdoctoral programs of University of Tennessee, the C Ridge National Laboratory, and the undergrduate and gradu medical education programs of University of Tennessee. Rank a salary are negotiable.

Interested parties are invited furnish their curriculum vitae and names and addresses of three re ences to: Emilio A. Machado, M. Chairman, Search Committ University of Tennessee Memo Research Center, 1924 Alcoa Hi way, Knoxville, Tenn. 37920. Affirmative Action/Title IX/Sect 504 Employer. (NW313)/

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF MEDICAL MICROBIOLOGY
RESEARCH ASSISTANT

A graduate is required to join a gr investigating the molecular basis Gonococcal infections. The work involve fractionation of biologic active macromolecules, immu chemical analysis with monocl antibodies and growth of cells tissue culture. Applicants sho have an honours degree in Bio mistry, Microbiology or a rel subject. The post is funded by MRC for three years commenci March 1984.

Salary will be on Grade 1B £6, — £8,530 per annum for Rese and Analogous Staff.

Further particulars may obtained by contacting Dr J Heckels, Southampton (0703) 777 ext 3918 or from Mr A J Sn Staffing Secretary, Univers Southampton SO9 5NH to wh applications (2 copies) should be giving date of birth, a full curricu vitae and the names and addresse two referees as soon as possi Please quote reference MA1 1284/AJS/N. (1267)

Head of Microbial Biochemistry Department

Greenford, Middlesex

An experienced research scientist is required to manage a multi-disciplinary department of about 40 scientists and technical staff.

The major disciplines in the department are biochemistry and microbiology. Research is at present concentrated on the search for selective techniques, often involving target enzymes, aimed at discovering novel biological activity of natural or synthetic origin. Current projects include work with bacteria, fungi and viruses and the design of automated assays to identify pharmacologically active agents. The department also includes ecology and fermentation groups which examine a diversity of habitats, for micro-organisms of possible biological or medicinal application and carry out studies to optimise the production of secondary metabolites.

The successful candidate is likely to be under 40 years and should have a proven innovative research record, together with administrative and communication skills, and the ability to motivate staff to a high standard of scientific achievement.

Major Company benefits include a Company car, profit sharing bonus scheme, non-contributory pension scheme and relocation assistance if appropriate.

Please write or telephone for an application form, or initially forward a full C.V. to: The Personnel Manager, Glaxo Group Research Limited, Greenford Road, Greenford,Middlesex. Tel: 01-422 3434 ext 2568, quoting ref: U/515.

IMMUNEX CORPORATION is a multi-disciplinary biotechnology company pursuing research and development of important immunoregulatory diagnostic and therapeutic products. An opening currently exists for a:

MOLECULAR BIOLOGIST

experienced in the expression of eukaryotic genes in microorganisms (bacteria and/or fungi.) A Ph.D. and post-doctoral experience is required. Knowledge of immunology is not necessary.

Please send a resume and the names of three references to:

Personnel Director
Immunex Corporation
51 University Street
Seattle, WA 98101

(NW324)A

immunex

Reproductive Biologist

Experienced embryologist with Ph.D. required to manage busy laboratory and devoted to both service and research of human infertility.

Facilities include a successful IVF programme (16 delivered infants to date) gamete and embryo cryopreservation, techniques for the study and treatment of oligospermia, the induction and intensive monitoring of ovulation and active research into the causes and treatment of early pregnancy wastage.

The laboratory has a nucleus staff of 3 biologists and 2 technologists and is linked to a large private Infertility Clinic with research undertaken in affiliation with the University of Western Australia. The successful applicant is expected to manage the laboratory, supervise research projects and liaise with the clinical staff to optimise patient management.

Salary negotiable in keeping with applicant's experience and expectations.

Apply by 31st March 1984 with detailed curriculum vitae to:
Dr. J.L. Yovich, Director, PIVET Laboratory, 442 Barker Road, Subiaco, Western Australia. Tel: 09-382-1677.

(W761)A

Maag

Dr. R. MAAG Ltd., A Swiss agrochemical company with research center in Deilsdorf/ Switzerland, has an opening for a

PLANT PHYSIOLOGIST

Applications are invited from individuals with a PhD degree in plant physiology and, preferably, with several years of experience in mode of action studies of herbicides. The successful candidate should be well acquainted with the plant physiological and biochemical methods to study the following pathways: Photosynthesis (photosystem I+II inhibition, electron transport, phosphorylation, CO_2 assimilation); respiration (O_2 consumption, ATPase inhibition); chlorophyl, carotinoid, lipid, DNA, RNA and protein synthesis. Experience in auxine physiology is an asset. Modern laboratories and equipment are available.

Applicants (Swiss citizens) should submit a Curriculum Vitae, a list of their publications, and the names of three references to Dr. R. MAAG Ltd., personnel department, 8157 Dielsdorf, Switzerland.

(W772)A

THE INTERNATIONAL CENTRE OF INSECT PHYSIOLOGY AND ECOLOGY
PO BOX 30772, NAIROBI, KENYA

DEPUTY DIRECTOR

(REF: SCI/83/7): Readvertisement

The ICIPE is an international institution headquartered in Nairobi, Kenya. It undertakes advanced research in insect science and post management, and offers high-level training to insect scientists and technologists from Africa and other developing countries. It has 40 senior scientists; and is funded by a consortium of donors comprising United Nations and international bodies, governmental aid agencies, and private foundations.

Applications are invited from highly qualified scientists and widely experienced research managers for the senior research management position of DEPUTY DIRECTOR at the ICIPE.

The Deputy Director reports directly to the Director of the Centre, and in his absence, acts for him. He will, in addition, have overall responsibility for the Research Division of the ICIPE, which includes the research programmes, research support units, and technical support services (including field station facilities); and maintain close liaison with supportive Divisions within the ICIPE (on Administration, Finance, and Communication and Training). The successful candidate will be a person with a solid research background in insect science or pest management or plant protection, he will have had considerable experience in science policy matters and research management; and he will be a successful internationalist able to work in an African environment. A more detailed job description will be sent to qualified candidates.

The renumeration package will be competitive, and will reflect the vital importance of this position within the ICIPE.

Applications, giving updated curriculum vitae and addresses of three referees should be addressed (in confidence) to: The Director, ICIPE, PO Box 30772, NAIROBI, Kenya.

Closing Date: 31st March 1984.

(W769)A

Postdoctoral position in field hydrology
Centre d'études nordiques
Université Laval, Québec

This position is available immediately (June 1st, 1984) for a researcher in field hydrology in the periglacial environment. Research topics concern snow, surface hyrdrology and permafrost thermal regime at study sites in northern Québec. The selected candidate will join an already existing group composed of a geophysicist, a geomorphologist and a botanist, which is involved in landforms and permafrost mapping along with the study of permafrost related ecological conditions. The post-doctoral researcher will have autonomy in the planning of his work and field instrumentation set-up as he will be a full member of the research group. Logistical support is provided within this context.

Although all members of the present group can communicate in English, the working and living environment is francophone.

This is a two year position. **Send curriculum vitae with summary of research interest and the name of three respondants. Reprints would be appreciated. Send to: Dr. Michel Allard, Centre d'études nordiques, Université Laval, Sainte-Foy, Québec, Canada, G1K 7P4.**

Applications are invited from all; *in accordance with Canadian immigration regulations applications from Canadian citizens and landed immigrants will be considered first.*

Bureau of Mineral Resources, Geology & Geophysics Australia

RESEARCH SCIENTIST/SENIOR RESEARCH SCIENTISTS

Marine Geophysicists

The Division of Marine Geosciences and Petroleum Geology in the Australian Bureau of Mineral Resources, Canberra, has vacancies for Marine geophysicists (3 positions).

The principal research aims of the Marine Division are to define the regional geological framework, petroleum prospectivity and evolution of the sedimentary basins of Australia's extensive continental shelf and margins; further to develop new scientific concepts of basin structures and evolution of passive margins and also the active margins of the South Pacific. The main objective is the stimulation of ongoing programs of offshore petroleum exploration. The Division is presently in the process of acquiring a research vessel and seismic processing centre.

The successful candidates should be experienced in multichannel seismic operations, in seismic structural and stratigraphic interpretation and in at least some aspects of geohistory analysis. Associated experience in other fields of marine geophysics and petroleum would be valuable but not essential.

Classification will be at Research Scientist or Senior Research Scientist level depending on the successful candidate's qualifications and experience.

Qualifications:
A PhD (or equivalent) in marine geophysics together with demonstrated research ability.

Salary:
Research Scientist (RS) $A24344 – $A30,038
Senior Research Scientist (SRS) $A31,092 – $A35,806

Conditions:
Conditions of service include superannuation, long service leave, four weeks annual leave and removal expenses to Canberra. Permanent appointment is available to persons who are Australian citizens. A term engagement will be considered for persons not meeting this criterion.

Canberra, the national capital, is located approximately 280 km southwest of Sydney and has excellent educational, recreational and sporting facilities.

Applications together with full personal and professional details and the names of at least three referees should be sent to:
The Director
Bureau of Mineral Resources
GPO Box 378
Canberra ACT 2601
AUSTRALIA

Applications close 16 March 1984.

(W780)A

AUSTRALIA

UNIVERSITÄT FREIBURG
anticipates the appointment of a
FULL PROFESSOR
at the Lehrstuhl für Makromolekulare Chemie.

Applicant should have interest in synthetic polymer or biopolymer esearch. The candidate should have a strong commitment to graduate nd undergraduate teaching. Scientific cooperation within DFG joint esearch groups, especially "Funktion durch Organisation in makro-nolekularen Systemen", is offered.

Applicants should supply curriculum vitae and lists of ublications and teaching experiences. They should be sent to he Dekan der Fakultät Chemie – Pharmazie, Universität reiburg, Rheinstraße 10, D-7800 Freiburg, West-Germany, by March 15, 1984.

TRANSGENE

As a consequence of continued growth and expansion, and of a recent move into new, larger premises, TRANSGENE, a leading genetic engineering company based in STRASBOURG, FRANCE, has immediate openings in the following positions.

— SENIOR MOLECULAR BIOLOGIST

with extensive experience in eukaryotic cell vectors and in the expression of foreign proteins in cultured cells.

— BACTERIOLOGIST

with research experience in the physiology and genetic manipulation of microorganisms of industrial importance (the streptococci, lactobacilli, streptomyces . . .).

— MOLECULAR BIOLOGIST

with 2-3 years practical experience of cDNA cloning techniques.

— PROTEIN CHEMIST

with practical experience in the synthesis of peptides.

TRANSGENE is an independent recombinant DNA research and development company, backed by a group of major French industrial and financial organizations.

Interested candidates are invited to submit, in confidence, a full curriculum vitae, a list of publications, and the names and addresses of three referees to:

Dr. J. P. LECOCQ
Scientific Director
11 rue de Molsheim
67000 STRASBOURG
FRANCE
Tel: (88) 22.24.90.

(W756)A

UNIVERSITY OF GRONINGEN
Kapteyn Astronomical Institute

RESEARCH ASTRONOMERS

Two positions are available, each for 2 years. Commencing date flexible, preferably September 1984. The institute's research interests lie in extragalactic and interstellar research, both observational and theoretical, and advanced facilities for image processing and model calculations are available. Observing possibilities exist with first rank instruments both nationally and abroad. The infrared sky survey data obtained with the IRAS satellite are available for comparative work.

Candidates must be in the possession of a PhD or equivalent degree in order to begin these appointments. One of the positions will be given to a candidate with a demonstrated interest in observational astronomy and will involve half of the 2-years at the UK-Dutch La Palma Observatory as a resident astronomer.

Applicants are requested to send a curriculum vitae, list of publications and a summary of current research interests, and to arrange to have 3 letters of reference sent directly to: Prof. R. J. Allen, chairman Astronomy Department, Postbus 800, 9700 AV Groningen, The Netherlands, phone 50116695, telex 53572 stars nl. Closing date: 31 March 1984. (W770)A

IMMUNOLOGY R & D

IMREG, INC., a publicly held biotechnology company engaged in development of immunoregulators for human application is expanding its scientific staff, and has openings for scientists with the following qualifications:

(1) PhD level scientists with postdoctoral training and experience in cellular immunology, peptide biochemistry, and recombinant DNA technology.

(2) Research Associates with M.S. degrees or B.S. degrees in all of the above areas.

(3) M.D. clinical scientist with interest and experience in laboratory or clinical immunology to assist in design and coordination of clinical trials of the Company's immunomodulators.

These are intellectually challenging positions at the advancing edge of the rapidly developing area of human lymphokines.

We offer competitive salaries appropriately scaled for training, experience and record fo productivity in research, and an attractive fringe benefit package including an incentive stock option plan. We are located in an attractive, fully-equipped setting in one of America's most interesting cities. The Company maintains linkages to the local and national academic immunologic community. Send curriculum vitae and names of three references in confidence to John L. Carlton, Vice-President of Operations and Finance, IMREG, INC., P.O. Box 56643, New Orleans, 70156. (NW308)A

UWIST

University of Wales

APPLIED BIOLOGY LECTURERS

Microbiology and Molecular Biology Position

RESEARCH ASSOCIATE

supported by a SERC Biotechnology Directorate Grant to characterise the dehalogenase transposons of Pseudomonas putida. Applicants must have a wide experience in molecular biology techniques.

Salary: Within Range 1A Research and Analogous Staff £7,190 – £11,615 per annum.

Requests (quoting Ref. B31) for details and application form to Staffing Office, UWIST, PO Box 68, Cardiff CF1 3XA.

Further information can be obtained from Professor J. H. Slater, on Cardiff (0222) 34130.

Closing Date: 9 March 1984.

(1269)A

UNIVERSITY OF STRATHCLYDE
Department of Bioscience and Biotechnology
(Applied Microbiology Division)
POSTDOCTORAL RESEARCH FELLOW

Applications are invited for a Post-doctoral Research Fellowship (tenable for three years) to work with Dr D R Berry and Dr J Johnston on the genetic manipulation of yeast strains. Candidates should have experience of nucleic acid biochemistry or molecular biology.

Salary on Range IA (£7,190 – £11,615 pa) of the national salary scale for Research Staff. USS benefit.

Applications (two copies) with curriculum vitae and the names and addresses of three referees (quote ref: R5/84) should be sent to Dr R S Henderson, Department of Bioscience and Biotechnology, University of Strathclyde, 204 George Street, Glasgow G1 1XW by 23 March 1984. (1257)A

CONNECTIVE TISSUE RESEARCH
FACULTY OF DENTISTRY
THE UNIVERSITY OF ALBERTA

Applications are invited for a full-time position as a Research Scholar for fundamental studies on connective tissue involving periodontal disease and wound healing. Present research includes studies on the structures and functions of collagens and proteoglycans and mechanisms of connective tissue degradation. Expansion of these studies or sound independent research in another area by Research Scholars with the requisite experience will be considered. Facilities include automatic amino acid sequencing, tissue culture and electron microscopy with associated clinical areas.

These positions are dependent upon successful application for competitive awards by an external granting agency. Appointment will be on a long-term basis and will enjoy the previleges of the University academic rank at which the appointment is made (Assistant Professor, Associate Professor or Professor level presently $29,720 – $41,820; $37,420 – $53,658 and from $48,010). University of Alberta is an equal opportunity employer.

Interested applicants should forward their curriculum vitae, outlines of their research interests and names of three referees to Dr. J. A. hargreaves, Director of Graduate Studies and Research, Faculty of Dentistry, The University of Alberta, Edmonton, Alberta T6G 2N8.

The closing date for application is May 1, 1984. (NW314)A

University College of Swansea

Senior Research Assistant

plications are invited for an **RC-funded Senior Research sistant in the Department of ysics,** to join an existing High ltage Group based at the above llege and UWIST at Cardiff. plicants should have a good ial degree in Physics, Electrical gineering or a related subject, gether with some relevant search experience. The research, hich is closely integrated with that a number of European groups, l involve a study of the growth of ace charge in transient electrical charges in gases at voltages up 250 kV. The experimental work l be carried out mainly in the high ltage laboratory at Swansea ng an existing experimental angement for which micro-ocessor-based multi-channel ta acquisition systems are being veloped.

e appointment, which will be for o years from the soonest date at can be arranged, will be at a mmencing salary of £8,080 per num plus USS/USDPS benefits.

ormal enquiries may be made Professor J. Dutton, partment of Physics at vansea or Professor R. T. ters, Department of Physics, ctronics and Electrical gineering, UWIST, Cardiff, t further particulars and plication forms (2 copies) st be obtained from the rsonnel Office, University llege of Swansea, Singleton rk, Swansea SA2 8PP, to hich office they should be urned by Thursday, March 1, 4.

Public Service Commission of Canada / Commission de la Fonction publique du Canada

Research Scientist, Marine Organic Geochemistry

Fisheries and Oceans
Champlain Centre for Marine Science and Surveys
Quebec City, Quebec

We require a senior scientist to be responsible for conducting a research program on behaviour pathways and fluxes of organic substances, particularly contaminants in the coastal marine environment. We will rely on you to carry on research in physical, chemical, and biological oceanography on processes in the Estuary and Gulf of St. Lawrence and in coastal waters in Northern Quebec. These activities will be transferred to a new research institute near Mont-Joli sometime in 1986-87.

You require a doctorate degree in oceanography with specialization in organic geochemistry from a recognized university, or a lesser degree with research experience and scientific productivity equivalent to a doctorate. In addition to extensive field and successful research experience, it is essential that you have published original articles. Willingness to work in the field in all seasons for long periods is mandatory. Knowledge of English and French is essential. Please note that in some cases language training may be offered.

We offer a salary ranging from $26,834 to $49,913 commensurate with your qualifications and experience.

Send your application and/or résumé and list of publications, quoting reference number 84-NCRSO-DFO-RES-5, to:
Joan Girling (613) 593-5331
Public Service Commission of Canada
Ottawa, Ontario

Closing date: 30 March 1984

Tout renseignement est disponible en français en s'adressant à la personne susmentionnée.

UNIVERSITY OF EDINBURGH

DEPARTMENT OF BOTANY

CTURER IN MYCOLOGY

lications are invited for the ve post available from 1st ober, 1984.

andidates should hold a PhD ee, or the equivalent, and have at three years postdoctoral rience in any aspect of fungal arch although candidates with an est in experimental aspects are y to be preferred. The successful idate will be expected to develop her personal research ramme and assist in the training oth general and more specialised cts of mycology.

lary on the academic scale for urers (£7,190 — £14,125) rding to qualifications and rience.

urther particulars may be ained from the Secretary, versity of Edinburgh, Old lege, Edinburgh, quoting ence number 1105. Closing date pplications 1st May, 1984.

(1289)A

MOLECULAR BIOLOGISTS

The Department of Biology of Memphis State University invites applications for a tenure track faculty position in the area of molecular biology at the level of assistant or associate professor. The applicant must have postdoctoral experience with demonstrated excellence in molecular biology including recombinant DNA methodology. This position includes ample space and funding for research. It is expected that the successful candidate will develop a research program that will qualify for extra mural funding. The individual will also be expected to participate in appropriate departmental teaching.

Interested individuals should submit a résumé, a statement of research plans, reprints of publications and have 3 letters of recommendation to: Dr Lewis B Coons, Chairman, Search Committee, Department of Biology, Memphis State University, Memphis TN 38152. The Memphis State University is an equal opportunity university. The closing date is April 30, 1984. (NW328)A

NATURE CONSERVANCY COUNCIL

DIRECTOR SCOTLAND

£19,243 — £23,159

Applications are invited for the post of Director Scotland which will be vacant in January 1985 on the retirement of the present Director Dr. J. Morton Boyd, BSC PhD DSc FRSE.

The person appointed will be responsible for NCC's activities in Scotland including a staff of 115 and 61 National Nature Reserves and over 800 Sites of Special Scientific Interest and will work closely with the Chairman of Council's Advisory Committee for Scotland. As a member of the Board of Directors the Director contributes to the formulation and implementation of Council's policies and to the wider management of NCC throughout Great Britain.

Candidates must be capable of working at the highest levels with Central and Local Government and Agencies, with land managers and users, and with scientific, professional and voluntary bodies.

A proven capacity for leadership and management is required as is an appropriate background of experiece. The post provides outstanding opportunities for developing nature conservation.

The post is graded at Deputy Chief Scientific Officer and is based in Edinburgh.

Interviews will be held in London (19/20 Belgrave Square) during May 1984.

For application forms and further details contact Mrs J. Whitting, Nature Conservancy Council, Godwin House, George Street, Huntingdon, Cambs. Tel: Huntingdon 56191 ext 278.

Closing date for receipt of completed application forms is 30 March 1984.

(1282)A

esa

EUROPEAN SPACE AGENCY

The European Space Agency seeks for its European Space Research and Technology Centre, Noordwijk, an

ASTRONOMER MILLIMETER AND SUB-MILLIMETER WAVE ASTRONOMY

Applications are invited from astronomers with experience in millimetre wave heterodyne observations of molecular clouds. Applicants should have demonstrated research ability and a sound knowledge of heterodyne receivers. The post requires an ability to lead a small group in collaborative research with other European astronomers, to direct the development of advanced instrumentation for submillimetre wave astronomy from space, and to lead a study group examining the feasibility of an 8 metre diameter space telescope for submillimetre wave astronomy.

An excellent knowledge of English or French is essential with a working knowledge of the other language.

We offer international working conditions, expatriation and family allowances, good social security and pension.

Interested candidates are requested to apply, sending a detailed curriculum vitae to the Head of Personnel, ESTEC, P.O. Box 299, 2200 AG Noordwijk, the Netherlands.

(W764)A

PLANT EVOLUTIONARY BIOLOGIST — FACULTY POSITION

The Department of Plant Biology, University of Illinois at Urbana-Champaign, invites applications for a tenure-track position at the assistant professor level for appointment in August 1984. Applicants must have a PhD and have research experience in evolutionary studies of higher plants and in plant systematics utilizing approaches of molecular biology. The appointee will be expected to conduct research in evolutionary relationships of plants and contribute to both graduate and undergraduate teaching programs. It is anticipated that this person will complement and interact with present faculty in evolutionary and systematic biology. Salary is open, depending on the applicant's qualifications.

Applications must include a curriculum vitae, a summary of research and teaching interests and at least three letters of reference which are to be sent to: Dr. David S. Seigler, Search Committee Chairman, Department of Plant Biology, University of Illinois, 505 South Goodwin Street, Urbana, Illinois 61801; telephone (217) 333-7577 or 333-3261. In order to ensure full consideration, applications must be received by March 19, 1984. The University of Illinois is an Affirmative Action/Equal Opportunity Employer.

(NW334)A

McGill University
DEPARTMENT OF PLANT SCIENCE

Applications are invited for two Assistant Professor positions

1. **Plant Pathologist/Molecular Biologist.** Teach undergraduate plant physiology and an additional botany or plant pathology course, plus graduate teaching and research in area of expertise. PhD, background in molecular biology of plant pathogens/host pathogen relations required.
2. **Plant Pathologist** with strong background in quantitative biology. Teach undergraduate crop diseases and nematology; develop graduate course and research in epidemiology and crop disease modelling. PhD required.

Send application, C.V., and three references to Dr J.F. Peterson for position 1, and to Dr H.R. Klinck for position 2 at Search Committee, Department of Plant Science, Macdonald College, 21,111 Lakeshore Road, Ste. Anne de Bellevue, Quebec, Canada H9X 1CO.

Final selection will not be made before April 15. Starting date, 1 September 1984. Starting salary $29,500. All qualified applicants are encouraged to apply, but in accordance with Canadian Immigration regulations, this advertisement is directed to Canadian citizens and permanent residents of Canada. (NW323)A

M R C CLINICAL RESEARCH CENTRE
(NORTHWICK PARK HOSPITAL)
WATFORD ROAD, HARROW
MIDDLESEX HA1 3UJ

PAEDIATRIC RESEARCH GROUP — MASS SPECTROSCOPIST

Applications are invited from graduates for this scientific post to participate with biochemists and clinicians in a research programme in paediatric metabolism. Areas of particular interest are inborn errors of metabolism, and metabolic homeostasis and its control. The post holder will be responsible for the co-ordination and conduct of the mass spectrometric work of the group (Head, Dr. T.E. Stacey) which will include use of stable isotopes.

Previous practical experience in mass spectrometry is essential, preferably in organic chemistry or biochemistry. The appointment is for 3 years in the first instance. Salary will be in the range £8,376 – £11,426 p.a. inclusive, depending on qualifications and experience.

Candidates who wish to apply should send a curriculum vitae and the names of two professional referees to Jean Cottam, Personnel Section, quoting ref. no. 123/1/3912. Closing date for application 16th March 1984. (1283)A

THE UNIVERSITY OF LEEDS

DEPARTMENT OF EARTH SCIENCES

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post for work on radiogenic isotope geology. The appointment is available immediately for a fixed term of up to 18 months. Applicants should have experience in radiogenic isotope geology and preferably interests in igneous geochemistry. The successful candidate will be expected to initiate research projects, collaborate on current research and assist in the training of research students in the isotope geology laboratories.

Salary within the range £7190 £10250 on the IA Range for Resea and Analogous Staff (£7190 £11615) according to age, qualifi tions and experience.

Informal enquiries may be made Professor Briden, Department Earth Sciences, The University Leeds.

Application forms and furt particulars may be obtained from Registrar, The University, Le LS2 9JT quoting reference num 49/27/D. Closing date for appli tions is 31 March 1984.

Applicants from overseas m apply by telegram or telex (556 UNILDS G) in the first instance. (1264)A

UNIVERSITY OF CALIFORNIA
SCHOOL OF MEDICINE

DEPARTMENT OF MICROBIOLOGY AND IMMUNOLOGY

HEAD, DIVISION OF IMMUNOLOGY

The School of Medicine of the University of California, San Francisco is seeking a Head for the Division of Immunology within the Department of Microbiology and Immunology. The Head will occupy a tenured faculty position with joint appointments in the Department of Microbiology and Immunology, and the Cancer Research Institute. Qualified individuals will have training and experience in molecular biology and immunogenetics, and a demonstrated capacity for independent, creative activity of distinction. In addition to responsibilities in research and teaching immunology to medical students, other health sciences students and graduate students, the Head will lead a graduate degree program in immunology utilizing the resources for immunology and related disciplines on the University of California, San Francisco campus.

Applications with curricula vitae should be sent to Dr. John D. Stobo, HSW-473, University of California, San Francisco, California 94143. An Affirmative Action/Equal Opportunity Employer. (NW311)A

A nmitment to applying such hods toward a solution of virus ease development and virus-host eraction, and etiology and lemiology of plant virus diseases. teaching responsibilities will ude participation in a team taught dergraduate Comparative ology course and major involve- t in a graduate course in Plant ology.

pplicants should submit a riculum vitae, transcripts, lications and a brief description esearch goals, and arrange for e letters of reference to be sent to: Morris, Chair, Search Commit- Department of Plant Pathology, versity of California, Berkeley 94720, by April 30, 1984.

he University of California is an al Opportunity, Affirmative ion Employer. (NW331)A

IVERSITY OF LEICESTER

PARTMENT OF BIOCHEMISTRY

ESEARCH ASSISTANT 1B

ent graduates from relevant fields invited to apply for the above t, to work on applications of in o mutagenesis to cloned genes olved in oncogenesis.

he post is funded by the Cancer earch Campaign and will be for years, starting as soon as sible. The salary will be on the 1B e, starting at £6,310.

pplications with curriculum vitae the names of two referees should ent to Dr. I.C. Eperon, University Leicester, Department of chemistry, Adrian Building, versity Road, Leicester LE1 7RH 0533 551234, ext. 391) from m further information can be ained. (1253)A

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF CHEMISTRY
(SERC Daresbury)

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited from chemists and physicists for the above post tenable for up to two and a half years. Synchrotron radiation and fast particles will be used to study primary processes resulting from the absorption of high energy radiation; the dependence of luminescence decays on photon energy and magnetic field will be measured. The main experiments will be carried out at the SERC's Daresbury Laboratory; the research assistant could be based in Sheffield or Daresbury. Research experience with synchrotron radiation, vacuum ultraviolet, single-photon counting or luminescence and an interest in computing would be useful.

Salary £7190 to £7630 a year on Range IA: possibility of higher salary at reduced tenure.

Details from Dr. B. Brocklehurst, Department of Chemistry, The University, Sheffield S10 2TN to whom applications, naming two referees, should be sent as soon as possible. Quote ref: R40/G. (1284)A

GODDARD INSTITUTE FOR SPACE STUDIES POSTDOCTORAL POSITION IN PHYSICS AND ASTROPHYSICS

Two postdoctoral positions will be available at the Goddard Institute for Space Studies in the summer of 1984. One is for a radio or infrared astronomer to work in the general area of molecular clouds and galactic structure. The other is for a laboratory astrophysicist to work on the millimeter-wave and far IR spectroscopy of molecular ions and radicals that might be detected in space.

Candidates should send their curriculum vitae to Dr Patrick Thaddeus, and should arrange to have three letters of recommendation sent to Goddard Institute for Space Studies, New York, New York 10025, at the same address. (NW325)A

CSIRO
TAXONOMIST
$A24,344 — $A35,806
Division of Entomology
Canberra Act Australia

Field: Taxonomy of Mites (Acari).

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Entomology is a member of the Institute of Biological Resources.

General: The Division carries out basic and applied research on many entomological problems of economic importance, and is the main centre in Australia for research on insects and related arthropods. A wide range of ecological studies is in progress and there are numerous other projects covering diverse fields of entomology. The professional staff numbers over 120, including 8 full-time and several part-time taxonomists, who are responsible for research on the Australian insect fauna and the curation of the Australian National Insect Collection (ANIC). The Division has excellent research and library facilities.

Duties: To undertake taxonomic research on mites and be responsible for the development and curation of the ANIC collection of Australian Acari. Substantial holdings of some families are already on hand. Opportunities will be available to participate in faunal survey and other relevant field work. Some identification responsibilities are involved.

Qualifications: A PhD degree or equivalent qualifications, with considerable research experience and a special interest in the taxonomy of Acari.

Tenure: Indefinite with Australian Government superannuation benefits available.

Note: Applicants with an exceptional level of research achievement may be considered for appointment at a higher salary.

Applications: Stating full personal and professional details, the names of at least two referees and quoting reference No A2188, should be directed to:

The Chief,
CSIRO Division of Entomology,
GPO Box 1700,
CANBERRA ACT 2601.
AUSTRALIA.
By March 23, 1984. (W765)A

UNIVERSITY OF READING

DEPARTMENT OF AGRICULTURE & HORTICULTURE

RESEARCH FELLOW

required immediately in the Sub-Department of Horticulture to work with Dr P Hadley on the action of chemical plant growth regulators on the growth and physiology of crop plants. The post is for a fixed term of three years.

Candidates should hold a PhD degree and have research experience in plant physiology and/or plant biochemistry. Interests in carbon assimilation and carbon economy would be an advantage. Starting salary £7,190 pa. Apply, quoting Ref R7A, for application form to Personnel Office, University of Reading, Whiteknights, Reading RG6 2AH. (1271)A

Athrofa Gogledd Ddwyrain Cymru
The North East Wales Institute
of higher education

DEESIDE, CLWYD — RESEARCH DIVISION

TECHNICIAN BIOTECHNOLOGY

Scale 1 — 3 (£2,976 — £6,135)

Applications are invited for a Technician to assist an industrial/SERC supported team working on immunoassays for novel purposes. The post is initially available for 23 months. Applicants, should have biological and biochemical experience.

Further details and application form available from the Registrar, The North East Wales Institute, Deeside, Clwyd. Tel: Deeside 817531 ext 254. Closing date for receipt of applications 9th March 1984. (1278)A

Electro neuropharmacologist

PhD degree neurophysiology

An important pharmaceutical Research Centre in the West Paris suburbs is seeking a Neurophysiologist to direct its Electrophysiology Laboratory for the investigation of the mechanisms of action of psychotropic and neurotropic agents.

Candidates in their early thirties should have a PhD degree or equivalent in Neurophysiology with knowledge of neuropharmacology, biological statistics and the use of microcomputers. Adequete spoken French is a requirement.

Please send hand-written letter, C.V., photo, salary requirements with ref. 2822/N on the enveloppe to **MEDIA P.A.** - 9, boulevard des Italiens - 75002 PARIS. (W766)A

MEDIA PA

Max-Planck-Institut für Biologie, Tübingen
POST-DOCTORAL POSITION

Position for research in Molecular Biology/Immunology of Parasitic Protozoa. Applications are invited from scientists interested in studying the interaction of parasite surface receptors with host cells, and the control of their expression during parasite differentiation. Preference will be given to applicants with a background in molecular biology/immunology. Experience of parasitic protozoa is not necessary. Appointments from April or later, salary according to stipend regulations (DM 2,200-2,400/month, tax-free).

Applications with curriculum vitae, publications list and names of referees should be sent to: Prof. Dr. P. Overath, Max-Planck-Institut für Biologie, Correnssstrasse 38, 74 Tübingen, W. Germany. (W768)A

Pathologist

In the development of any new drug, evaluating its safety for man is an essential element. As part of a continued expansion of such activity Beecham Pharmaceuticals has acquired a purpose built site at Stock, near Chelmsford, Essex.

We are now seeking to recruit a laboratory animal pathologist to carry out the histopathological assessment of tissues from animals used in safety studies.

Applicants should have a degree in veterinary science or a good honours degree (at least 2.1 standard) in a related subject. Relevant practical experience would be a distinct advantage.

We can offer an attractive salary, pleasant working conditions together with the usual fringe benefits of a large and successful company.

For an application form, please write to the Personnel Department, Beecham Pharmaceuticals Research Division, Honeypot Lane, Stock, Essex quoting ref. 3/84.

(1292)A

Beecham Pharmaceuticals

RESEARCH Assistant, MSc or PhD in biochemistry. Experience and publications in membrane immunochemistry of human leukemia cells. Salary at technical level, commensurate with experience. Hospital appointment in Toronto, renewable annually, to begin July 1984. Curriculum vitae and references to Dr M Baker, 399 Bathurst Street, Toronto, Ontario, M5T 2S8 Canada. (NW312)A

UNIVERSITY OF UTAH
DEPARTMENT OF BIOENGINEERING

Applications from candidates with an earned doctorate are invited for one/two tenure track faculty positions, assistant to full professor level. The appointee(s) will teach courses in bioengineering and will be expected to conduct an outstanding independent program of research. Joint appointments with other departments possible.

Send curriculum vitae and three recent publications to: Prof Richard A Normann, Department of Bioengineering, University of Utah, Salt Lake City, Utah, 84112. Application deadline April 15, 1984. An affirmative action/equal opportunity employer. (NW294)A

IMMUNOLOGY FACULTY POSITION

Tenure Track, at either Assistant/Associate or Full Professor, Department of Microbiology, Southwestern Medical School, Dallas.

Areas of particular interest include molecular genetics, cellular immunology and cell cloning. Rank and salary open. Current members of faculty are: Drs Capra, Forman, Kettman, Lipsky, Sullivan, Tucker, Uhr, Vitetta, and Wasserman.

Applicants should submit curriculum vitae, description of research interests and names of 4 references to Dr J W Uhr, Department of Microbiology, Southwestern Medical School, 5323 Harry Hines Blvd., Dallas, Texas 75235.

The University of Texas Health Science Center is an equal opportunity/affirmative action employer. (NW326)A

HERIOT-WATT UNIVERSITY
DEPARTMENT OF CHEMISTRY
LECTURESHIP

Applications are invited for Lectureship in Inorganic/Analytic Chemistry from 1 October 1984. It essential that the candidate shou have a high research potential a strong interest in teaching. T Department of Chemistry is locat on the Riccarton Campus of t University. An appointment will made at an appropriate point on t Lecturer salary scale £7190 — £141 — plus USS benefits.

Applications forms and furth particulars may be obtained from t Staff Officer, Chambers Stree Edinburgh EH1 1HX quoting re 12/84 to whom completed applic tion forms should be returned by March 1984. (1258)A

CHAIRMAN
DEPARTMENT OF ANATOMY

Applications are invited for t position of Professor and Chairma Department of Anatomy, Schools Medicine and Dentistry, Universi of Alabama in Birmingham. We a seeking candidates with research a teaching experience, leadersh qualities, and administrative skil This department has teachi responsibilities for graduate stude in anatomy, medical, dental a other students.

Please submit applications anc curriculum vitae to: Antonietta Hyche, Administrative Offic University of Alabama School Medicine, Dean's Office — M 306, Birmingham, Alabama 352 An Equal Opportunity/Affirmat Action Employer. (NW263)A

CENTRAL PUBLIC HEALT LABORATORY
VIROLOGIST

A graduate with 1st or 2nd cl honours degree and with 2 or m years experience in virology required to assist with a proj concerned with the transmission hepatitis A virus to man by shellf and procedures of inactivation.

The project is funded by DHSS a period of 2 years.

Salary on Whitley Coun scientific scale £6,759 — £8,349 p £623 London Weighting. The sc quoted is dependant upon experie relevant to the Terms and Conditic of service.

Application forms may obtained from the Person Department, Central Public Hea Laboratory, Colindale Avenu London NW9 5HT. (1270)A

Nominations invited for the

1984 BROOKDALE AWARDS FOR DISTINGUISHED CONTRIBUTIONS TO GERONTOLOGY

The Gerontological Society of America announces three Brookdale Awards for Distinguished Contributions to Gerontology:

I. To a **citizen of the United States** for contributions to Gerontology through **research in the Social or Behavioral Sciences**

II. To a **citizen of the United States** for contributions to Gerontology through **leadership in Biology or Clinical Medicine**

III. To a **citizen of another nation** for contributions to Gerontology through **research and/or leadership**

Each awardee will receive a $25,000 cash prize and will be honored at a special ceremony during the 1984 Annual Scientific Meeting of The Gerontological Society of America in San Antonio, Texas.

Nominations

Nominations can be made by any individual or organization and should be submitted in the form of a letter setting out in detail the significance of the individual's contributions. A curriculum vitae and two other letters of endorsement must accompany the nomination. Eight copies of these materials should be sent to The Gerontological Society.

Nominees must be gerontologists who have been recognized both nationally and internationally for their distinguished contributions to the field.

Deadline for Nominations

Nominations should be addressed to the

Brookdale Awards
% The Gerontological Society of America
1411 K Street N.W., Suite 300
Washington, D.C. 20005

and must be received no later than May 2, 1983.

SEMINARS and SYMPOSIA

INSTITUTE OF BASIC MEDICAL SCIENCES
ROYAL COLLEGE OF SURGEONS OF ENGLAND
First Announcement of Three-Day Interdisciplinary Symposium
"INTERACTIONS OF CELLS WITH NATURAL AND FOREIGN SURFACES"
28TH, 29TH and 30TH NOVEMBER, 1984
Co-Organisers:
Professors N. Crawford and D. E. M. Taylor
— at the
ROYAL COLLEGE OF SURGEONS OF ENGLAND
LINCOLN'S INN FIELDS, LONDON WC2A 3PN

This Symposium will provide an overview of an important and rapidly developing interdisciplinary field and is intended to improve understanding and generate dialogue between life scientists, clinicians and materials scientists. In particular it will provide a link between the more basic biology of cell interactions with surfaces and its application and relevance to the use of biomaterials in clinical practice.

The Symposium will include eight sessions of invited papers by experts in their fields, three oral communication sessions for free papers on basic and applied aspects and a number of poster sessions. Topics to be covered will include:

MEMBRANE STRUCTURE, ORGANISATION AND ELECTROKINETIC PROPERTIES
BIOTOLERANCE AND HAEMOCOMPATIBILITY
ASSESSMENT OF BIOCOMPATIBILITY OF MATERIALS
ANTITHROMBOTIC SURFACES: DESIRABLE PROPERTIES
CELL BIOLOGY OF WOUND HEALING AND WOUND MANAGEMENT
ORTHOPAEDIC IMPLANTS, BEARING SURFACES, FIXATIVES
CARDIOVASCULAR IMPLANTS AND EXTRACORPOREAL CIRCUITRY
TUMOUR METASTATIC SPREAD, CARCINOGENICITY OF MATERIALS
DENTAL MATERIALS, FILLERS, CEMENTS, CELL/POLYMER INTERFACES

For further information and registration forms etc, write to:
I.B.M.S. Symposium 1984
Royal College of Surgeons of England,
Lincoln's Inn Fields, London, WC2A 3PN.

ALCOHOL

The 15th international symposium on food subjects, organised by the National College of Food Technology, University of Reading, will be on Alcoholic Beverages. The symposium will be held at the new centre of food studies, University of Reading, 27-29 March 1984.

Details from Dr G. G. Birch, National College of Food Technology, Department of Food Technology, Food Studies Building, University of Reading, Whiteknights Reading RG6 2AP. (1279)M

ANNOUNCEMENTS

THE ROYAL SOCIETY
GUEST RESEARCH FELLOWS

The Council of the Royal Society invites applications for the support of Guest Research Fellows. The object of this scheme, established in 1980, is to assist outstanding leaders in research in the United Kingdom to invite as guests scientists of proven ability, normally resident overseas, to come and work with them for periods of at least four months and not exceeding two years. The aim is to provide for research needs which can best be met by such international collaboration. Emphasis in selection will be on the abilities and field of research of applicants and on special contributions to the applicant's research which would be provided by the visitor and are not available in the United Kingdom; applicants must be working in the United Kingdom.

Applications should be made on forms to be obtained from the Executive Secretary (GRF/UMAM), The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG, and returned by 30 April 1984. (1261)G

ASSISTANTSHIPS

THE UNIVERSITY OF SHEFFIELD
WOLFSON INSTITUTE FOR BIOTECHNOLOGY
RESEARCH POSTS IN PLANT CELL BIOTECHNOLOGY
POST-DOCTORAL RESEARCH ASSISTANTSHIPS

Two Postdoctoral Research Assistants are required to work on natural product synethesis in plant cell culture in the food and flavour area. The projects are supported by grants from industry and are available for a period of one year in the first instance, commencing as soon as possible. Applicants should have a first degree in Microbiology, Microbial Biochemistry or Natural Product Chemistry. Salary in the range of £7,190 — £8,080 a year on Range IA for Research and Analogous Staff.

Further details from Professor M.W. Fowler or Dr. A.H. Scragg, Wolfson Institute of Biotechnology, the University, Sheffield S10 2TN (0742 — 78555 Extn. 4245) to whom applications, including the names of three references, should be sent as soon as possible. Quote ref: R38/G. (1285)P

CONFERENCES and COURSES

1984/85

INTER-UNIVERSITY MSc COURSE ON THE PHYSICS AND TECHNOLOGY OF AMORPHOUS MATERIALS

Universities of Dundee
Edinburgh — Glasgow

The one year advanced course, in this rapidly developing field, is offered jointly by the above named Universities. Course work will be given at the University of Dundee. For the project work, students will join a research group at one of the participating institutions.

Applications are invited from students with an honours degree (or its equivalent) in either Physics, Electrical Engineering, Chemistry, or a Materials Science. The course has been approved by the Science Research Council and Advanced Course Studentships are available for suitably qualified applicants.

Further information may be obtained from: Professor W E Spear, FRS, Carnegie Laboratory of Physics, The University, Dundee DD1 4HN. (1290)C

CHELSEA COLLEGE
University of London
STUDY HISTORY AND PHILOSOPHY OF SCIENCE AT CHELSEA

One year MSc courses begin Octob 1984. Facilities for MPhil and Ph by research. Applicants must posse a first degree in one of the natur sciences or mathematics. All cours approved for DES grand award Early application is advised since t closing date for applying for a DE award is 1 May.

Send for details to Dr M L Redhead, Department of History a Philosophy of Science, Chels College, University of Londo Manresa Road, London SW3 6L Tel. 01-351 2488. (1250)C

continued on page 16

FELLOWSHIPS

A POSTDOCTORAL Fellowship available in protein crystallograp related to active sites and regulato mechanisms, including enzym modified at the DNA level by reco binant techniques. Applicants fro the area of small molecule cryst lography will also be considere Applicants may write to Pr William N Lipscomb, Gib Chemical Laboratory, Harvard U versity, Cambridge, MA 0213 USA. Harvard University is Affirmative Action/Equal Opp tunity Employer. (NW301)E

UNIVERSITY OF ABERDEE
DEPARTMENT OF CHEMISTRY
POSTDOCTORAL RESEARCH FELLOWSHI

Applications are invited to join research team whose objective is establish a scientific basis for physical and chemical immobili tion of certain radioactive wastes cement-based systems. In order compliment the skills of ot members of the team, applica should preferably be familiary w radiochemical methods a procedures.

The post is available immediate An initial appointment will be m until 31 March 1985 but it envisaged that the work, which supported by the Department Environment and the Commissio the European Communities, will continued for a further period.

Salary, depending on qualifi tions and experience is in the ra 1A scale for Research and Analog Staff (£7,190 — £11,615) with app priate placing.

Further particulars and appli tion forms from The Secretary, University, Aberdeen, with wh applications (2 copies) should lodged by 16 March 1984.

Informal enquiries may be mad Professor F P Glasser (T 0224-40241 Ext: 5640). (1254)

UNIVERSITY OF CAPE TOWN

Postdoctoral Research Fellowships 1985

The University of Cape Town annually invites applications for Post-doctoral Research Fellowships to be held at the University.

The Fellowships are tenable for a maximum of twelve months and the stipend attached to the current Fellowships is R1 500 p.m. (R18 000 p.a.). Successful candidates from abroad will receive an additional Travel grant up to a maximum of R2 000. (Some increase in these values to keep pace with inflation is possible for 1985). There is no restriction to any particular field of research.

Preference will be given to recently qualified research workers but reduced awards suitable for a visit of about three months have sometimes been made to tenured staff members of universities. Preference is also given to applicants whose research interests and facilities needs mesh well with those of the appropriate host department.

Applications must include full details of the applicant's envisaged research programme in addition to a full curriculum vitae and the names of two referees whom the University may consult. The policy of the University is not to discriminate in the appointment of staff on the grounds of sex, religion, race, colour or national origin. The dates upon which the successful candidates will be expected to take up their duties are flexible and can be arranged to suit the special circumstances of each candidate.

Applications should be addressed to the Head, Research Administration, University of Cape Town, Private Bag, Rondebosch 7700, South Africa, so as to reach him by 10 June 1984. The first round of award letters will be despatched by the end of August 1984.

(W773)E

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL FELLOWSHIP

Applications are invited for a Post-doctoral Fellowship for research in the Biochemistry of vision. The appointment will be for two years. Preference will be given to candidates with experience of protein chemistry and sequence analysis.

Salary on Scale 1A (£7,190 — £11,615) for Research and Analogous Staff.

Applications should be sent to Professor M Akhtar FRS, Department of Biochemistry, University of Southampton, Southampton SO9 3TU.

Please quote Ref. No 1266 as soon as possible. (1266)E

UNIVERSITY COLLEGE DUBLIN
Department of Geology

The Department invites applications from suitably qualified individuals for Department of Education Postdoctoral Fellowships 1984-85. These are administered by the Department of Education and are tenable for a period of two years with a possible extension for a third year. Applicants should hold the degree of PhD or have equivalent research experience at the time of taking up the award. They should be under 30 and preferably under 28 years of age on March 31, 1984. Appointment will be effective from a date not earlier than October 1, 1984. Salary, dependent upon qualifications and experience, will be in the range IR£6,961 — IR£7,876 per annum.

The Department of Geology is particularly interested in applications from persons with interests in isotope geochemistry, fluid inclusion studies and mineralisation, micropalaeontology or Irish Caledonian geology, but applicants with other research interests will also be considered. Interested persons are requested to contact Prof. M. J. Kennedy, Department of Geology, University College, Belfield, Dublin 4 for further particulars of the facilities and research opportunities in the Geology Department.

Applications should be made directly to the Secretary, Department of Education, (Headquarters Section 3), Marlborough Street, Dublin 1, from whom application forms and full particulars of the fellowship scheme can be obtained. The deadline for receipt of applications by the Department of Education is March 31, 1984. (1260)E

POSTDOCTORAL FELLOWSHIPS
at
The Wistar Institute

Postdoctoral positions for 2 to 3 years are continuously available to exceptionally good recent MD and PhD graduates in the field of oncogenesis, cellular differentiation, chemical carcinogenesis, membrane biochemistry, somatic cell genetics, tumor cell biology and molecular biology.

Applicants should send their curriculum vitae and names of three references to:

Coordinator of Research Training,
The Wistar Institute
of Anatomy and Biology,
36th Street at Spruce,
Philadelphia, PA 19104. (NW329)E

Organon International bv

postdoctoral research fellowship in CNS-Pharmacology

The fellowship tenable for up to 3 years is available in the Scientific Development Group of Organon International bv, The Netherlands.
The successful candidate will work in the Behaviour Group of the CNS-Pharmacology Department.
The post will appeal to pharmacologists experienced in the field of animal models for aging, Alzheimers's disease and related pharmacology.
The company's extensive and well equipped laboratories are situated at Oss, in the southern part of The Netherlands.

Written applications, including curriculum vitae, a full statement of research experience and a list of publications should be sent to: Organon International bv, Personnel Department, P.O. Box 20, 5340 BH Oss, The Netherlands, under number HK 83-16. Requests for further information should be directed to Dr. C. Broekkamp, CNS Research & Development Laboratories, phonenumber (31)-4120-62801.

CONFERENCES and COURSES continued

ANNOUNCEMENT/CALL FOR PAPERS, POSTERS, AND REGISTRATION
CONFERENCE ON THE MOLECULAR BASIS OF CANCER: AN INTERDISPLINARY ON BASIC AND APPLIED ASPECTS OF CANCER
MAY 30 — JUNE 2, 1984
ROSWELL PARK MEMORIAL INSTITUTE, BUFFALO, NEW YORK

Invited speakers:

A. Block	Buffalo	G. Loew	Menlo Park
S. Broyde	New York	K. Miller	Troy
C. Cantor	New York	S. Neidle	London
E. Clementi	Poughkeepsie	T. O'Connor	Buffalo
D. Crothers	New Haven	W. Olson	New Brunswick
C. DeLisi	Bethesda	G. Pack	Rockford
T. Dougherty	Buffalo	M. Pincus	New York
W. Duax	Buffalo	P. Politzer	New Orleans
M. Feldman	Rehovot	A. Pullman	Paris
R. Feldmann	Bethesda	B. Pullman	Paris
I. Hertman	Ness-Ziona	R. Rein	Buffalo
A. Hopfinger	Skokie	R. Sarma	Albany
T. Hopp	Seattle	H. Scheraga	Ithaca
J. Kaufman	Baltimore	R. Schwartz	Bethesda
S. Kim	Berkeley	D. Stollar	Boston
P. Kollman	San Francisco	A. Wada	Tokyo
J. Ladik	Erlangen	R. Wells	Birmingham
M. Liebman	New York	C. Wenner	Buffalo

Organizing Committee: R. Rein (Chairman), C. DeLisi, P. Lowdin, T. O'Connor, B. Pullman, H. Weinstein

This conference will provide a forum for a dialogue on topics which are in the forefront of cancer research by investigators from various areas of natural sciences. The conference will bring together experimental biologists, theoreticians, and structural chemists for a discussion centered around gene function and expression, drug design, immunological probes, and membrane properties underlying the cancerous process.

The invited and contributed papers will be promptly published. Papers for the proceedings should be submitted no later than the finish of the conference. Abstracts are due by April 1 and should include the name of the author(s), institution and a summary of the work to be presented. Send to R. Rein, Roswell Park Memorial Institute, Cancer Cell Center, Buffalo, New York 14263.

The number of participants will be limited to 400. Inquiries about details of the program and registration should be addressed to Kevin A. Craig, Medical & Scientific Communications, Roswell Park Memorial Institute, 666 Elm Street, Buffalo, New York 14263. (NW320)C

The Scientific Affairs Division of NATO is sponsoring an Advanced Study Institute on:

CHROMOSOMAL PROTEINS AND GENE EXPRESSION

to be held at Sitges, Spain from 17 to 26 September, 1984.

The course is intended largely for post-doctoral researchers and advanced graduate students, but a limited number of independent investigators may also be admitted. Through lectures and tutorials, we will systematically discuss and analyze recently accumulated knowledge on the roles of chromosomal proteins in gene expression. Topics to be covered include: nucleosome and higher order chromatin structures, active gene chromatin structure, hypersensitive sites, histones, protamines, HMG proteins, scaffold proteins, Z-DNA binding proteins, promoter and enhancer elements, in vitro and in vivo transcription, DNA methylation, and DNA-protein interactions.

Lecturers: F. Azorin (Cambridge, Mass.), M. Beato (Marburg), C. Crane-Robinson (Portsmouth), G. Dixon (Calgary), S. Elgin (St. louis), G. Goodwin (London), C. Hélène (Paris), U. Laemmli (Geneva), P. Puigdomènech (Barcelona), G. Reeck (Kansas), D. Schumperli (Zurich), J. Subirana (Barcelona), J. Thomas (Cambridge), B. Wasylyk (Strasbourg), S. Wright (London).

Organizing committee: G. Reeck, G. Goodwin, and P. Puigdomènech.

Limited funds are available to subsidize some participants' expenses. Applications to attend the course and for financial support should be sent to Dr. G. Reeck (Kansas State University, Dept. of Biochemistry, Manhattan, Kansas 66506 USA) and should include a résumé, list of publications, description of research interest, rationale for wanting to participate in the course, and statement of financial need (including availability of other funds to support your participation). (1259)C

EMBO — Advanced Lecture Course Molecular Genetics of Mammalian Development

PAVIA — 3-15 September 1984

General topics: recombinant DNA techniques in development, germ cells, early development, dedifferentiation and its relationship to embryogenesis, developmental and temporal regulation of genes, tissue specific expression, somatic cell genetics as a tool, hormonal regulation of expression, promotors, enhancers and other regulatory elements, injection of foreign DNA into embryos and its expression, approaches in other animals.

Specific systems include: H-2, HLA and disease, antibody genes, muscle differentiation, nervous system, lens cell, X-inactivation, sex determination, the T/t locus, oncogenes and the cancer problem.

Lecturers include: C. Morandi, V. Sgaramella (Pavia, Italy), A. Carbonara (Torino, Italy), G. Tocchini-Valentini (Roma, Italy), G. Bulfield, R. Clayton, N. Hastie (Edinburgh, UK), A. McLaren, P. Goodfellow (London, UK), M. Lyon (Harwell, UK), P. Démant (Amsterdam, Netherlands), V. Pirrotta (Heidelberg, FRG), V. Chapman (Buffalo USA), K. Paigen (Berkeley, USA), P. Brûlet (Paris, France).

The Course will consist of lectures, seminars and journal clubs and its organised for EMBO by G. Astaldi Ricotti, C. Morandi, G. Della Valle (Pavia) and G. Bulfield (Edinburgh). The Course fee is $280 which includes all meals and accommodation. For further details and applications with brief CV and research interests by *1st June* (limit 60 people) to:

Dr Grahame Bulfield (EMBO Course 1984/9)
AFRC Poultry Research Centre
Roslin, Midlothian, EH25 9PS, UK.

(1280)C

UNIVERSITY OF SUSSEX

SCHOOL OF BIOLOGICAL SCIENCES

MSc COURSES IN BIOCHEMISTRY

The University offers four full-time one-year M.Sc. courses in Biochemistry: General Biochemistry, Biochemical Endocrinology, Genetic Manipulation and Molecular Biology, Plant Biochemistry and Bioenergetics and places on these courses are available for the 1984/85 session. In some cases a full-time 2-year course may be possible.

Research projects are included in each course, related to research currently underway in the Biochemistry Group, much of which is of relevance to developing countries.

Applicants should normally possess an Honours degree or its equivalent in Biochemistry or in a Biological, Chemical or Medical Science.

Enquiries and applications about these and other postgraduate courses in Biochemistry should be sent to the Subject Chairman of Biochemistry, School of Biological Sciences, University of Sussex, Falmer, Brighton, East Sussex, BN1 9QG. (1287)C

ADVANCED COURSE OF FIS AND SHELLFISH DISEASES I EUROPE

Sponsored by the Council Europe and UNDP/FA (Mediterranean Region) to be he at the Institute of Aquacultur University of Stirling, from Ju 17-29, 1984.

Lecturers and participants will from various parts of Europ Infectious and non-infectio diseases, therapy, control a economics will be included.

Further details from Dr Ja Polglase, Institute of Aquacultur University of Stirling, Stirlin FK9 4LA, Scotland, UK. Closi date for applications 1st May 198 (1291)C
